INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine. G., in *Biology of Bats* (ed. Wimsatt. W. A), Academic Press, New York. 1970. vol 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

Thar desert ecosystem

After C. V. Raman held an annual meeting in Rajasthan at Udaipur more than 50 years ago in 1945, the Indian Academy of Sciences revisited the State for the 62nd annual meeting which was held at Jodhpur from November 1 to 3, 1996. Continuing a long-standing tradition, a highlight of the Jodhpur meeting was a symposium of local scientific interest devoted to 'Arid Ecosystem of the Thar desert of Western Rajasthan'. The symposium addressed Thar desert's unique characteristics in the light of modern day science and technology developments.

The Thar desert (drawing its name from a district in Pakistan's Sind province, Tharparkar) is also known as the Great Indian desert and spans an area of approximately 259,000 km^2 in the Indian subcontinent, 69% of which lies in our country's north-western region.

The Thar desert experienced several periodic climatic changes from arid to semi-arid, resulting in the dominance of either the fluvial or the aeolian processes. These processes have dictated much of the present topography. Historical data suggest that, several millennia ago, the total atmospheric precipitation in the Thar was 4 to 5 times higher than at present. The enhanced aridity is believed to be responsible for the decline of the Harappan civilization about four millennia ago. Famines of various kinds, namely Akal (great famine), Jalkal (water scarcity), Tinkal (fodder scarcity) and Trikal (water, fodder and grain scarcity) have been a frequent occurrence. Their dispersion in the Thar is emphasized in a local Rajasthani saying:

'Pug Poongal, Sar Merte, Udraj Bikaner, Bhoolo Chukyo Jodhpur, Thayo Jaisalmer.'

Translated:

'Famine keeps its legs standing in Poongal region in the heart of the desert, its head in Merta, stomach in Bikaner, may move to Jodhpur and stay forever in its home town of Jaisalmer'.

The Thar desert population is mostly rural. The Western Rajasthan population density is 84 persons/km^2 and accounts for 38% of the total State's population. Although the population density is low compared to the other parts of the country, it is relatively high by arid zone standards. The livestock is around 25 million! These figures make this arid zone one of the most densely populated deserts of the world which implies considerable pressure on the region's natural resources. Thus, management of the natural resources assumes great importance. George Joseph of the Space Applications Centre provided in the first lecture of this symposium an analysis of the role of remote sensing in the resource management with special reference to Western Rajasthan.

The climate of the Thar is characterized by high atmospheric temperatures, which often reach 46°C and a strong wind regime with wind speeds up to 30 km/h, leading to a high evaporative demand (1500–2200 mm/year) and frequently to dust-raising winds, dust storms and associated wind erosion. The mean annual rainfall in the Indian region of the Thar desert is 345 mm varying spatially from less than 100 mm in the extreme western part (Jaisalmer district) to over 400 mm along the eastern fringe (Pali, Sikar and Jhunjhunu districts). D. R. Sikka, formerly of India Meteorological Department and Indian Institute of Tropical Meteorology, spoke at the symposium on desert climate and its dynamics.

Hydrologically the Thar desert could be divided into: (i) a region which has its major water source in more humid regions such as the northern districts of Punjab and Haryana and north-western parts of Rajasthan, (ii) plain lands with a primitive (or none) network of streams. The inhabitants of this region are partly dependent on surface water, i.e. harnessing the runoff in the form of village ponds and underground cisterns and largely dependent on groundwater having total dissolved solids of over 3000 ppm at a depth of 40–100 m, and (iii) sloping regions with an integrated stream network (e.g Luni river, its tributaries and many ephemeral channels that remain dry for a large duration). Overall, surface water resources of the Thar desert are extremely unreliable. A considerable fraction of the drinking water demand by both humans and livestock has to be met by drawing groundwater. S. M. Rao of Bhabha Atomic Research Centre who has carried out isotope studies on groundwater in Western Rajasthan presented results of his work at the symposium.

Despite the scarce water resources, about 45% of the total land area of the Indian arid zone is brought under plough every year. Rain-fed agriculture is practical in most areas. Productivity of traditional agriculture on these lands is poor due to low and erratic precipitation, high solar incidence, high wind velocities and poor soil characteristics. These arid areas suffer from shortage of traditional energy sources. Hence it is important to consider development of alternative energy sources such as solar energy, wind power and bio-energetics. S. P. Sukhatme of the Indian Institute of Technology, Bombay, made a detailed presentation of the efforts made and presently underway for generating electricity through photovoltaic and thermal routes from solar energy taking advantage of the high solar incidence over the Thar with the mean annual global solar radiation in excess of 6 kwh/m^2. (Jodhpur, the venue of the Academy meeting is known as 'Sun city' and receives more than 7 kwh/m^2 per day of radiation during April–June.)

Life exists in several forms in the desert. Desert flora are mainly of four types: (i) drought escaping, (ii) drought evading, (iii) drought enduring and (iv) drought resisting. The many varieties of cacti are typical examples of drought resisting desert flora. A wide variety of insects, reptiles, amphibians, birds and mammals enrich the desert fauna. While Mohan Ram of Delhi University delivered, in a separate session, a special lecture on plant life under extreme conditions, Ishwar Prakash, now at the Zoological Survey of India, presented a fascinating account at the symposium on the ecology of the desert mammals.

The five symposium presentations, which appear in a special section of this issue, offer a glimpse of the range of perplexing features and issues pertaining to the Thar desert, in the sustained development of which resides a magnificent challenge to the scientific community.

Essence of heavy hearts

The mammalian heart is a double pump. Each pump is provided with check valves to make it work in one direction and has a squeezable container, the ventricle and a filler, the atrium. William Harvey wrote in 1628: '... the blood in the animal body moves around in circle continuously and ... the action or the function of the heart is to accomplish this by pumping. This is the only reason for the motion and beat of the heart.' The pumping action of the heart results from shortening of muscle in its walls. The contraction of muscle produces the pressure that squeezes blood outward.

An incredible feature of this biological machine is that it is equipped with large factors of safety to meet the strains of every day life. A human heart pumps about 5–6 litres of blood per minute at rest. During strenuous muscular efforts such as running to catch a bus the output can go up to five times in a healthy adult. The heart does this by adjusting the rate of heart beat as well as increasing the volume of blood that comes out during one beat. From beat to beat, the output is regulated in response to muscle stretch. The more a cardiac muscle is stretched, the more vigorously it responds. This mechanism also helps in immediate adaptation when the valves of the heart become leaky due to disease processes. Leaky valves result in more blood in the ventricles, stretched muscles and more forceful contraction. However, continuous hyperfunction or sustained load needs other compensatory mechanisms to cope with the increased stress. Unlike other organs, heart is incapable of adding new units or multiplying its component cells. The basis of its growth is increase in the size of the muscle cells, i.e. hypertrophy. Hypertrophy is a phenomenon of normal growth of the heart. As body mass increases about 20 times from the time of birth to adulthood, there is proportionate increase in the cardiac muscle mass.

Both birth defects and acquired heart diseases can increase the load on the heart by either amplifying the resistance to cardiac output (pressure overload) or increasing the influx of blood into the heart (volume overload). In such situations, heart hypertrophies to increase the strength of contraction. A hypertrophied heart in some pathological conditions may weigh even one kilogram, 3–4 times the normal. Compensatory hypertrophy is a decisive factor for long term adaptation in a variety of heart diseases.

Though initially the hypertrophied heart is capable of meeting the increased work demands, during continuous hyperfunction, the reserves of the myocardial cells are successively mobilized until they are exhausted and function becomes severely impaired. Thus myocardial hypertrophy can be considered as an interface between normal and failing heart.

The hypertrophic response consists of not just an increase in muscle proteins. It is associated with re-expression of foetal genes and several proto-oncogenes. Significant increase also occurs in the number of non-myocyte cells, particularly the connective tissue cells, as well as collagen and other extra cellular matrix components.

Thanks to the use of cultured myocytes, transgenic animals in which hypertrophy is induced and application of recombinant DNA techniques, several questions regarding cardiac growth are being explored. Many questions have been answered and some remain to be elucidated.

What is the signal that transduces wall tension into cardiac growth? How is the signal from the cell surface mediated to the nucleus? What factors initiate and maintain protein synthesis? What is the role played by hormones and growth factors? These questions are addressed by D. S. Reddy in his review article (**page 13**).

There are three reasons for the study of mechanisms of cardiac growth: (i) understanding the circumstances that lead adaptive cardiac growth to pathological hypertrophy and heart failure is expected to lead to a clinical cure for cardiac failure, (ii) knowledge gained on cardiac growth may provide clues to augment cardiac muscle growth in injured myocardium. If cardiac growth can be induced by use of growth factors, it will also be of benefit in modulating long term adaptation of the heart, (iii) the model of compensatory hyperfunction of the heart is viewed as an ideal one for the study of inter-relationship between function and the genetic apparatus, a key element of long term adaptation in physiological systems.

EDITORIAL

An uncertain future

Support for science, both financial and otherwise, is diminishing in India as government's perceptions about the role of the science and technology enterprise in future development, appear to have changed rather rapidly. Higher education in science is threatened by the prospect of institutions having to raise funds from private sources to meet essential running expenses, even as government slowly abdicates its responsibilities in this area. Research departments and institutions can hardly compete for private resources, with management and marketing institutes and colleges and universities distributing engineering and medical degrees. The heady days of enthusiastic government support for science appear to be over. Unfortunately, the rationale for changing policies is often obscure, although budgetary compulsions are always blamed for across the board, non-discriminatory cuts in all areas of governmental expenditure. The uncertainties of the new year, which coincides with the start of a new Five-Year Plan, put together by a disparate coalition of interests, cast a long shadow on the future of scientific institutions in this country. While the defence science, space and atomic energy establishments will undoubtedly come through unscathed because of their perceived strategic importance, the rest of India's science institutions face difficult times ahead.

In most places, frozen budgets over the last few years have seen an ever increasing proportion of the allocated funds (in some cases as high as 90%) going towards payment of staff salaries and allowances, leaving little or no institutional support for research activities. Individual researchers survive largely on sponsored projects, which are of course easier to obtain and operate in a relatively small number of high profile institutions. Even here the decline is clearly visible. Projects submitted to government agencies lie for increasing lengths of time, unattended. Even more depressingly, release of funds for sanctioned projects proceeds at a glacial pace. The ever present battle for turf, an enchanting pastime for bureaucrats in Delhi, appears to have tilted against the managers of the science departments. Procedural delays are now the rule rather than the exception. Ironically, liberalization is a word that seems absent in the lexicon of bureaucracy, both in Delhi and inside our institutions. The pity is that by slowing the process of procurement of equipment, materials and staff appointments, most projects eventually end up costing more. In recent times, there has been much comment about the gradual aging of the scientific work force. Limited recruitments over several years have resulted in a graying of our laboratories. What appears to have passed unnoticed is that aging is a phenomenon that has also caught up with the middle level management of our science ministries.

Funding and encouragement for science may be at a low ebb, but it is also true that many of our agencies and laboratories are largely devoid of good ideas. Collective enthusiasm, which facilitates problem solving, is conspicuous by its absence. Innovation is rare and hardly encouraged by an unresponsive and conservative environment. The scientific establishment today suffers from poor public relations; an inability to enhance the public (and political) perception of what science in India has achieved and even more importantly the crucial contributions that it will make in the future. The herbal petrol fiasco highlighted dramatically the public craving for quick, magical fixes to mounting problems. The faith in conventional science obviously, does not run too deep.

Most non-performing wings of government get a far larger share of the public cake than the science departments. Scientific institutions most often struggle with limited budgets and unrealistic expectations of what can be achieved. Science, technology and higher education need a broad based lobby, which will prevent skewed priorities and ill thought out development strategies from cutting at the roots of our scientific and technological development. It is also clear that scientific institutions must devise mechanisms to shed some fat. Leaner and fitter organizations are more likely to cope successfully with an uncertain future.

P. BALARAM

Herbal medicines – some more reports

Several problems associated with the use of Herbal Medicines (HM) were discussed earlier in this column. Presence of toxic materials in HM, quantitative variation of the constituents from batch to batch of the plant products and alleged admixing of allopathic medicines with the herbal formulations by the manufacturers have raised serious concern among the medical scientists about safety of the patients[1,2]. A couple of subsequently published reports, highlighted here, reveal some other difficulties in the safe use of HM.

A herbal stimulant named Ma Huang claimed to be a mood enhancer and an aphrodisiac has recently been attributed to the death of 15 persons in the US[3]. In another case a person, who had no history of mental illness, became paranoid after taking Ma Huang for 10 days and jumped from an upstairs window with the fear that he would be killed by some supposed attackers. Fortunately he sustained only minor injuries. The formulation is known to contain ephedrine which is used as a nasal decongestant and bronchodilator but can cause psychosis among other complications when used in overdose. There was no mention of ephedrine in the leaflet of the product. On being contacted, the manufacturers failed to answer how much ephedrine was present per tablet[4]. This lack of information in the product literature of HM is a major problem for the patients throughout the world. Allured by the advertisements in the public media (as it happened in the second case) they buy and take HM and sometimes incur a lot of additional problems.

There is also reason to be worried about the microbiological and parasitological quality of the HM. A couple of months ago, some researchers detected harmful parasites in a sample of fish used to give an Ayurvedic medicine to thousands of asthmatics every year on an auspicious day of June[5].

It must be emphasized that nowhere in the world do the scientists deny the immense potential of the HM to complement the western medicines, but the question of safety of the patients cannot be relegated to the background. In this context it is worthwhile to note the comments of a reviewer 'A hundred years ago a pharmacist might sell you opium mixture, very likely adulterated. Now all over-the-counter medicines are regulated, and it is time "alternative" ones were as well'[6].

Biobatteries

The report on 'Biobatteries' was not properly vetted by *Current Science* before being published (*Curr. Sci.*, 1996, **71**, 92–93). To say the least, there is little or no novelty in that report, the 'biobattery' developed with fruit juices being just a version of the simple Daniel cell. The extensive references to biomass conversions included in the report notwithstanding, one can easily see, from an elementary knowledge of how electrochemical cells work, from what can be gathered from 'How Things Work' encyclopaedias or even from secondary school science classes, that the electric energy is drawn, not from the 'juices' through some direct biochemical process, but from zinc, when it is corroded by those juices, the energy having been put into the zinc, in the first place, when it was smelted from its ore by reduction to the metal stage through a high-energy metallurgical process*.

Years ago, when the transistor radio was new, it was demonstrated that one such radio, equipped with earphones, can be operated by means of a 'cell' made of copper and zinc American one-cent coins separated by a piece of newspaper moistened with saliva (1943 one-cent coins were minted out of zinc, instead out of the usual copper, in order to conserve the latter for the 'war effort'; the few copper 'pennies' that were minted in 1943 are now numismatic collector's items, worth millions of dollars, I am told!). The principle was, of course, that of the Daniel cell – as zinc ionizes into the 'juice' or saliva (abundantly available in Indian streets!), the released electrons flow through the wire or connected apparatus from the cathode (zinc) to the anode (copper). In modern 'lithium batteries' lithium metal serves, instead of zinc. The function of the 'juice' is to act as an ion transport medium with an 'overvoltage' sufficient to prevent the electrons from engaging in a direct reaction near the zinc, without producing a 'current' said to 'flow' from the anode to the cathode. The reaction ensuing the arrival of the electrons at the anode is one of producing hydrogen by a process of reduction. The current tends to fall off, however, when the copper gets covered over by a film of gaseous hydrogen. This is the so-called 'polarization' of the simple Daniel cell. No wonder, then, the authors find it necessary to clean the electrodes (especially the copper anode) 'frequently' in order to restore the potential to the 'fresh' value (incidentally, what is the meaning of values of current (in mA) given in the tables? Were they measured with the electrodes 'shorted'?).

'Polarization' is avoided by oxidizing off the hydrogen. In a Leclanche cell, where the 'electrolyte' is moist ammonium chloride, the oxidizing agent is manganese dioxide packed around the anode, a graphitized carbon rod as in a

---

*These comments apply also to a 'battery' using slurry from a biogas generator, described by the CIAE, Bhopal; see Mital, K. M., *Biogas Systems – Principles and Applications*, New Age, New Delhi, 1996, pp. 285–286.

torch cell you throw away when once the zinc casing has mostly dissolved away.

I am not certain of the ergonomics of the 'biobattery' but it would really have been impressive if the authors had considered the possibility of methane being cogenerated with the hydrogen near the anode and managed to demonstrate either that it happens or that it does not. If methane is formed at all under the relatively aerobic conditions of the 'biobattery', it would have been an 'advance' on (not really a mimic of) the as yet poorly understood process of biomethanation which takes place only under the exclusively anaerobic conditions of the rumen (of cows, sane or insane) or biogas digestor. Or, there would have been real novelty to the authors' efforts had their aim been to isolate and immobilize an oxidizing enzyme from a natural source, one that utilizes oxygen from the air to oxidize the hydrogen produced near the anode. Commercially viable or not, replacing manganese dioxide by such an enzyme for overcoming 'polarization' would have been a real breakthrough for developing a 'biobattery'. Maybe, the electric eel has all the answers – it utilizes energy from combining what it ate of the prey that it has stunned with an electric shock with the oxygen dissolved in seawater, having met the challenge of inventing a true 'biobattery' millions of years ago!

of Science Campus,
Bangalore 560 012, India

This is with reference to the article 'Biobatteries to utilize bioenergy from fruit and vegetable wastes'. The item is misleading because the source of electrical energy in these batteries is the dissolution of Zn. The standard potential for the CU/Zn couple is 1.1 V and it is not surprising that when these two electrodes are immersed in a paste of vegetable or fruit waste, a current is observed. The readers of *Current Science* deserve better.

R&D efforts in industry – National awards for 1996 presented

In order to provide recognition to the efforts of industry towards innovative research and technological development, the National Awards for R&D efforts in industry were instituted in 1987 by the Department of Scientific & Industrial Research (DSIR). These awards are in the form of silver shields and are presented along with citations at the inaugural session of the 'National Conference on in-house R&D in Industry', held annually by DSIR.

Professor Yogendra Alagh, Union Minister of State for Science & Technology presented the shields on 10 December 1996 in New Delhi to the following seven winners of awards for 1996:

- **Armour Polymers Limited, Mumbai**, for the development and commercialization of the amoxidation process for the manufacture of cyano pyridines.
- **Hetero Drugs Ltd., Hyderabad**, for overall bulk drugs and intermediates.
- **Lamco Lightning Arrester Mfg. Company Pvt. Ltd., Hyderabad**, for the development and manufacture of lightning arrester disconnectors.
- **Patwa Kinarivala Electronics Ltd., Vadodara**, for the development of a range of instruments and electronic control systems for the textile industry.
- **Titan Industries Limited, Hosur**, for the design, development and commercialization of ultra-thin quartz analog watch movements.
- **Ankur Seeds Pvt. Ltd., Nagpur**, for breeding superior hybrids of cotton, okra, chilli, brinjal, cucurbits and sunflower.
- **Jain Irrigation Systems Ltd., Jalgaon**, for fully absorbing technology, imported for micro-irrigation and sprinkler systems, and improving it by their own R&D.

RESEARCH NEWS

Vaccine production in transgenic plants

P. Suprasanna, T. R. Ganapathi and P. S. Rao

The development of novel techniques of tissue culture and molecular biology to genetically transform plant species has revolutionized plant biology, and there is an enormous interest to design and produce plant species with desirable characteristics such as insect resistance, disease resistance, herbicide tolerance and delayed fruit ripening. The notable achievements in these areas led to explore the possibilities of employing transgenic plants with modified biosynthetic potential for new products[1]. Biologically active peptides and proteins have many potential pharmaceutical applications including use as vaccines, immuno-modulators, growth factors, hormones, blood proteins and enzymes[2]. There has been a recent interest in this direction in producing functionally active proteins, peptides of medical importance, in transgenic plants. On a global scenario, the developing countries are often the target of several infectious diseases. Preventive medicine (for example, vaccines) has proceeded rapidly in the last decade as biotechnology has been applied in several areas. These medical

- Purified protein is sufficient to promote immunity to the disease.
- Purified protein is orally immunogenic.
- The gene for the protein is cloned.
- The protein maintains its antigenic epitopes and assembles into its native form when expressed in a heterologous system.

B. Factors to consider in selecting a gene for plant expression systems
- Modification of the gene with plant specific regulatory elements.
- Analysis and reconstruction of antigen-coding sequence for optimal plant expression.

C. Create a plant transformation vector

D. Transform plant tissue

E. Generate plants for analysis

F. Analyse recombinant protein for antigenic epitopes and proper assembly within plant tissue

G. Optimize production of recombinant protein in plant tissue by redesign of gene or transformation vector

H. Test oral immunogenicity of the vaccine-containing transgenic food
- Test for induction of an immune response to the recombinant protein.
- Challenge immunized animals (if possible) with the disease to determine if the candidate vaccine can induce a protective immune response.

Figure 1. Production of candidate vaccines in plants is shown schematically along with factors to consider for various steps. (From Richter *et al.*[5]; Reproduced with permission from Dr C. J. Arntzen.)

advances are not likely to have significant impact in developing countries because of prohibitive costs of production and delivery of the recombinant proteins which comprise the new vaccines (Arntzen, pers. comm.). The economic conditions and inaccessibility to world markets also limit the use of vaccines for immunization to large population. In this regard, the concept of vaccine production in transgenic plants assumes greater significance for a relatively low-cost, agriculture-based system, rather than the sophisticated and expensive cell culture and fermentation-based vaccine production.

The concept was first introduced by Charles J. Arntzen and his group in a report of vaccine production in tobacco plants genetically engineered with plant-derived recombinant hepatitis B surface antigen (rHBsAg) (ref. 3). In this study, they have demonstrated that the HBsAg was expressed in tobacco and the partially purified protein when injected into mice, elicited antibody response, similar to that obtained with 'recombivax' (a commercial hepatitis B vaccine). This study clearly demonstrated close-relatedness of the antigens and also the potential of producing immunologically active vaccines in transgenic plants.

Potential recombinant vaccines for viral and non-viral organisms have been produced in transgenic plants. Norwalk virus causes epidemic, acute gastroenteritis. The recombinant capsid protein (NVCP) was expressed in transgenic tobacco leaves and potato tubers[4]. The capsid protein could be extracted from tobacco leaves in the form of 38 mm Norwalk virus-like particles. rNV expression levels up to 0.23% of total soluble proteins in tobacco leaves and up to 0.37% in potato tubers were obtained. The partially purified recombinant NVs from tobacco were given orally, and potato tubers expressing NVCP were fed to mice. In both the cases, stimulation of antibody (IgG) specific to rNV was noticed. This study also demonstrated that oral consumption of recombinant plant tissues can evoke specific immunoglobulin production, furthering the concept of 'edible vaccines'.

In another study[5], tobacco and potato were transformed with genes encoding the binding subunit of *E. coli* heat labile entero-toxin (LT-B). Worldwide, enterotoxigenic *E. coli* and *Vibrio cholerae* cause acute watery diarrhoea by colonizing the small intestines. Transgenic plants having the LT-B gene expressed the protein similar to the bacterial protein. Transgenic tubers when directly fed to mice, elicited the development of both serum IgG and mucosal IgA antibodies to LT-B, in contrast to no LT-B specific antibodies in mice fed with non-transformed tubers.

Research on transgenic plant-based production of vaccines has just begun and already studies on optimization of accumulation of recombinant proteins in edible plant tissues and feasibility including economics of such approaches are being made. These investigations generate a hope towards developing low-cost edible vaccines from plants that are commonly available, compared to expensive recombinant vaccines. In order to be applicable to large section of population in a edible and un-cooked form (to ensure, there is no denaturation), production of vaccines in candidate crops like banana can be invaluable to many tropical countries in the developing world where these are grown, richly available at lower costs and consumed as staple food.

SCIENTIFIC CORRESPONDENCE

Assessment of plant bio-diversity at Kalakad–Mundanthurai

T. Ganesh *et al.* (*Curr. Sci.*, 1996, **71**, 379–392) have generated interesting phytosociological information for the Tiger Reserve in the Agasthyamalai range.

While highlighting the importance of quantitative analysis in an area of 3.82 ha, the pioneering work of Champion[1] and Puri *et al.*[2] is referred to as based on qualitative criteria such as physiognomy and dominant species, ignoring quantitative data.

Champion's treatise on the vegetation types came out in 1936, later on revised by Champion and Seth in 1968 (misquoted as 1936 in the reference). This study covered the entire sub-continent. The idea was to come out with a classification good for the country as a whole, with spot descriptions. Significantly, Champion chose to call his *magnum opus* 'a preliminary survey'. Had he confined himself to small plots with quantitative statistics, the concept of which barely existed in his time, perhaps, the publication would not have yet seen the light of the day.

Contribution of Puri *et al.* of a later date (1983) relies on the vegetation maps of the French Institute at one millionth scale based on the criteria of dominance–abundance–fidelity of species. The series recognized for the Kalakad–Mundanthurai region is *Cullenia–Mesua–Palaquium*. It is within this series that the quantitative study has established *Cullenia–Alagaia–Palaquium* sub-type considering an area of 3.82 ha.

The question is for how large an area would this sub-type remain valid, latitudinally and altitudinally? How many subtypes founded quantitatively go into one series, viz. *Cullenia–Mesua–Palaquium* of the southern part of the Western Ghats? How many hundreds (or thousands) can be counted in Peninsular India? What is good for a 4 ha study carried out in considerable detail may not be manageable at the level of the sub-continent. The question of scale should not be lost sight of.

Reply by T. Ganesh et al.:

We recognize the pioneer and monumental contributions of Champion[1] and Puri *et al.*[2] to the description of forest vegetation in India, but reiterate that plant ecologists in India must move beyond qualitative description of vegetation, particularly in light of the current need for assessment and monitoring of biodiversity. Our paper represents an effort towards quantification of tree diversity in an area that is poorly known, but has a high level of biodiversity. Incidentally, Meher-Homji and his colleagues, notably Pascal[3] from the French Institute, themselves have been pioneers in collecting quantitative data on the distribution of tree species in plots throughout the Western Ghats.

We also wish to point out that the 3.82 ha that Meher-Homji refers to is a sub-sample of an area over 100 ha. Nevertheless, his question for how large of an area would this sub-type remain valid is an appropriate one. Although we recognized the forest type as *Cullenia–Aglaia–Palaquium* type, we did so in the context of types and sub-types established by Champion and others. We now feel that the concept of types and sub-types based on dominance of certain species is of limited utility, and may not be valid in many cases. Plant communities change over time and space. The static description of vegetation does not capture the dynamics of natural communities. Understanding dynamics is key to long-term conservation of biodiversity. In fact, one of the points of our paper is that our results do not conform to the vegetation described for the area because the vegetation is expected to vary over small spatial scales. Therefore, quantitative studies are required to document patterns of diversity and long-term monitoring is essential to understand dynamics. Regrettably, in trying to make our point about changes in community structure over space and time, we fell into the trap in claiming the existence of another subtype. Thus, we are very grateful to

Meher-Homji for providing an opportunity to not only clarify the points raised, but also to state our position concerning vegetation types.

Electrostriction effect and solvent engineering

Anil Kumar on application of ion–solvent interaction and thermostability of DNA duplex in ionic solution (*Curr Sci.*, 1996, **71**, 289) highlights many important findings which bear relevance not only to DNA but are very much true for proteins and enzymes. The kinetic data presented clearly explain the thermostability acquired by DNA in ionic solution. Interestingly, similar role of electrostriction effect is indicated from several reports on enzyme stability by soluble additives, e.g. salts, sugars and sugar alcohols.

Nowadays the area of thermostability of enzymes is a challenging field for chemists, biochemists, biotechnologists and industrial microbiologists. Lot of work has been directed to achieve this by stabilization of native confirmation of protein in aqueous environment. T_m of lysozyme and ribonucleases and many other enzymes has been raised using sugars and polyols. Thermolabile enzyme preparations have been stabilized by high ionic strength solutions. The role of viscosity, intensification of the intramolecular hydrophobic interaction within the protein reduced volume and increased surface tension has been advocated in protein solvent and additive interactions[1].

The possible role of electrostriction (ES) effect leading to a hydrophobic environment in an aqueous system in enhancing the shelf life of enzyme, altering substrate specificity and rate of reaction, opens up new vistas in solvent engineering of enzyme mediated reactions.

Anil Kumar replies:

Gupta and Saxena have offered valuable information on the role of electrostriction in explaining several biological processes. We often stress, in the seminars and symposia about effective and fruitful collaboration among biochemists, microbiologists and biophysicists. The time has now come that we, in India define the areas of collaboration and intensify collective efforts to work on the solvent engineering of enzyme-mediated reactions.

Dengue haemorrhagic fever epidemic in Delhi

Dengue was endemic in India, but dengue haemorrhagic fever (DHF) is of recent origin, first reported[1] from Calcutta in 1963. Since then DHF and dengue shock syndrome (DSS) have been occurring in India sporadically and entering urbanized and industrialized settlements. DHF/DSS epidemics have also been reported from purely rural villages in Maharashtra, Karnataka, Tamil Nadu, Delhi, etc. Urbanization and rural water supply are the principal reasons for *Aedes* dispersal. So far there have been 70 reported outbreaks in the country and the 1996 epidemic was preceded by 6 outbreaks in Delhi. All four serotypes (Den-1, Den-2, Den-3, Den-4) occur in India. In the 1996 epidemic Den-2 virus has been isolated by Pradeep Seth at the All India Institute of Medical Sciences, New Delhi and Kalyan Banerjee at the National Institute of Virology, Pune. The epicenter of DHF was south Delhi affecting all communities, and later cases were reported from almost all localities. In this epidemic beginning in August, the government has reported 8900 cases and 375 deaths due to DHF. Reported cases may be the proverbial tip of the iceberg. Dengue fever and deaths are also being reported from neighbouring towns in Haryana and Uttar Pradesh. Dengue now occurs across the country with increasing reports of DHF/DSS. Army's help was sought, but ironically deaths and large number of admissions due to DHF were also reported from the New Delhi military hospital. The epidemic has receded with the onset of winter but DHF is known to become endemic, and might resurface periodically. In Delhi *Aedes aegypti* breeds profusely with larval index from 20 to 40 or more in many localities, particularly during the transmission months following rains. Breeding opportunities for *Aedes aegypti* are enormous and evenly spread in most Delhi in the form of desert coolers, water storage tanks, leaking water supply, fountains, wells, tire dumps, and rain water collection on roof tops and a variety of receptacles. Vector control under the urban malaria scheme is erratic and limited to some localities by way of spraying of larvicides in surface drains, temephos treatment of water tanks and thermal malathion fogging. Field operations are wanting and mainly targeted to control *Culex* breeding. Malaria is endemic in Delhi and the vector *Anopheles stephensi* and *Aedes aegypti* largely share similar breeding habitats. DHF epidemic coincides with *P. falciparum* prevalence making diagnostics a problem. Dip-stick test[2] for *P. falciparum* would be desirable. While malaria is treatable, there is no specific treatment for viral infections. In dealing with DHF preventive vector control is the key to success. This is attainable by a well-organized *Aedes* control programme. The control of *Aedes aegypti* by chemical methods like spraying and fogging or ULV application is not productive and sustainable[3], except epidemic control[4]. *Aedes* control requires strong entomological support which is weak in the states and almost non-existent in the municipal corporations and smaller bodies[5]. The disease has come to stay and governments would do well by emphasizing community participation and taking help of legislative measures. The approach to DHF control should be community based directed towards species sanitation and learning from the DHF endemic countries.

Sex and the single X

In mammals, including human, it is believed that the Y chromosome by its presence or absence exerts a series of actions upon which develop the sexually dimorphic characters. Although a number of genes in this cascade of binary decision might be autosomal or X-chromosomal, there must be one or more gene(s) on the Y chromosome to govern the process of testis determination if the male development is a dominant pathway.

SRY is the only gene that is required on the Y chromosome for testis determination as the introduction of transgenic *SRY* alone into chromosomally female mice results in male development[1]. Recently a few autosomal genes have been identified that are probably involved in testis development. For example, mutation in *SOX9* gene is associated with XY sex reversal in human[2] and the null mutant for the gene *SF-1* shows severe abnormalities in the gonadal development of mice[3]. In contrast to our current understanding of the process of male development in mammals, the genetic cascade of the female pathway is almost completely unknown. It is possible that in some of the XY females, a 'loss-of-function' mutation in a gene that inhibits ovarian development (in males) could have been the cause for sex reversal. Although chromosomal deletion in 9p and 10q is associated with such XY females, interruption of testis development was viewed as the cause for sex reversal having led to the female development by default[4]. However, that the ovarian differentiation may not be a passive one is indicated by the fact that in wood lemmings, rearrangement in an X chromosome induces the development of reproductively active XY females even in the presence of a normal Y chromosome[5]. More interestingly, in two species of mole-vole, sex determination is in the absence of Y chromosome (XO male; XX female)[5,6]. The first indication for involvement of an X chromosomal gene in human sex determination was provided by the identification of a family with an X-linked mode of inheritance of 46,XY sex reversal[7]. Demonstration of duplication in short arm of the X chromosome (Xp21 region, called the *DSS* locus) in such 46,XY females raised the interesting possibility that the duplicated X chromosomes cause XY sex reversal by expressing double dose of a gene normally subject to X inactivation[8]. However *DSS*-negative 46,XY males develop testis and show normal external genitalia, indicating *DSS* is not involved in testicular development[8]. Therefore, it is puzzling to imagine how the inactivation of X chromosome and the dosage activity of this locus control gonadal development.

Recently Jimenez *et al.*[9] discussed an appealing model for the dosage effect of *DSS* speculating a female determining function for the *DSS*. It is proposed that in normal female the *DSS* down regulates autosomal genes involved in male development (e.g. *MIS*) but the autosomal factors are not inhibited in the 46,XY males owing to the suppressive action of *SRY* on *DSS*. Thus, testis development implies inhibition of female pathway genes and for the ovarian development, the male pathway genes must be suppressed. Therefore, deletion of *DSS* does not affect male development. However the duplication of *DSS* in XY individuals [46,XY *dup*(Xp)] renders the level of SRY protein insufficient to suppress the two active doses of *DSS*, thus leading to development of female phenotype. It is likely that such a dosage effect might have been the primitive mechanism of sex determination in mammals and that *SRY*'s role is a recent addition because some of the events of sexual differentiation in the primitive mammals, marsupials, are based on the ratio between X chromosome and autosomes[10]. In fact the effect of dosage in sex determination has earlier been shown for birds (the group that diverged from the same ancestral stock of mammals) although here it is based on the Z chromosome to autosome ratio[11]. Therefore, Chandra, by extending his original hypothesis on dosage effect in mammalian sex determination, viewed the absence of dosage compensation for Z chromosome as a key factor in the avian sex determination[12].

While the *DSS* dosage model[9] is attractive because it resolves the paradox of 46,XY *dup*(Xp) sex reversal and offers an evolutionary perspective as stated above, but the support for this model at present is very little. Moreover there are a few points to be considered before suggesting such a sweeping role for *DSS*. First, there is no evidence for *SRY* to be an inhibitor of *DSS*. Should that be so in all the mammals then, in the mole-vole *Ellobius*, which lacks Y chromosome and *SRY* (ref. 6), there should be no males. Likewise, in human while *DSS*-negative males are normal, the effect of such a genotype on genetic female is not clear due to the random X-inactivation. Moreover the proposed negative regulatory role of *MIS* (a male pathway gene) on 'female pathway genes' and of ovarian germ cells on 'male pathway genes' in sex differentiation is questionable since in the *MIS*-deficient mice, testis is spermatogenically active[13], and the gonadectomized females are phenotypically normal with little obvious effect of the absence of germ cells[14]. A role for *DAX-1* (the gene which falls in the *DSS* region and code for a nuclear receptor) in gonadal determination is not clearly established since no rearrangements in *DAX-1* could be detected in thirty 46,XY females[7]. Nevertheless, the occurrence of *DSS*-deleted males and duplication of *DSS* in 46,XY females emphasize that *DSS* is necessary for ovarian development and may be repressed in XY individuals.

The recent progress in the identification and characterization of genes like *SF-1*, *SOX9* and *WT1* (ref. 16), which show multiple functions in addition to their role in gonadal differentiation, reveal a multi-factorial hierarchy in the cascade of gonadal determination. Moreover, testis development in XX–XY chimeras with atleast 25% XY cells[17], high incidence of XX sex reversal for *SRY*-transgenes in homozygous condition rather than in hemizygous, correlation of incomplete penetrance of *SRY*-transgene with a lower level of its transcripts[16], and duplication of *DSS* and XY sex reversal[8], all suggest a concentration threshold for sex-determining factors in the gonadal development. Therefore, it is reasonable to explain that, instead of assuming the 'one-gene one-function' role of *SRY* in suppressing only the *DSS*, there may be opposite and competitive (indirect?) effects of *SRY* and *DSS* likely on one or more critical factor(s) whose concentration may determine the gonadal switch. Doubtless the switch must function in association with other factors as well as their developmental timing. Further experiments including the construction of animals carrying additional copies of *DAX-1* will be required to understand the process of ovarian determination and the role of *DSS* in it. It may also lead to the discovering of putative additional factors. Moreover the 'default' pathway of ovarian development in mammals should be reconsidered to identify critical genes for ovarian determination, if any.

Cellular and molecular biology of cardiac hypertrophy

D. S. Reddy

Department of Pharmacology, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh 160 014, India

Cardiovascular system at the cellular level adapts to chronic haemodynamic changes by altering gene expression. Cardiac cell-specific expressions of many contractile protein genes are regulated at the transcriptional level by the interaction of activator proteins with specific *cis*-acting sequences. A number of positive and negative *cis*-acting elements from upstream of the basal promoter region and some of their *trans*-acting protein binding factors have been characterized. Recent epidemiological studies implicated left ventricular hypertrophy (LVH) as a premonitory symptom of mortality from many cardiovascular complications. Although cardiac hypertrophy by a chronic haemodynamic overload *per se* is not a pathological rather biological adaptive response of heart, heart failure as a final form of hypertrophy is an obvious disorder producing high mortality. Qualitative changes in the actin-myosin genomic expression such as re-expression of fetal isoforms, through the induction of immediate-early genes (proto-oncogenes), allow the hypertrophied cardiac fibre to develop a normal active tension to the sustained load at the cost of its maximal shortening velocity, thus inducing a pathological state. Multiple lines of evidence support the existence and functional integration of a variety of humoral factors within the heart, and may participate in the genesis of LVH. The renin–angiotensin system (RAS) has been suggested to play a pivotal role in the regulation of cardiac cell growth and LVH. Other humoral mechanisms such as sympathetic nervous system and endothelin vasoconstrictors have also been implicated. Thus, the elucidation of the cellular and molecular biology of normal cardiac growth, development and hypertrophy may hopefully lead to the development of novel therapeutic strategies to cardiac failure.

CARDIAC hypertrophy (CH) is the pathophysiological adaptation of the heart to chronic mechanical overload, in conditions such as essential hypertension, valvular heart diseases and myocardial infarction. Recent epidemiological studies implicated left ventricular hypertrophy (LVH), detected as an increased ventricular muscle mass, as a premonitory symptom of mortality from many cardiovascular complications. Although hypertrophy by a chronic overload *per se* is not a pathological rather biological adaptive response of heart, heart failure as a final form of hypertrophy is an obvious disease causing high mortality. Qualitative changes in genomic expression allow the hypertrophied cardiac fibre to develop a normal active tension to the increased load at the expense of its maximal shortening velocity (V-max). These changes are preceded by the temporary expression of proto-oncogenes, isogenes of proteins of contractile apparatus and the re-expression of 'fetal' isoforms.

In recent years it has become clear that a variety of hormones are present in the heart and may participate in genesis of LVH. Mechanical load or stretch in cardiac tissues has been identified as a growth stimulus. For several years, humoral mechanisms such as the renin–angiotensin system (RAS) and the sympathetic nervous system have been speculated to play a role in the regulation of cardiac cell growth and hypertrophy. Extensive studies from our laboratory[1–8] have demonstrated the contribution of angiotensin systems in the pathogenesis of several cardiovascular disorders, particularly the ventricular hypertrophy and failure. Other factors that have been postulated include endothelins, thyroxine, cortisol and various peptide growth factors[2,3]. Atrial natriuretic factor (ANF), nitric oxide (NO), and specific prostranoids may negate and balance the actions of various ionotropic agents[3], and contribute to the cardiovascular homeostasis. The elucidation of the cellular, molecular biology of normal cardiac growth, development and hypertrophy is of vital interest to cardiovascular biologists to reveal the pathobiology of congenital cardiovascular defects, maintenance of normal structure and function, and pathogenesis of cardiac muscle failure, which permits to develop newer therapeutic strategies to cardiac failure. As a consequence of the newly developed techniques of recombinant DNA and genetic manipulation, as well as molecular biology based antisense oligonucleotide probes[9], the understanding of the cellular and molecular biology of the heart, particularly hypertrophic growth is receiving widespread attention in the field of cardiovascular medicine. The present review briefly updates our understanding of cellular and molecular biology of cardiac hypertrophy and proposes potential pharmacological interventions for the prevention and regression of left ventricular hypertrophy.

Cardiac growth and development

During the last decade, a variety of morphological, physiological and biochemical studies have provided an improved definition of the alterations in myocardial structure and function that herald the sequential stages of cardiac growth and development. Cardiac growth process can be divided into three categories: embryonic cardiogenesis, post-natal development and hypertrophic adaptation[10]. The first two occur in normal developmental process, and hypertrophic growth is induced by hemodynamic overload.

Cardiogenesis starts with a proliferation of mesodermally derived progenitor cells and commitment to the cardiac muscle cell lineage[11,12], which is followed by differentiation to form a primordial heart tube. The heart tube consists of an outer layer of cardiac muscle cells and an inner layer of endocardial cells. Subsequently, the heart tube acquires an S-looped configuration. At this stage, bulbar, ventricular, atrial and sinus venosus can be distinguished[13]. Eventually, organogenesis proceeds through a series of involutions of heart tube and the onset of septation resulting in distinct cardiac chambers, outflow tracts and the acquisition of regional-specific properties of atrial, ventricular and conduction system cells. The subsequent enlargement of embryonic heart is largely due to myocyte multiplication, which continues until shortly after birth, when cardiac myocytes lose their proliferative capacity and acquire the terminally differentiated phenotype of adult cardiac muscle cells[14]. Acquisition of the divergent morphological, electrophysiological, biochemical and contractile properties of specialized cardiac cell type is largely because of the activation of regional specific programme of gene expression[15].

Recent studies, applying immunohistochemical and *in situ* hybridization techniques to genetic markers have provided some clues to the sequence of molecular and cellular events in cardiogenesis[16–19]. Genetic markers may be viewed as the final step in the molecular pathways that control the complex processes of commitment and regional specifications. Cardiogenesis related to the time of occurrence of atrial and ventricular specificity has attracted much attention. Lyons *et al.*[20] have provided initial insight into the events that lead to cardiac muscle gene expressions into atrial and ventricular specification in adult myocardium. Genes that are differentially expressed in atrial and ventricular tissues like ANF, myosin light chain-1_A (MLC-1_A) which are atrial specific and myosin light chain-1v (MLC-1v), β-myosin heavy chain (β-MHC) which are ventricular specific, are candidates to be used as markers to study cardiogenesis[13]. During the earliest stages of cardiac development ANF and MLC-1A genes are co-expressed in both atria and ventricles but at later stages they are restricted to atria only[18,20]. These atrial genes accomplish their regional specificity through their negative regulation in the non-expressing ventricular region[21]. Ventricular MLC-1 gene is co-expressed in all cardiac chambers in the early embryonic heart, and then is selectively down-regulated in the atrium during the later developmental stages. Analysis of day 8 murine embryo shows that MLC-2 gene is expressed exclusively in the ventricular region of the heart tube, suggesting that ventricular specification of heart occurs at the earliest stages of cardiogenesis[22-24].

In addition to the development of atrial and ventricular chambers, cardiogenesis also leads to the development of valvular structures derived from endocardial cushions, and differentiation of highly specialized pacemaker from the conduction system. Limited information is currently available regarding the pathways that regulate gene expression in these specific cardiac cells. In endocardial cushion, β-transforming growth factor[25] and a specific isoform of the fibroblast growth factor receptor are co-expressed[26]. Recent studies have documented the expression of 'Id' a negative helix–loop–helix regulator, in the growing endocardial cushions[27]. The expression of these genes in the subsequent development of valvular structures and septation events is still obscure. Neural genes, such as neurofilament-I perhaps expresses them into SA and AV nodal cells[28], and it suggests that the conduction system may either be derived or influenced by the neural crest during cardiogenesis[29]. Identification of the positional and molecular clues of gene expression in developing heart will enable us to understand the mechanism of malformations of cardiac structures.

Around birth important switches in gene expression such as postnatal changes in contractile proteins start operating[30,31]. During the fetal development β-MHC is the most abundant isoform, but α-MHC abruptly increases following birth and remains as a predominant isoform during the adult stage. The induction of α-MHC coincides with increase in circulating thyroid hormone after birth[31,32]. Alterations in the thyroid status have been shown to be important for the postnatal protein isoform switching[33]. Promoter region of α-MHC gene contains a binding site for thyroid hormone[34,35]. Binding of thyroid hormone to this nuclear receptor induces a conformational change and ensues the binding of this complex to its DNA binding-site. This DNA sequence is specifically responsible for thyroid hormone responsiveness to a heterologous gene. The catalytic α-subunit of Na^+/K^+-ATPase is also subjected to isoform switching (from α_3 to α_2) during postnatal development. Developmental or physiological stimuli, other than thyroid hormone, regulate Na^+/K^+-ATPase isoform gene expression[33,36]. Another prominent feature of developing heart is the overall increase in metabolic capacity and the shift from carbohydrate to fatty acid utilization[37] and selective upregulation of mRNA encoding enzymes involved in fatty acid metabolism and oxidation[38,39].

The most striking feature of the postnatal cardiac development is the loss of the proliferative capacity of cardiac myocytes[40]. In this respect, a marked distinction can be made between skeletal and cardiac muscle cell development. Muscle specific contractile protein isoforms are expressed only after cell cycle withdrawal in skeletal muscle cell lineage. On the other hand fetal cardiomyocytes express muscle markers during cell proliferation[41]. Furthermore, in response to an increase in workload skeletal muscle is able to recruit precursor cells (satellite cells), whereas heart responds solely by increasing the volume of pre-existing cardiomyocytes. Although, MyoD[42–44], Rb gene[44], Id gene[33], proto-oncogenes and peptide growth factors[45], have been recently implicated to arrest cell cycle in terminally differentiated cardiomyocytes, the exact molecular mechanism is still a major challenge to modern biology.

Cardiac contractile protein genes

The sarcomere is the basic contractile unit of the myocardium[46]. The contractile properties of the myocardium in terms of force generated and velocity of contraction are dependent on the number as well as the biochemical composition of its sarcomeres. The sarcomere is made up of seven major and several minor proteins organized into thick and thin filaments (Table 1). The thin filaments are formed by a double helix of polymerized sarcomeric actin molecules. In the major groove of this double helix, a continuous coil of tropomyosin (Tm) dimers are located (Figure 1). Every tropomyosin dimer interacts with seven actins and it is associated with a troponin (Tn) complex. Each complex in turn is composed of one molecule of each of the three troponins – T, C and I. This tropomyosin–troponin complex regulates calcium sensitivity of the apparatus and interaction between the heads of the myosin molecule, located in the thick filament and actin. The thick filament contains a bifunctional molecule of MHC which consists of rod portion and head portion. The rod portion carries the load during contraction and head portion interacts with actin and carries ATPase activity for fibre shortening. The ATPase activity is modulated by the alkali and regulatory MLC. Fibers with a high ATPase MHC activity contract faster than those with a lower enzymatic activity[47,48]. Thus, the type of MHC and its ATPase activity present in the sarcomeres are physiologically significant.

Table 1. Expression of multiple isoforms of cardiac contractile protein genes

Family	Embryonic isoforms	Adult isoforms	
		Ventricle	Atria
Actin	α-Skeletal α-Cardiac α-Smooth	α-Cardiac	α-Cardiac
Myosin heavy ch.	α-MHC β-MHC	α-MHC	α-MHC
Alkali MLC	MLC-$1_{A\&v}$ MLC-3	$MLCI_v$	$MLCI_A$
Regulatory MLC	MLC-$2_{A\&v}$	MLC-2_v	MLC-2_A
Troponin T	Tn-T_c	Tn-T_A	Tn-T_c
Troponin C	Tn-C_c	TN-C_c	Tn-C_c
Troponin I	Tn-I_{sc}	TN-I_{sc}	Tn-I_{sc}
Tropomyosin	α-Tm β-Tm	α-Tm	α-Tm
Creatine Kinase	CK-BB CK-MM	CK-MM	

MHC, Myosin heavy chain; MLC, Myosin light chain; Tm, Tropomyosin; Tn, Troponin. The subscripts cardiac (c), slow cardiac (sc), ventricular (v), atrial (A) indicate the tissue and or developmental stages in which the gene product is predominantly expressed. Creatine Kinase B and M isoform indicate the muscle-specific (M) and non-muscle (B) isoforms. (Reproduced from Reddy *et al.*, *Indian J. Pharmacol.*, 1996, **28**, 58–71).

The regulated expression of cell type-specific protein isoforms that are structurally distinct and developmentally regulated is a prominent feature of the myocardium. Most of the contractile protein genes that are expressed in the heart[46,49,50] have multiple isoforms (Table 1). Moreover ventricular and conduction system isoforms of the same protein differ from each other[51]. The developmental regulation of isoform expression in embryonic and adult stage is well orchestrated[52]. The physiological advantage of selective isoform distribution is not yet clear.

Regulation of cardiac specific gene expression

Evolution has provided the cardiovascular system with several strategies for the acquisition of tissue-specific phenotypes. Many contractile proteins are encoded by small multigene families whose differential expression in ventricular, atrial and conduction system distinguishes one type of myogenic tissue from the other[53,54]. Understanding of molecular mechanisms that control the cardiac

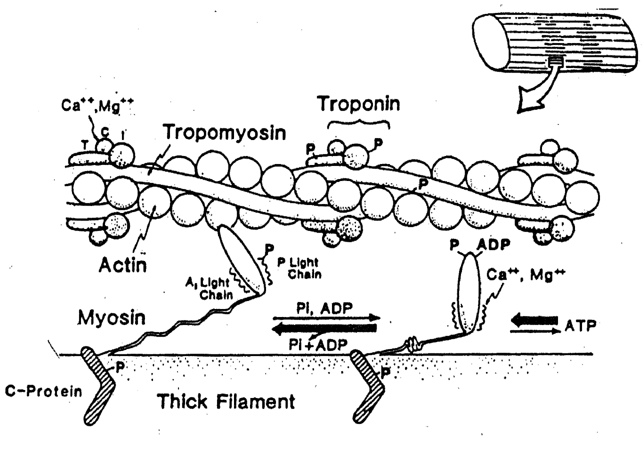

Figure 1. Ultrastructural organization of a sarcomere of cardiac muscle.

muscle specific gene expression is just a beginning, in spite of the limitation afforded by the adult cardiac myocyte with respect to its inability to proliferate and maintain its differentiated phenotype in culture[13]. Moreover, the similarities in morphology and biochemistry of cardiac and skeletal muscle give an idea that tissue-specific expression in these two striated muscle types might follow similar paradigm[41,55].

In recent years complementary DNA (cDNA) and genes encoding many of the contractile elements that are important for the developmental regulation of these genes has revealed the contribution of both transcriptional and post-transcriptional processes for their expression. The nuclei are induced to produce their own muscle regulatory factors which in turn contribute to the modulation of expression of the muscle genes[56]. These protein factors, which are involved in muscle differentiation, are called '*trans*-acting factors', which may be either positive or negative regulatory types[57,58]. Hence, *trans*-acting factors can serve as developmental switches to turn specific genes 'on' or 'off' at appropriate locations and at different times during cardiac development. DNA sequence analysis of muscle-specific genes has allowed the recognition of some sequences of regulatory region important in gene transcriptional regulation. These DNA elements are named as '*cis*-acting sequences' because they are located on the same molecule of DNA as the gene being regulated[59-61]. Some of the *cis*-acting sequences equipped for the high level tissue-specific expression of the cardiac contractile protein genes which utilizes a variety of paradigms for the regulation of gene expression are listed in Table 2.

Recent development of transgenic, transfection and microinjection techniques enabled us to characterize the molecular pathways that control the transcription of muscle genes during cardiac development. Two molecular paradigms for the control of cardiac muscle-specific expression have been recently elucidated[61-68]. Creatine kinase, cardiac and skeletal alpha-actin genes showed E-box-dependent[41,67], and MLC-2, Troponin T,C and MHC genes demonstrated E-box-independent pathways[23,66,68].

Table 2. The *trans*-acting factors and *cis*-acting elements involved in regulation of cardiac muscle specific gene transcription

Trans-acting factor	*Cis*-acting sequence	Gene
MyoD family (ref. 62)	E-Box	α-card. actin α-sk. actin

Id (ref. 66)	E-Box (-)	α-card. actin α-sk. actin

E-box dependent pathways

Recent studies of skeletal myogenes have uncovered a number of master transcriptional factors that can dominantly specify the differentiated muscle cell phenotype following their expression in permissive cell types[69-74]. The identification of a host of myogenic determination genes (*MyoD*; *myf-5*; *myf-6/MRF-4/herculin*), has led to a wealth of information on the mechanisms that regulate muscle genes during skeletal myogenesis. MyoD and its family members are expressed both in skeletal and cardiac muscles[41]. The characteristic feature of these transcription factors is that when injected, they can convert fibroblasts into myoblasts[58].

These proteins share a common structural motif, referred to as the basic helix–loop–helix (bHLH) region. The bHLH motif consists of two highly conserved alpha-helices connected by a more variable loop region (Figure 2). This HLH region is preceded by a region which is involved in DNA binding[75]. To activate the muscle gene programme these muscle-specific proteins form heterodimers with other bHLH proteins through interaction of their HLH regions[63,76]. Ubiquitously expressed bHLH proteins E12 and E47, which are splice variants of the E2 gene, provide functionally important dimerization partners of the *MyoD*-like bHLH proteins[76,77]. The *MyoD/E12* heterodimer has a high affinity for the DNA sequence CANNTG (also called E-box site), which is present in the regulatory regions of many muscle-specific genes[77]. The binding of the *MyoD/E12* heterodimer to the E-box site will upregulate the transcription of proteins like muscle creatine kinase[78], MLC-1[79] and cardiac alpha-actin[67]. Another ubiquitously expressed HLH protein, known as Id (inhibitor of differentiation) is also able to interact with *MyoD*. However, this protein lacks the basic DNA-binding region[66], therefore, interaction between *MyoD* and *Id* prevents the formation of a functional heterodimer which can bind to the E-box site. Consequently, activation of muscle-specific genes depends on the cellular levels of *MyoD*, *E12* and *Id*. High level of *Id* prevents the formation of functional *MyoD/E12* heterodimer complexes. Overexpression of Id down-regulates transcription from both skeletal and cardiac alpha-actin promoter–reporter constructs in myocytes[80] and mutation in E-box sites negatively affect the expression of genes[67]. The role of E-box-dependent pathways in the control of cardiac gene programme is still not settled.

E-box independent pathways

Recent studies have led to the characterization of the *cis*-regulatory elements and their corresponding factors, which are components of the E-box-independent pathways for cardiac muscle-specific expression[41]. This A + T rich DNA sequences have been found in the promoter/enhancer regions of various muscle genes such as creatine kinase[81], cardiac troponin T (ref. 65), and MLC-2 (refs 22, 82). Sequence comparison of rat MLC-2 promoter revealed three highly conserved regions (*HF-1*, *HF-2*, *HF-3*) within the first 250 base pairs of the promoter[82]. Transient transfection studies have shown that this region was sufficient to confer cardiac-specific expression. Transgenic studies[83], gel mobility shift assays and methylation interference analysis[22] demonstrated that two nuclear proteins specifically bind to the *HF-1* site. One designated as HF-1a is found to bind the core region of the 28 base pair of *HF-1* element (Figure 2). The second, HF-1b binds to an A + T-rich region which is homologous to the so-called myocyte enhancer factor-2 (*MEF-2*) binding site in the muscle creatine kinase enhancer[23]. Transient transfection assays have indicated that both HF-1a and HF-1b binding regions are required for transcriptional activity in cardiac muscle cells. Recently, a HF-1b binding protein factor is isolated from a cDNA library from neonatal rat hearts[24] and it represents a novel zinc finger protein with homology to *SP-1* (Figure 2). HF-1b is expressed in both skeletal and cardiac muscles. Unlike E-box sites, A+T rich sites have been shown to be important in the regulation of gene transcriptions in myocardium[54]. The elucidation of the precise molecular mechanisms that control cardiac specific gene expression will depend upon the cloning, characterization and functional analysis of factors which confer tissue specificity.

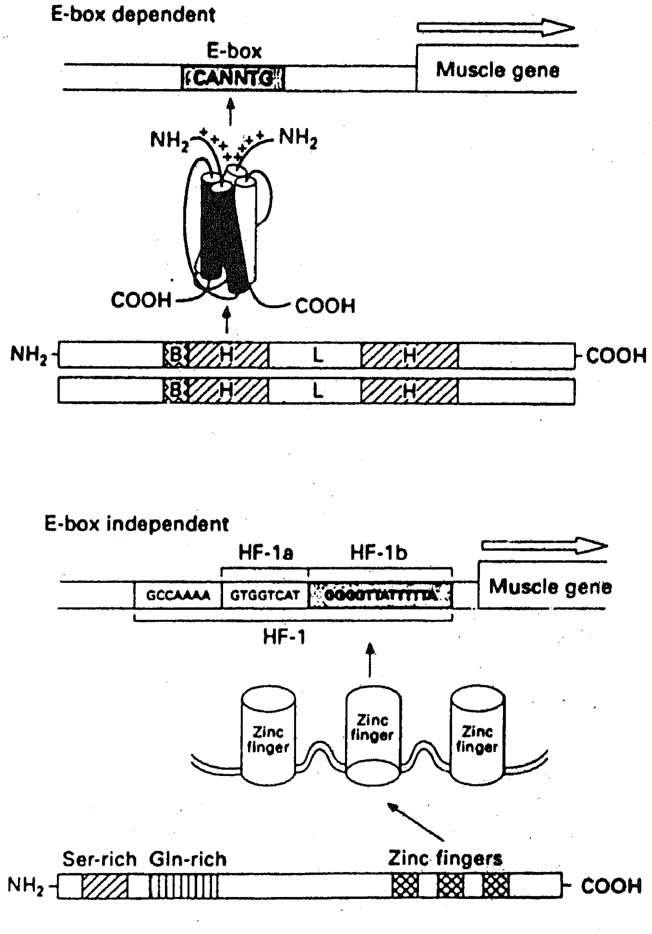

Figure 2. The *trans*-acting factors and *cis*-acting elements involved in E-box dependent and E-box independent regulation of cardiac muscle gene transcription[13].

Pathobiology of cardiac hypertrophy

It is now apparent that hypertrophy of the overloaded heart is a complex process that is both beneficial to compensate the overload, and detrimental because the hypertrophied cells are not normal[84]. Since the myocytes are terminally differentiated and lose their ability to proliferate soon after birth, they respond to increase in workload by an increase in cell size (hypertrophy), and not by an increase in cell number (hyperplasia). Chronic increase in wall tension lead to left ventricular hypertrophy, ventricular dysfunction (Figure 3) and ultimately

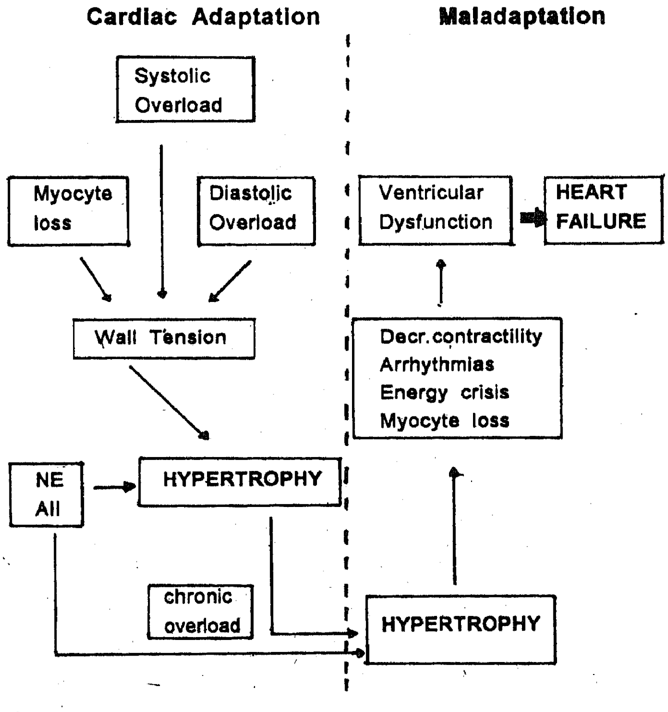

Figure 3. Postulated pathophysiological scheme of cardiac hypertrophy and failure.

decompensated hypertrophic heart failure if adequate measures are not taken[85]. The extent of hypertrophy is also modulated by the release of autocrine or paracrine factors such as norepinephrine, angiotensin-II, and peptide growth factors. In various models of cardiac hypertrophy, systolic and diastolic wall stress have been implicated as the major determinants of the degree and patterns of hypertrophy during pressure and volume overload[86].

Morphological changes

The structural and functional abnormalities of the hypertrophied myocardium have been examined in depth. An increase in the load against which the heart ejects, gives rise to adaptive changes in the heart which vary with the species studied and severity of the overload. The myocytes become bigger, contract and relax more slowly as a consequence of an adaptive mechanism[87]. In addition, ventricles become stiff and premature beats are more frequent[84]. Increase in cardiocyte size[88] and interstitial connective tissue[89,90] may be responsible for the stiffness of hypertrophied myocardium. The walls of the heart grow thick initially in response to overload[91], but become thin in end-stage of decompensated hypertrophy. Myocyte necrosis stimulates proliferation of the fibroblasts replacing myocardial cells with connective tissue[92]. Progressive overload on the surviving cells of the hypertrophied heart, relative decrease in capillary density and number of mitochondria probably contribute to a chronic energy deficit. The growth of the coronary vascular may not commensurate with increased cardiac mass and work load accompanying cardiac hypertrophy[93] especially in the subendocardial layer[94] and may thus lead to episodic underperfusion and myocardial damage. Alterations in muscle chamber compliance during hypertrophy have been identified as a result of potential decrease in contractile function[86]. Increased capacity for and efficiency of protein synthesis may account for rapid cardiac growth[95,96] and change in gene programme may lead to variations in electrophysiological and biochemical properties of hypertrophied heart.

Electrophysiological changes

Action potential duration (APD) is prolonged in isolated multicellular[97,98] and single cell preparations of hypertrophied hearts[99,100]. Such a change may be compensatory response to ensure maximal contraction by slowing V-max, but it impairs cardiac relaxation via myoplasmic calcium overload[101]. Prolonged APD may thus be linked to the contractile abnormalities found in hypertrophy[102] and high incidence of arrhythmias. An increase in cell capacitance consequent to enhanced surface area of myocytes does not account for the observed prolongation of APD. Changes in the current-carrying system of the sarcolemma may explain the noted increase in APD. Increased APD may contribute towards the increase in contractile strength and cardiac output of hypertrophied heart[103].

Biochemical changes

The rate of energy utilization is abnormally increased in acute pressure overload hypertrophy[104], resulting in energy crisis. The myosin ATPase activity, associated with energy utilization is decreased as a result of an isoenzymatic shift from V_1-(high ATPase activity) to the V_3-(low ATPase activity) of myosin[105]. This adaptation may exercise economy in the use of energy in hypertrophied myocardium. β_1-Adrenergic receptors are down-regulated in spite of normal noradrenaline levels[106], but α_1-adrenergic receptor population markedly increased in cardiac hypertrophy[107]. Cholinergic muscarinic receptors are also found down-regulated. The increase in calcium channel number[108], decrease in activity of Na^+/Ca^{2+}-exchanger[109], α-subunit isoform shift of Na^+/K^+-ATPase (ref. 110), diminished function of Ca^{2+}-ATPase of sarcoplasmic reticulum[111], and down regulation of β_1-adrenergic receptors are postulated to lead to disturbance in calcium homeostasis and ventricular arrhythmias.

Gene expression changes in hypertrophied myocardium

Application of recombinant DNA technologies and cellular biological methods during the last 10 years to cardiac myocytes enabled us to understand that the cardiac phenotype changes with ontogeny, aging and hypertrophy[50]. The ability of the heart to alter its protein composition is a tonic control mechanism of cardiac function. The heart first responds to increased workload by altered function, followed by gene expression and increased muscle mass. Hemodynamic overload produces a complex pattern of gene programming characterized by changes in protein isoform switches and quantitative alteration in individual gene expression in the myocyte[50,112].

Recently, many genes responsive to increased workload have been identified and are divided into two classes[10]: one designated as immediate early genes (IEG), and the second, late response genes (LRG). IEGs are a group of proto-oncogenes whose transcription is activated rapidly and transiently by extracellular stimulation[113-116]. The transcriptional induction is not dependent on new protein synthesis, but subsequent shut-off of transcription requires new protein synthesis[117,118]. The expression of LRG is induced more slowly, over hours, and also needs new protein synthesis. LRG expression includes, upregulation of constitutively expressed cardiac contractile protein genes and re-expression of fetal-type genes.

Expression of proto-oncogenes

One of the early responses of cardiac cells to overload is the induction of a series of proto-oncogenes[115], that directly or indirectly turn on the cascade of events leading to hypertrophy. Proto-oncogenes owe their name to the fact that they are cellular counterparts of viral oncogenes and altered genes of neoplastic cells[118]. However, recently it has become clear that proto- oncogenes or cellular oncogenes (*c-onc*) are bonafide transcriptional factors which participate in normal growth induction of the cell in response to growth stimuli[119]. Many proto-oncogenes control the re-entry of resting cells (G_0 phase) into the cell division and regulate the transcription of a variety of genes. Proto-oncogenes exert their regulatory effects by encoding a variety of growth factors and their receptors, intracellular transducers, modulators, amplifiers, and DNA-binding factors involved in the control of RNA transcription[120,121]. Approximately 100 IEGs have been identified so far[10]. Several proto-oncogenes of the *fos* family such as *c-fos, fra-1 fos-B* (refs 122–124), *jun* family such as *c-jun, jun B, jun D* (refs 125, 126), *c-myc* (ref. 127), *Egr-1* family such as *krox 24, NGF1-A* (refs 128–131), and *nur/77* or *NGF1-B* (refs 128, 132) have been characterized.

Proto-oncogenes such as *c-fos* and *c-myc* are induced *in vivo* and *in vitro* rat heart models[115,133-136]. The expression levels of proto-oncogenes is proportional to the magnitude of coronary flow, coronary pressure and systolic wall stress[137]. Stretching of myocytes by *in vitro* model[116,138–140] stimulates the expression of *c-fos*, *c-myc*, *c-jun* and *Egr-1*, in a stretch length-dependent manner followed by increase in protein synthesis. Hemodynamic overload increases the expression of *c-fos* and *c-myc* proto-oncogenes that encode short-lived nuclear proteins that promote and regulate cell proliferation and differentiation[115,120,141,142]. The activation of these proto-oncogenes may be an adaptive response to stress. The induction of *c-fos* and *c-myc* which occurs within an hour of acute pressure overload, is transient and precedes the expression of fetal isoforms of several contractile protein genes[115].

Recent studies revealed that the protein products of *c-fos* and *c-jun* interact with each other to form a heterodimeric transcription factor complex through a conserved dimerization motif referred to as leucine zipper[143]. The leucine zipper domain is an alpha-helical structure composed of leucine residues spaced seven amino acids apart and promotes dimerization. The *c-fos/c-jun* heterodimer binds with high affinity and specificity to DNA elements of the consensus sequence called TRE. TRE is first identified as phorbal ester-inducible promoter element and is a binding site for transcription factor *AP-1* (refs 102, 144), *c-fos* and *c-jun* are major constituents of *AP-11* (ref. 145). The expression of *c-fos* and *c-jun* is induced rapidly by a number of external stimuli and consequently *c-fos/c-jun* complex induces the expression of LRG containing *AP-1* sites[146]. *c-fos/c- jun* complexes transactivate a number of genes containing *AP-1* sites, where *c-fos/jun B* complexes repress them under certain circumstances[147]. IEGs also have a regulatory function in post-mitotic cells[113].

The mechanisms by which proto-oncogenes are induced are best characterized by studies of *c-fos*. *c-fos* is induced by multiple intracellular second messengers acting through distinct upstream regulating elements. Transcriptional activation by PKC is mediated by serum response element (SRE) located 300 bp upstream of the mRNA initiation site. The SRE consists of 20 bp dyad symmetric sequence and is a specific binding site for dimeric SRF and other associated factors such as *SAP-1* (refs 148, 149). *c-fos* stimulation by cAMP and Ca^{2+} is dependent on Ca^{2+}/cAMP regulatory element (CRE) located 60 bp upstream of the mRNA start site. The Ca^{2+}/CRE is an 8 bp palindromic sequence and is a specific binding site for the dimeric transcription factor (CREB). The increase in intracellular cAMP and Ca^{2+} activates protein kinase A and Ca^{2+}/calmodulin kinase, respectively, and these kinases phosporylate CREB at a specific residue (ser-133) in order to activate it as a transcription factor[150].

Cellular proliferation and differentiation is regulated by *c-myc* (ref. 151). Increased expression of *c-myc* results in an increase in the rate of proliferation and prevents differentiation[152,153]. Inhibition of *c-myc* expression by antisense strategy inhibits proliferation and initiates differentiation of variety of cell types[154]. *c-myc*, as a transcription factor induces a family of heat shock proteins[155]. Recently, *Max* a partner of *c-myc* in forming a heterodimer complex has been isolated, and the transcriptional functions of *c-myc* have been further elucidated[156]. *Egr-1* is also isolated as IEG to growth factors. Atrial natriuretic factor[157] and transforming growth factor-β[158] have *TRE/AP-1* binding sites in the promoter regions and may become targets of these proto-oncogenes. Recently using co-transfection assays it has been shown that *c-jun* or *c-jun/c-fos* transactivate human skeletal alpha-actin gene expression, suggesting that skeletal alpha-actin may be regulated by *c-fos/c-jun* complex in addition to *AP-1/TRE* mechanisms. Other transcriptional mechanisms activated by the *c-fos\c-jun* complex may also be present[159]. *c-myc* is abundantly expressed in the heart during the fetal period; however its expression becomes undetectable soon after birth[115]. Elevated *c-myc* mRNA expression stimulates hyperplastic myocyte growth, but it does not induce cell hypertrophy and alterations of terminal differentiation[160]. *Egr-1* is induced by hemodynamic overload, alpha-adrenergic receptor stimulation and stretch of myocyte[161]. It has a zinc finger DNA-binding motif and the ability to transactivate other genes which have the target sequence C G C C C C G C (ref. 162). *Egr-1* may also transactivate some cardiac genes such as alpha-MHC as a result mechanical stress[163].

Different stimuli induce the expression of slightly different panels of proto-oncogenes, and are associated with different hypertrophic phenotypes of the cardiomyocyte. Pressure overload leads to a form of hypertrophy that is characterized by a reduction in sarcoplasmic reticular Ca^{2+}-ATPase activity[164–166] and a shift from α-MHC to β-MHC isoform expression. In contrast, thyroid hormone induces a different form of hypertrophy that is associated with increased Ca^{2+}-ATPase activity[165,167] and enhanced α-MHC isoform expression. Stimulation with α- and β-adrenergic receptor agonists is also associated with different expression of IEGs[161]. These evidences suggest that proto-oncogenes might control the expression of late response genes as nuclear mediators that couple external stimuli to long-term changes in gene expression.

Re-expression of the fetal isogenes

The major contractile proteins of the heart have multiple isoforms (Table 1). Tropomyosin, Tn-T and MLC isoforms are generated by alternative pre-mRNA splicing[168], and isoforms of MHC, MLC, actin, tropomyosin, Tn-T, Tn-I and Tn-C are produced by a multigene family[46]. The expression of each member of this multigene family is regulated tissue specifically at the transcriptional level. In cardiac hypertrophy, the contractile protein genes are selectively activated either by pre-mRNA splicing[141] or at transcriptional level[169,170]. Gene phenotypes of contractile proteins such as skeletal alpha-actin[171], MLC-1 (ref. 172), tropomyosin[141] and troponins[173,174], membrane proteins such as Na^+/K^+-ATPase[175–177], and those involved in ATP regeneration such as creatine kinase[178] are induced in cardiac hypertrophy. Most of these protein isoforms are normally expressed only during fetal and early post-natal life (Table 3).

Myosin heavy chain (MHC), a late response fetal gene is investigated at the physiological and molecular levels[105]. In the ventricles of most mammalian species three myosin isoforms have been identified on the basis of electrophoretic mobility – V_1, V_2, V_3 (ref. 179). However, these three myosins are composed of only two distinct types of MHCs, referred as alpha and beta. V_1 and V_3 are composed of alpha–alpha and beta–beta homodimers, respectively, while V_2 is an alpha–beta heterodimer. These two myosins are produced by two different genes[180]. The relative distribution of α- and β-MHC is directly correlated with the contractile properties of the heart. The α-MHC, which has high Ca^{2+} and actin-activated ATPase activity, is associated with an increased muscle-shortening velocity. In contrast, the β-MHC, which has lower ATPase activity is associated with slower shortening velocity[47,105].

Pressure overload hypertrophy induces a qualitative change in myosin composition from alpha-(V_1) to beta-(V_3)-isoform[164]. This alteration in myosin composition is largely due to down regulation of the alpha-MHC gene and concomitant re-activation of β-MHC gene expression[32]. The reactivation of β-MHC gene is one of the first well-characterized molecular markers for the activation of an embryonic gene programme during myocardial hypertrophy[181,182]. The change from α-MHC to β-MHC results in slower rate of ATP cycling by myosin which accounts for slower velocity of contraction of hypertrophied heart[183]. However the tension generated during each systole is increased which facilitates ejection by the overloaded heart. Furthermore, sliding of actin and myosin filaments slows down, leading to minimal energy consumption. This sequence of events is considered to be an adaptive response of heart to the mechanical overload. The *cis*-regulatory elements and corresponding *trans*-acting factors mediate the up-regulation of the beta-MHC genes during hypertrophy[184,185]. Kariya *et al.*[135,136] have localized an α_1-adrenergic responsive fragment within the β-MHC promoter region that mediates expression to α-adrenergic stimulation in myocardial cell hypertrophy. Ventricular hypertrophy in larger animals and humans is not associated with the induction of either β-MHC or actin genes, which are constitutively expressed in large animals[182,184]. However in human atria, change of α-MHC to β-MHC is readily apparent in response to increased pressure overload[186]. In contrast,

Table 3. Phenotypic changes in myocardial ventricular proteins during cardiac hypertrophy

	Fetal	Adult	Hypertrophy
MHC	β-MHC α-MHC	α-MHC	β-MHC
α-Actin	skeletal cardiac	cardiac	cardiac
MLC-1	MLC-1_v MLC-1_A	MLC-1_v	MLC-1_v MLC-1_A
MLC-2	MLC-2_{v+}	MLC-2_{v+}	MLC-2_{v+}

(Reproduced from Reddy *et al.*, *Indian J. Pharmacol.*, 1996, **28**, 58–71.)

a marked increase in the skeletal α-actin mRNA has been reported in a diseased human heart[187].

Skeletal α-actin gene, another marker of the embryonic gene programme, is uniformly induced throughout the ventricles[188]. The *cis*-regulatory elements and corresponding *trans*-acting factors that mediate upregulation of skeletal α-actin[189] and smooth muscle actin[170] during the hypertrophy are incompletely characterized. The genes encoding MHC isoforms are regulated in an antithetical manner in early stages of hemodynamic overloads, whereas hemodynamic overload up-regulates skeletal alpha-actin gene but does not affect the cardiac alpha-actin[190]. Thus the different sarcomeric components in the same heart are not equivalent targets for the mechanisms activated by changes in external cardiac load in hypertrophy. A 67 bp fragment in skeletal actin gene conferred myocyte specificity and inducible ability by alpha-1-adrenoceptor stimulation[191]. It contains a CArG box, SP1 and M-CAT sequences. Knowlton *et al.*[192] determined *cis*-elements that mediate alpha-adrenergic expression within 315 bp sequence of ANF (*CRE*, *AP-2*, *AP-1*, *Egr-1*, CArG) and 92 bp of MLC-2 (*AP-1*, *CArG*, *MEF-2*, *AP-2*) gene.

ANF is expressed in the ventricle as well as in the atrium during embryonic development but after birth the expression of ANF is restricted to the atrium. However being a potent vasodilator and natriuretic agent, ANF is abundantly re-expressed in ventricles subjected to overload in order to reduce wall stress[177]. ANF gene is utilized as a marker for embryonic gene programme during hypertrophy[15]. A variety of hypertrophic stimuli induces ANF gene in ventricular muscle cells[61] and therefore is a useful genetic marker of cardiac hypertrophy. Regional-specific expression of ANF in the atria[193] is clearly segregated from those that are responsible for inducibility[194]. Recent studies have mapped the inducible regulatory elements in the rat ANF gene to a proximal region of ANF promoter that lacks consensus *Egr-1*, *CRE*, *AP-1*, *CArG* element. ANF gene expression is regulated by a variety of stimuli such as hormones[177,195], and physical stretch of myocardial tissue[176]. Activation of PKC induces secretion of ANF as well as expression of ANF gene[196]. PKC activates the *c-fos* and *c-jun* genes. *c-fos/c-jun* complex interacts with *AP-1* binding sites and activates the ANF gene expression suggesting the potential role of proto-oncogenes in ANF gene expression in hypertrophy.

Genes encoding Ca^{2+}-ATPase of the sarcoplasmic reticulum are altered by hemodynamic overload[197]. The mRNA level of Ca^{2+}-ATPase decreases gradually in pressure overload[165,198] and expression levels are reduced in the failing human heart[166]. The decrease in the Ca^{2+}-ATPase protein may be accounted for the abnormal calcium handling in the hypertrophic and failing hearts.

Induction of constitutive gene programme

In addition to qualitative alterations in the cardiac muscle gene programme, there are quantitative alterations in the expression of constitutively expressed contractile protein genes that lead to characteristic accumulation of contractile proteins and sarcomeric units in individual cardiac muscle cells. MLC-2 gene investigated extensively[22,192,199] was found up regulated. Recent studies in both cultured myocardial cell models[192] and pressure overload transgenic mice which harbour a 250 bp MLC-2 luciferase fusion gene[83] revealed that the 250 bp fragment which confers cardiac-specific expression is also sufficient for inducible expression. Mapping studies of the MLC-2 gene documented an important role for the *HF-1* for cardiac specific and inducible expression to heterologous promoters[22]. The recent development of an *in vivo* murine model of cardiac hypertrophy[200] that can be used in transgenic approaches in myocardial hypertrophy model systems[201–203] may enable us to characterize genetic markers and novel factors of gene expression in hypertrophy.

Role of humoral factors and signalling mechanisms

Although the phenomenon of cardiac hypertrophy has been extensively investigated, the mechanisms that initiate cardiac cellular growth, change in myocardial gene expression in response to work overload and cellular signalling melecules remain incompletely understood. The development of cytoplasmic injection of neutralizing antibodies[204] and purified recombinant proteins as well as nuclear injection of expression vectors in contracting cardiac muscle cells[203] has provided a valuable tool to distinguish between cellular signalling messengers from hypertrophic phenotype markers. Recent studies on hypertrophic phenotype markers in cultured myocardial cell model[205], enabled us to unfold the potential cellular signalling pathways responsible for cardiac growth and hypertrophy (see Figure 8).

Mechanical stretch

Mechanical stretch of the ventricular wall is associated with increased protein synthesis[206,207] and activation of a number of hypertrophic markers[208–214]. Effect of ventricular stretch on growth is a cAMP dependent mechanism[215]. Myocyte stretching stimulates expression of proto-oncogenes, followed by expression of fetal genes[116,138–140]. Stretch-activated ion channels have been proposed as the transduction mechanism between load and protein synthesis in cardiac hypertrophy[216]. Stretch-sensitive channels which allow the passage of physiological cations, such as Na^+ and K^+, and Ca^{2+} are implicated[216-218]. Na^+ influx is demonstrated to increase protein synthesis in heart. However Na^+ ionophores such as monensin and veratridine did not reduce fetal type gene expression in cultured cardiomyocytes[218]. Cardiomyocytes, endothelial cells, fibroblasts and smooth muscle cells may secrete some hypertrophy-promoting factors following a stretch stimulus.

Myotrophin and peptide factors

A cardiac hypertrophy-related factor 'myotrophin' has been demonstrated to exist in the hypertrophied myocardium of spontaneously hypertensive rats[219]. It has been purified[219] and its nature and physiological roles are being explored. Myotrophin stimulates protein synthesis *in vitro* in both neonatal and adult cardiac myocytes[219], and it has also been shown that incubation of neonatal rat cardiac myocytes with 'myotrophin' for 30 min induces proto-oncogenes like *c-myc*, *c-fos* and *c-jun* analogous to the pressure overload- induced expression of proto-oncogenes. Further, increased accumulation of mRNA for ANF, β-MHC and skeletal α-actin have been observed in cardiomyocytes treated with this protein for 24 h (ref. 220), suggesting that the 'myotrophin' may be a pivotal modulator for myocardial cell growth and differentiation.

Numerous peptide factors have also been reported to be elevated in the plasma of patients with cardiac disorders. A 17.8 kDa hemo-protein has been demonstrated in the serum of patients with myocardial infarction[221]. Increased level of a hypertension associated protein of molecular weight 28 kDa has been observed in animals and humans with essential hypertension[222,223]. Presence of a 182 kDa protein has been found 6 h after the aortic constriction in animals, and persisted during the progression of hypertrophy and disappeared at late stages[224,225]. Multiple injections of polyclonal antibody raised against this protein into the aorta constricted animals totally abolished the development of cardiac hypertrophy and also suppressed the expression of β-MHC. Moreover, elevated levels of this peptide have been reported in patients with ventricular septal defect and aortic regurgitation further suggest that this peptide factor could play a role in the development of hypertrophy and the molecular mechanisms associated with cardiac hypertrophy[226,227].

Renin–angiotensin system

The renin–angiotensin system (RAS) is integrally involved in cardiovascular and renal homeostasis[228]. The principal mediator of the physiological actions of the RAS is the octapeptide angiotensin-II (A-II). Angiotensinogen, the precursor of A-II is hydrolysed by the enzyme renin, thus resulting in the formation of the decapeptide angiotensin-I (A-I). The two carboxyterminal amino acids of A-I are cleaved by angiotensin converting enzyme (ACE) to form the octapeptide A-II (ref. 229). A-II directly modulates cardiac functions such as myocardial contractility, metabolism and hypertrophic growth[10,230-232].

An increasing number of studies suggested the existence of local renin–angiotensin system in several organs such as the kidney, adrenal gland, brain, blood vessels and heart[3-5,233-236]. Much evidences support the existence, functional integration and physiopathological role of cardiac RAS[1,237-239]. Molecular biological and biochemical techniques clearly demonstrated local synthesis of mRNA of angiotensinogen, renin, and converting enzyme in the heart, indicating the presence of a physiologically active cardiac RAS. A-II has been suggested as an important hormonal mediator of cardiac hypertrophy[238]. It is one of the growing number of peptide hormones that has been implicated in the regulation of cellular growth[240] and hypertrophy[241]. The direct growth effects of A-II have been extensively characterized in vascular smooth muscle cells, where A-II has been shown to promote hypertrophy *in vitro*[242-244]. A-II also causes hyperplasia of aortic smooth muscle cells of spontaneously hypertensive rats and the renal arteriole of normal rats[245,246], suggesting that A-II directly or in combination with other growth factors may play an important role in the development of vascular hypertrophy and elevated arterial resistance in hypertension.

Several *in vivo* studies have suggested that A-II may also be a critical factor in mediating cardiac hypertrophy that is associated with hypertension[247,248]. ACE inhibitors prevent or decrease LVH in animals[249-251] and in humans[252,253]. Clinical studies[254] demonstrated that treatment with ACE inhibitors reduced mortality in patients with heart failure. The ameliorative effects of ACE inhibitors may be ascribed to either hemodynamic changes such as reduction of systemic vascular resistance and LVEDP or alterations of cardiac RAS. Chronic infusions of sub-pressor doses of A-II to rats produced ventricular hypertrophy[254]. In genetic model of hypertension, ACE inhibitor produced regression of cardiac hypertrophy while control of rise in blood pressure with sympatholytic agents or vasodilators demonstrated no such effect[247,251]. Nonhypotensive dose of ramipril prevented the increase of cardiac mass in rats with aortic banding[251]. In addition, enalapril completely prevented the LVH with no effect on cardiac afterload[241]. Beinlich *et al.*[255] have demonstrated that AT_1 receptors may be involved in growth of the newborn pig heart. Treatment of patients suffering from myocardial infarction with ACE inhibitors prevented cardiac dilatation[256]. These observations tentatively suggest, in addition to indirect effects of A-II mediated increase in blood pressure and vascular resistance, that A-II may be directly responsible for the hypertrophy of heart.

ACE inhibitors also prevented the development of age-dependent hypertrophy[257]. A recent meta-analysis of 109 studies showed that ACE inhibitors are more effective than β-blockers, calcium antagonists and diuretics in reducing the left ventricular mass of hypertensive patients[258]. Multivariate analysis of the results showed that the reversal of cardiac hypertrophy is indirectly related to the blockade of RAS[259]. Captopril prevents myocardial fibrosis, collagen accumulation and DNA synthesis in rats with renovascular hypertension[260] and in myocardial infarction[261]. It indicates that A-II may play a role in the structural remodelling of the cardiac interstitium. Moreover the process of interstitial remodelling may lead to LVH and subsequent heart failure[262]. Recently, Schorb *et al.*[263] have shown that A-II is mitogenic to neonatal rat cardiac fibroblasts. Non-myocytes such as cardiac fibroblasts have G-protein-linked AT_1 receptors that are coupled with proliferative growth[264,265] and A-II induced cardiac hypertrophy may be partly due to stimulated increases in nonmyocyte cellular growth. A-II increases protein synthesis, total RNA and *c-fos* mRNA in cultured cardiomyocytes[265,266]. Increased rate of protein synthesis is blocked by a specific AT_1 receptor antagonist[267]. These observations suggest that A-II may induce hypertrophy by enhancing gene expression.

AT_1 and AT_2 receptor expressions are upregulated in response to hypertrophic stimuli[264]. The increased number of A-II receptors may contribute to the growth of heart and hyperplasia of cardiac fibroblasts. A-II induces IEGs such as *c-fos*, *c-jun* and *Egr-1* in cardiac myocytes and nonmyocytes. A-II also induces the 'fetal' genes such as ANF and α-skeletal actin and upregulates the expression of growth factor genes such as TGF-β and angiotensinogen. Activation of multiple phospholipid derived second-messenger systems via the AT_1 receptors in cardiomyocytes[265,268] may play a critical role in A-II induced gene expression and subsequent hypertrophy. Increased cardiac ACE activity[269], upregulation of mRNA of ventricular angiotensinogen[241,270] and mRNA of ACE[269] have been described in association with pressure-overload cardiac hypertrophy. It suggests that cardiac RAS may be activated in cardiac hypertrophy.

Several lines of molecular and biochemical studies from our laboratory have suggested that cardiac RAS plays a pivotal role in the pathogenesis of ventricular hypertrophy[1-4]. Treatment with hypotensive dose (100 mg/kg), as well as non-hypotensive dose (1.5 mg/kg) of captopril, an ACE inhibitor (Figure 4), markedly prevented the development of LVH (Figure 5), LV remodelling and prevented the increase in total ventricular protein, RNA (Figure 6) and antithetical expression of myosin heavy chain isogenes (Figure 7) in cardiac pressure-overloaded rats[1]. However, treatment with hydralazine (15 mg/kg), a vasodilator, did not modulate the hypertrophic changes[1]. Thus, the prevention of the development of LVH and induction of β-MHC by non-hypotensive doses of captopril may be related to the blockade of intracardiac production of angiotensin-II rather than circulating system.

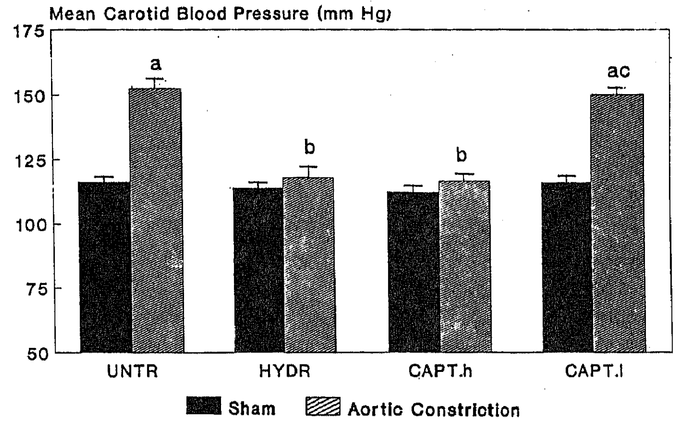

Figure 4. Effects of chronic treatment with captopril or hydralazine on mean carotid blood pressure in response to cardiac pressure overload induced by abdominal aortic constriction. Values are means ± S.E.m. $n = 5$–8 per group. Sham (filled bars); aortic constriction (hatched bars); UNTR, untreated; HYDR, hydralazine (15 mg/kg, p.o.); CAPT.h, captopril-high dose (100 mg/kg, p.o.); CAPT.l, captopril-low dose (1.5 mg/kg, p.o.), a $P < 0.05$ vs sham; b $P < 0.05$ for captopril/hydralazine treated vs untreated group; c $P < 0.05$ for captopril-aortic constriction-treated vs sham captopril-treated group. (Reproduced from Reddy *et al.*, *Mol. Cell. Biochem.*, 1996, **155**, 1–11.)

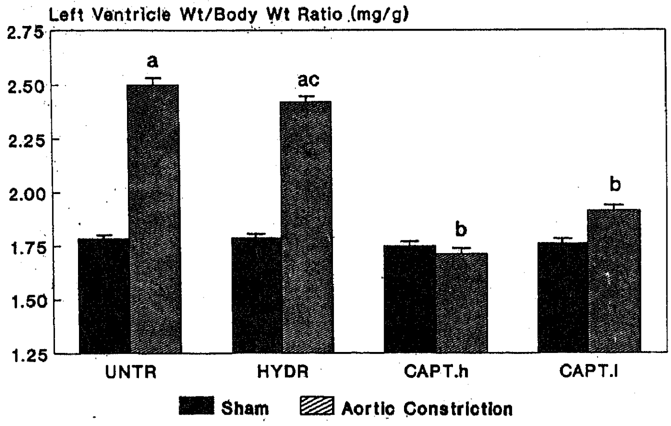

Figure 5. Effects of chronic treatment with captopril or hydralazine on left ventricular hypertrophy in response to cardiac pressure overload induced by abdominal aortic constriction. Values are means ± S.E.m. $n = 5$–8 per group. Sham (filled bars); aortic constriction (hatched bars); UNTR, untreated; HYDR, hydralazine (15 mg/kg, p.o.); CAPT.h, captopril-high dose (100 mg/kg, p.o.); CAPT.l, captopril-low dose (1.5 mg/kg, p.o.), a $P < 0.05$ vs sham; b $P < 0.05$ for captopril/hydralazine treated vs untreated group; c $P < 0.05$ for hydralazine-aortic constriction-treated vs sham hydralazine-treated group. Sympathetic nervous system

For long time, sympathetic nervous system activity has been implicated in development or modulation of cardiac hypertrophy[271,272]. *In vivo* studies also indicated that stimulation of either α- or β-adrenergic receptors leads to the development of myocardial hypertrophy independent of hemodynamic effects[273]. It has been demonstrated that α_1-adrenergic stimulation induces a hypertrophic response in both isolated adult myocytes[266] and neonatal myocytes. But β-adrenergic stimulation of isolated adult myocytes has a more general anabolic effect[107,274–279], and induces limited hypertrophic response. Alpha-1-adrenergic receptor stimulation increases diacyl glyceraldehyde (DAG) and protein kinase C (PKC) activity which may represent a link between receptor binding and accelerated transcription[203,280]. Administration of phorbol ester, a specific activator of PKC to the cultured myocytes leads to cellular hypertrophy[281]. Transient transfection of cells with plasmid encoding constitutive gene of PKC increases hypertrophic response[135,136]. PKC possibly affects gene transcription through phosphorylation of pre-existing transcription factors or through induction of novel transription factors (Figure 8)[282]. Expression of nuclear proto-oncogenes such as *c-fos* has been reported in response to nor-epinephrine[283] and isoproterenol- induced[284] cardiac hypertrophy.

Polypeptide growth factors

Recent studies, both *in vivo* and *in vitro* suggest that myocardium is the target of selected growth factors[285], and may play an important role in both normal and abnormal, such as hyperplastic and hypertrophic growth of heart[286]. The multifunctional polypeptide growth factors (PGF) may regulate the myocardial growth and differentiation. Two classes of growth factors, namely

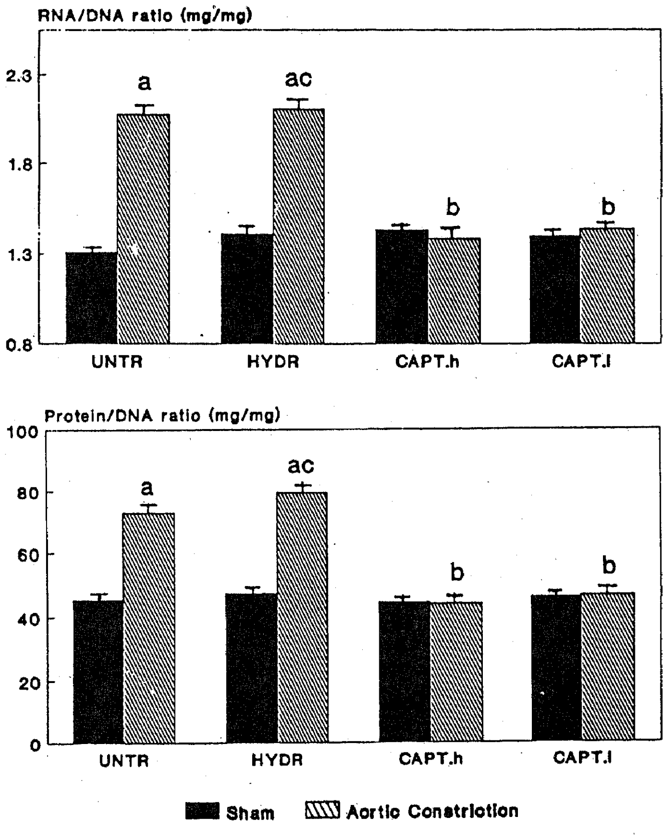

Figure 6. Effects of chronic treatment with captopril or hydralazine on RNA/DNA and protein/DNA ratios in response to cardiac pressure overload induced by abdominal aortic constriction. Values are means ± S.E.m. $n = 5$–8 per group. Figure 8. Diagrammatic representation of signal transduction pathways of stretch (ionic channels) α_1-, β_1-adrenergic and angiotensin-II (A-II) receptor-induced cardiomyocyte hypertrophy. (Reproduced from Reddy *et al.*, *Indian J. Pharmacol.*, 1996, **28**, 58–71.)

transforming and fibroblast growth factors (TGF and FGF) have been implicated in signalling processes in cardiac myocyte[287,288]. TGF-β induces re-expression of genes of the 'fetal' isoforms of MHC and actin[277] in normally developing and overloaded heart[289,290]. Growth factors such as α-FGF and TGF-β have been demonstrated to induce cardiomyocyte hypertrophy[291,292]. Insulin like growth factor-1 (IGF-I) induces hypertrophy with enhanced expression of muscle-specific genes in cultured cardiomyocytes[293] and elevated levels of IGF-I in acromegalic patients associates with cardiac hypertrophy[294].

Endothelins

Endothelin-1 (ET-1), a vascular derived peptide factor is another candidate to promote hypertrophy. ET-1 stimulates cardiocyte hypertrophy, sarcomere assembly, expression of proto-oncogenes and ANF. It also simultaneously increases phosphoinositol (PI) hydrolysis and consequent accumulation of IP_3 and DAG[295]. However, the exact role of ET-1 and the effect of mechanical stress on endothelin level are still obscure.

Molecular signalling transduction pathways

Intracellular signalling systems that are involved in cardiomyocyte growth and hypertrophy include oncogenic *H-ras*[296] and G-protein-linked hormone receptors[297] and their membrane enzymes including adenylyl cyclase and phospholipace C (PLC). cAMP induces the hypertrophy in cultured cardiac myocytes and increases the protein synthesis as well as ribosome formation[211,298]. Increase in PKA, PKC, and intracellular Ca^{2+} transduce signals by phosphorylation. These signals induce nuclear proto-oncogenes and transcription factors (Figure 8) which produce permanent changes in gene expression, leading to myocardial cell hypertrophy[228]. Stretch is the main trigger at the origin of the signal transduction, but several hormones such as NE and A-II may also play an important role. Furthermore, interactions between stretch and hormonal stimuli can potentiate each other and result in enhanced signal generation[299].

Recent studies showed that two distinct guanosine triphosphate-binding proteins, oncogenic *H-ras* and *Gq* mediate the hypertrophic response[236,297]. Furthermore, a dominant interfering *H-ras* mutant ablated the α-adrenergic induction of ANF expression[236]. The two G-proteins are part of the signalling pathway that couples the angiotensin and α-adrenergic receptor to the fetal gene programme (Figure 8). The role of the PI as a transducer to hypertrophic signals is fully documented[116,138]. There is evidence that Na^+-current, cAMP and the cytoskeleton may also play a role in signal transduction[113]. However, the precise molecular mechanism of proto-oncogene induction and fetal gene switches of the hypertrophy stimuli are far from clear.

Conclusions and future directions

Cardiac hypertrophy is an adaptive mechanism in response to disease states that produce increased work load. It involves an increase in myocardial cell size, proliferation of supportive tissues and other associated structural changes. Alterations in gene expression play an important role in this adaptive process, including alterations in contractile protein content and composition, the induction of a programme of embryonic gene expression such as ANF, and the expression of proto-oncogenes and other IEGs. The signalling mechanisms that activate and regulate these various alterations in cardiac gene expression during LVH are far from clear. Mechanical stretch directly induces gene expression in cardiomyocytes. Information about the genes that determine cardiac specificity during physiological development is still necessary to understand gene regulation during hypertrophy. Whereas in skeletal muscle both E-box dependent and E-box independent pathways exist, only E-box independent pathways have been found in cardiac muscle so far. Knowledge of cardiogenesis can be applied to target the expression of transgenes to specific cardiovascular compartments, and will provide a molecular framework to understand the development of cardiac malformations. The unraveling of the sequence of molecular events that initiate hypertrophic growth might provide the basis for the understanding of the development of decompensated heart failure. Identification of appropriate molecular markers will result in an important breakthrough in unfolding pathophysiology of LVH.

Although α-adrenergic stimulation is a potent stimulus for growth in neonatal ventricular cells, its role in hypertrophy in intact adult myocardium is not understood. The RAS appears to be an important contributing factor to the development of LVH. Our studies with ACE inhibitors, and others have shown a clear tendency in reversing the cardiac structural changes. Angiotensin-II has been suggested to work as an autocrine/paracrine factor regulating growth of heart and LVH by augmenting the cardiac gene expression. However, we still do not know whether it is the local or systemic A-II that is important in cardiac growth. Recently, we have shown that cardiac RAS plays a critical role in the pathogenesis of LVH. Nonetheless, A-II causes hypertrophy of cardiac myocytes and mitogenesis of nonmyocytes via AT_1 receptor stimulation. Elucidation of the mechanisms of A-II-induced cardiac growth and hypertrophy deserves further investigation because A-II is clearly emerging as one of the most critical mediators of cardiac hypertrophy *in vivo*. Future studies may permit us to design novel therapeutic strategies to heart failure.

Ecology of desert mammals

Ishwar Prakash

Desert Regional Station, Zoological Survey of India, 107 Kamla Nehru Nagar, Jodhpur 342 009, India

The Thar desert of western Rajasthan exhibits a rich mammalian diversity. In recent years, however, the number of large mammals, artiodactyles and carnivores, has drastically dwindled due to expansion of human population. They are being replaced by small mammals, shrews and rodents. The highly adapted *Gerbillus gleadowi* is a predominant species in the extreme desert largely dominated by sand dunes. The sandy plain in the central desert is the most species-rich habitat and is inhabited by 68 mammal species. Certain rodents like *Cremnomys cutchicus* and *Mus phillipsi* are found in the rocky habitats. The transformation of desert grasslands to irrigated agricultural fields is changing the biodiversity scenario in the desert. Consequently, typical desert-adapted, endemic mammals are vanishing and they are being replaced by mesic elements. Behavioural adaptation of mammals for survival in the inhospitable desert environment is discussed in this paper.

THE Indian Thar desert is located on the south-eastern fringes of the Great Palaearctic Desert, extending over two continents, from Sahara to Gobi desert. Sixty per cent of the Indian Thar is situated in western Rajasthan. The Archaean Aravalli range borders it in the east. The time and origin of the Thar desert still remains a disputed subject. On the basis of archaeological and historical evidences it was regarded to be of recent origin, xeric conditions having been established due to unlimited exploitation and destruction of vegetation[1,2]. However, recent geological[3], geomorphological[4] and palynological[5,6] studies point out that Thar is a very old desert and its aridity has been established over a long and continued period. The floristic and faunal evaluation of the desert biota confirms the latter view[7,8]. The arid region of western Rajasthan is not a vast stretch of sand dunes, but is interspersed with low hills and gravel plains. Human habitations are scattered all over since it is the most populated desert of the world, 78 humans per km^2. Consequently, the desert presents an interesting intermingling of habitats occupied by a species-rich mammalian fauna.

Mammalian abundance

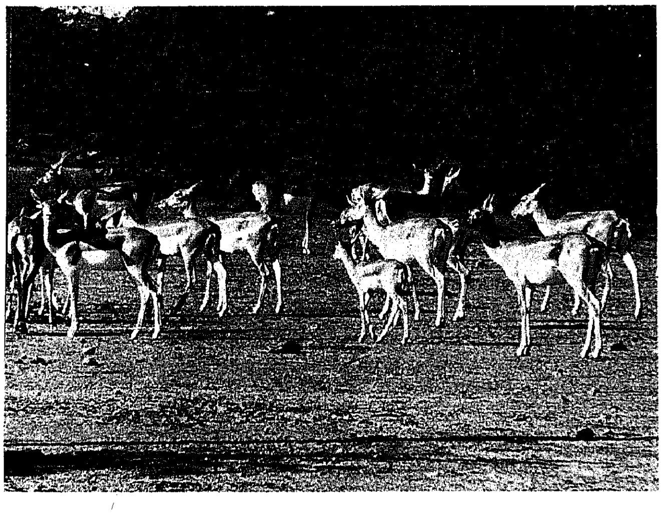
During the beginning of the present century, when human numbers were low, the desert region sustained a great preponderance of larger mammals. The now-extinct cheetah, *Acinonyx jubatus* was distributed throughout the desert and was commonly found around Jaipur[9]. Black buck, gazelle and wild boar have also been widely reported[10]. Herds of two hundred wild ass, *Equus hemionus khur* were reported from Bikaner and Jaisalmer[11]. The medium-sized mammals, the caracal, wolf, jackal, desert fox, desert cat, plentiful up to 1950, have almost vanished. This is mainly due to shrinkage of their native habitat, which is now being taken over by man for agriculture. The larger mammals are also being replaced by smaller mammals like insectivores and rodents. However, the blue bull, *Boselaphus tragocamelus* has benefited by the expansion of agriculture. This is because they are not killed on sentimental grounds. During the 1950s and the 1960s, the house shrew, *Suncus murinus* was collected only from residential premises and their vicinity. Later, during 1970–1971 trapping of small mammals was taken up throughout the desert of Rajasthan. It yielded a few shrews from crop fields, but our recent studies (1993–1994) revealed a high preponderance of this insectivore, especially in the crop fields[12]. The house shrew has apparently altered its ecological niche from houses to crop fields. Likewise, with the fast-changing landuse pattern, the density of several small mammals has enhanced like that of the bush rat, *Golunda ellioti* and the metad, *Millardia meltada*, which were seldom collected earlier. Moreover, a few species which did not occur in the desert have invaded it from Peninsular region, like the bandicoot, *Bandicota bengalensis* and the little mouse, *Mus terricolor*[13] which inhabit the irrigated crop fields. The mammalian scenario in the xeric environment is fast changing with man's intervention.

Habitat preference

The sand dune-dominated, tree-less, 100 mm rainfall region in the extreme western zone of Jaisalmer and Barmer districts is largely inhabited by the hairy-footed gerbil, *Gerbillus gleadowi*, which is endemic to the Thar desert. Its preponderance in the region is astonishing, about 40 gerbils/100 snap traps/24 h compared to 1–8 rodents per 100 traps per 24 h in other parts of the desert. The nocturnal species has been found to be one of the most adapted rodents as it is highly salt-tolerant and is more renal efficient than any other desert mammal[14].

Another finding we have made is that the porcupine occurs among tall sand dune systems of the extreme desert[15]. Elsewhere, *Hystrix indica* inhabits rocky habitat. Is this isolated population thriving in the deep desert, probably since times prior to deposition of sand and when it was a continuous stretch of hills? Similarly the relict Deccanean rock rat, *Cremnomys cutchicus*, occurring on every hill scattered throughout the Thar desert of Rajasthan, is at present the most abundant small mammal over the Aravalli range[12]. The central desert receiving average annual precipitation up to 400 mm is relatively a species-rich region because of diversity of habitats, the rocky outcrops, gravel plains, lakes, beds of ephemeral rivers and village complexes. In the rocky habitat, thickets of *Euphorbia caducifolia* provide shelter to the desert hare *Lepus nigricollis* and several species of mice. Crevices in the rocks are the special niche of the most abundant *Cremnomys cutchicus*. The larger caverns and caves are occupied by about 16 species of microchiropteran bats, only sometimes by rare species like wolf, jackal, hyaena and panther. Over the hillocks, which are protected from grazing livestock, porcupine is also found.

Village settlements occur in every habitat in western Rajasthan and they provide an important habitat for mammals. Whereas the magnificient black buck has almost vanished from the desert region, its free-living populations are still found around villages of Bishnoi people, who regard it sacred and protect it. Along with black bucks, the Indian gazelle, *Gazella bennetti* also congregates around Bishnoi habitations. The desert cat, *Felis silvestris* has so much intermingled with the domestic cats that it is difficult to find a pure-bred wild form. Old buildings, forts and deep wells are inhabited by microchiropteran bats. The two megachiroptera, the flying fox, *Pteropus giganteus* and the smaller frugivore *Cynopterus sphinx* are found over large trees in gardens. The striped squirrel, *Funambulus pennanti* is the most common mammal in the vicinity of human dwellings.

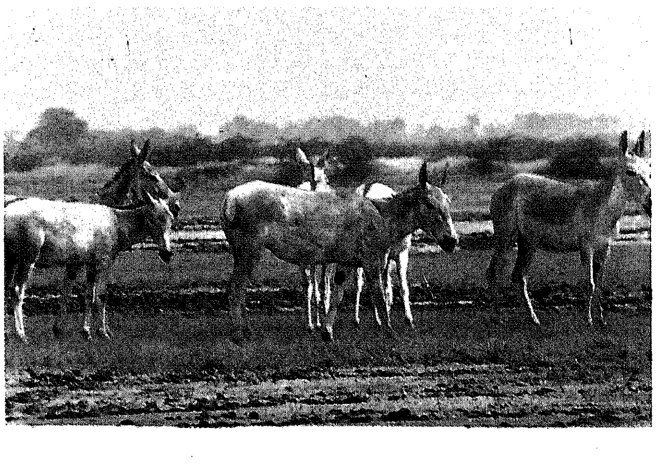


Early during the century the black bucks (*Antelope cervicapra*) were found in the desert region in groups of 5000 to 8000. At present, however, free-roaming antelopes are found only in the vicinity of Bishnoi village complex. This community of desert dwellers protects wildlife and trees on religious grounds. It is an unique example of human–animal relationship. (Photo: B. S. Lamba).

The northern desert, Sri Ganganagar and Hanumangarh districts have been transformed from open desert grasslands to irrigated cropping with the advent of Gang Canal during the 1930s. At present the Himalayan water is flowing into the desert up to Jaisalmer through the Indira Gandhi Canal. Extensive agriculture has already come up very close to Bikaner. In this irrigated region the moisture regime pattern in the sand has been totally altered, it is moist all the year round. Consequently, the vegetation type has changed and typical deserticolous animals are being replaced by mesic forms. The gazelles have migrated to dry zone and they are being replaced by the blue bull. The highly-adapted desert rodents (*Gerbillus*, *Meriones*) have been replaced by mesic *Bandicota*, *Mus* and *Millardia* (Table 1). The latter species are serious pest of standing crops and very dangerous from the epidemiological point of view as they are very susceptible to the plague bacillus. Moreover, the desert is losing its endemic xeric fauna, which is not found anywhere else in India, due to altering landuse pattern.

Desert adaptations

The desert animals and plants are confronted with thermal extremes, paucity of drinking water and food, and scanty shelter. The desert mammals have evolved a series of adaptive strategies for their survival in the inhospitable desert environment. About 80% mammals inhabiting the arid zone are nocturnal, and by restricting their activities to cooler nights, they avoid the heat of the day. Moreover, when the air temperature falls below −5°C, most of

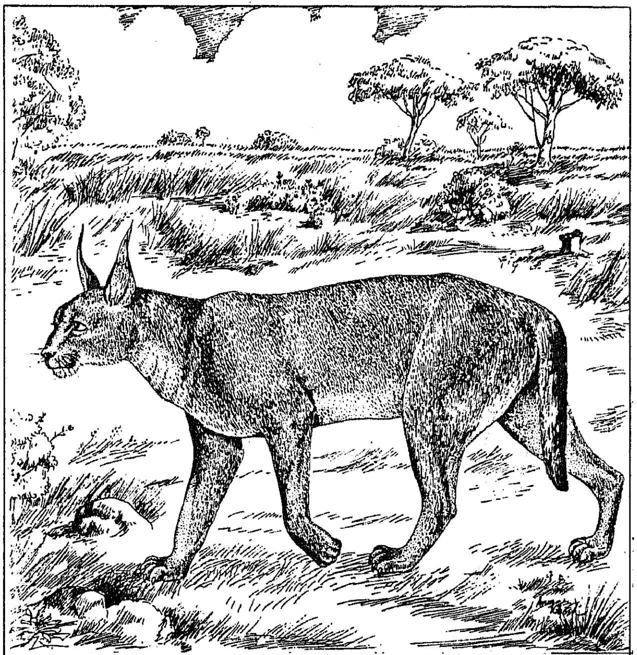


Herds of wild ass occurred in Bikaner and Jaisalmer before the turn of the last century. At present, *Equus hemionus* is restricted in the Little Rann of Cutch. (Photo: S. P. Sanyal).

them cease their activities and enter their hideouts. It has been observed that during summer, the Indian gerbil, *Tatera indica* ventures out of its burrow at about 17.30 h and the peak in its activity is reached at 23.00–24.00 h and terminates early in the morning. However, during the winter season when the nights are very cool, the peak activity is advanced, soon after dusk, at about 19.00 h and ceases by 24.00 h. By restricting its outside-burrow activity, it avoids exposure to the mid-night extreme cold. Likewise, the diurnal desert gerbil, *Meriones hurrianae* also shifts its diel activity into Bimodal pattern during summer months: during mornings and evenings. However, in winter it forages all through the day. Desert mammals shift their diel activity to comfortable periods to avoid the extremes of temperature.

Table 1. Succession of species replacement in the desert region under Indira Gandhi Canal Command

Period	Mammals (arranged in the order of abundance)
Prior to incoming or irrigation	*Gazella, Gerbillus, Meriones, Tatera*
25 years after incoming of irrigation	*Gazella, Tatera, Millardia, Meriones*
65 years after	*Boselaphus, Millardia, Tatera, Mus, Bandicota*



The caracal (*Felis caracal*). Locally known as *Siyagosh*, the caracal was a rare animal even at the turn of the last century. Distributed in deserts of Iran, Arabia, Pakistan and the Thar desert, at present, it is considered as a threatened species. Caracal is stout mammal with long limbs, larger than a cat, long ears with a tuft of black hair on the tip. Inhabits open grasslands and feeds on birds and small mammals. It has been reported to spring upon low flying birds up to about two metres. It is so powerful that it can chase and kill a gazelle. People used to tame and train it to catch peafowls, cranes, hares and other medium-sized mammals. The caracal is extremely agile and swift. When let loose amongst pigeons feeding on the ground, the caracal strikes down 10–12 birds before they can escape by flight. Alas! this magnificient animal is on the verge of extinction in the Indian Thar desert [Diagram: Arun Ghosh].

The smaller mammals (56%) have adapted to live a fossorial life; insectivores (4 species), medium-sized carnivores (13), pholidote (1) and rodents (17). The temperature inside the burrows does not fluctuate as much as the air temperature does during the day (Figure 1). When the desert gerbil, *Meriones hurrianae* develops hyperthermia due to continuous exposure to sun, it intermittently visits the cooler environments of the burrow and unloads the excessive heat. This may be the reason that diurnal rodents excavate extensive, multi-tier burrows as compared to the nocturnal ones. All the mirochiropteran bats (25% of mammal species) inhabit cooler environments of caves, tunnels, and ruins of buildings.

Almost all the mammals are very versatile as far as their food habits are concerned. It is not surprising to find that 90% of the stomach contents of the insectivorous *Suncus murinus*, examined all through the year, constituted leaves of an inedible shrub, *Mimosa hamata*. Likewise, stomach contents of carnivorous desert fox, desert cat and jackal were found full of fruits of cucurbits

and berries of *Ziziphus nummularia*. The seedivorous-desert rodents switch over to insects during the summer months when vegetation is without any water content. Insect bodies contain about 80% water. The shift to insect food during summer also helps them in osmoregulation. The gerbils show spectacular fluctuations in feeding on various plant parts over the year depending on their availability in the desert ecosystem. Our study[16] revealed that during winter, when the seeds are available after flowering season, the gerbils feed on maximum quantity of seeds, 60% of the total. During monsoon, when green food is available, blades of grasses and leaves of herbs are consumed (30–40%). But during summer, they totally depend on stem, rhizomes of sedges and grasses; and insects. Moreover, during summer when food is scarce, the merion gerbils have been observed to scent-mark dry clumps of grasses, probably to indicate their territoriality over it to other conspecifics. Omnivory is one of the major strategies for survival in the desert.

Most mammal species coincide their maximum breeding time to monsoon months because of the prevalence of conducive environmental condition and availability of green food. Our field data has clearly shown that the survival rate of the young born during the latter half of the year is significantly ($P < 0.01$) superior to those born during the first six months of the year. Moreover, among the mammals which litter all the year like the desert hare, *Lepus nigricollis dayanus* (Table 2), the largest litters are born during July to October, the rainy months.

Zoogeography

A detailed analysis of mammalian distribution in African and Asian deserts has revealed that some genera like *Meriones* and *Gazella* are spread from Sahara to Gobi desert and find their south-eastern limit in the Thar desert. A few species are Turano-Tharian and about 50% species exhibit oriental affinities (Table 3). Three mammalian species and 20 subspecies are Tharian in origin.

Desert climate and its dynamics

D. R. Sikka

40 Mausam Vihar, Delhi 110 051, India

Basic characteristics of desert climate are discussed in relation to aridity indices based on water balance and energy balance consideration. The dynamical aspects of the underlying causes in terms of tropical Hadley cell, orographically forced subsidence and large scale ocean–atmosphere interactions are elaborated. Climatological aspects of the Thar desert (Rajasthan) in India and a review of the present and past climates of the region are presented. Interannual fluctuations of arid conditions are discussed in terms of several parameters. Local and regional dynamical aspects of the desert climate as revealed by recent field experiments are discussed. Anthropogenic causes of desertification are discussed in terms of the biogeophysical feedback processes such as albedo, soil moisture and roughness length. Recent work of several workers, employing general circulation modelling experiments to study the sensitivity of land surface processes to desert climate are briefly reviewed.

DESERTS or arid zones are one of the important components of the Earth's environment. They are fragile ecosystem where vegetation is absent or scarce as moisture is insufficient to support it. They are progeny of global climate system under the influence of large scale land–ocean–atmosphere–cryosphere interactions.

Two systems of climatic classification are usually followed after Koppen and Thornthwaite. In the Koppen's[1] system desert or arid climate is characterized by regions where mean annual precipitation is low (< 250 mm) and surface air temperature is high. The Thornthwaite's[2] system is based on water balance or hydrological approach and compares the mean annual rainfall against mean annual potential evapotranspiration (PET). Deserts (arid and semi-arid regions) occupy nearly 30% of the land area of the Earth and nearly one sixth of world's human population live in these environments. Obviously extensive scientific work on various aspects of the desert environment has been done. Our objective is to consolidate briefly information on desert climate, mostly restricted to near-surface climate.

The following indices are usually used to define aridity or moisture availability:

$$\text{Thornthwaite's Index } I = \frac{\text{Mean annual precipitation } (R)}{\text{Mean annual potential evapotranspiration}}.$$

Different classes of arid zones are described as – (i) Hyperarid: $I < 0.05$ (almost absence of vegetation); (ii) Arid: $0.05 > I < 0.20$ (dry zone where perennial agriculture is not possible); (iii) Semi-arid: $0.20 < I < 0.50$ (shrub lands where rainfed agriculture is practiced).

Moisture index (I_m) is usually defined as:

$$I_m = \frac{100\,S - 60\,d}{\text{PET}},$$

where S is water surplus and d is water deficiency. A region is considered having desert climate if I_m is below – 60 and this limit on I_m generally agrees with Koppen's classification BW for the deserts.

An entirely different method of quantification of aridity is after Budyko[3] and follows the energy balance approach in which net radiation (Q^*) received at the surface of the earth on annual basis is compared against the mean annual precipitation (R). (Q^*) is given by the well-known energy balance equation

$$Q^* = (Q + q)(1 - x) - (\text{LWu} - \text{LWd}) = H + LE + G,$$

in which Q and q are the direct and diffuse solar radiation received at earths surface, x is the albedo of the surface, LWu and LWd are the upward and downward long wave emissions by the earth–atmosphere system respectively. The net radiation is used in three major ways, viz. (i) in transporting sensible heat (H) upward by turbulent eddies, (ii) in removing water/moisture from surface by evaporation and transpiration (LE) and, (iii) in conducting heat into the soil (G). The small portion of energy used in photosynthesis is neglected for the energy balance purpose. Lettau[4] defines a dryness ratio by comparing Q against heat required to evaporate rainwater

$$\text{Dryness ratio} = \frac{Q^*}{LR},$$

where L is latent heat of vaporization.

For hyperarid regions dryness ratio is > 10, for arid regions it is 7 to 10 and for semi-arid regions it is 2 to 6.

Global distribution and mechanisms of deserts

In Koppen's classification the desert climate is designated as BW and these regions are surrounded by the climate type BS. The marine deserts, where rainfall is also scanty, are designated as BM. The world's major deserts in different continents are: (i) Sahara, Saudi Arabia, East Africa, Namib, Kalahari in African continent, (ii) the Thar, Taklamakan and Gobi in the Asian continent, (iii) the Great Sandy and Simpson deserts in Australia, (iv) Mojavet, Sonaran and Chiliuahan in North America, and (v) Peruvian, Atacama, Patagontan in South America. Oceanic deserts exist in the equational central and eastern Pacific where the SST is < 26°C and under the sub-tropical high pressure belts in north and south Atlantic and Pacific Oceans, in the South Indian Ocean and over Western and Central Arabian Sea. Coastal marine deserts exist off the major ocean upwelling regions or where cold ocean current prevail. Any geographical atlas depicts the distribution of major deserts over land. From this distribution it becomes apparent that most of the deserts over the Earth are located within the descending limb of the direct Hadley circulation whose ascending limb on annual average basis lies in the near equational region. The ascending and descending limbs shift poleward (equatorward) during summer (winter). Thus in the sub-tropical belts some rains occur in the desert regions during summer due to moisture incursion with the poleward excursion of the Intertropical Convergence Zone (ITCZ) or Monsoon Trough. A few rain spells may also occur in winter under the equatorward extension of baroclinic disturbances. The subsidence motion under the sub-tropical high pressure belts does not favour convective motion or cloud formation. The sub-tropical deserts are further desiccated if a region lies under the influence of cold currents or off oceanic upwelling regions such as the Namib desert in South Africa, the Atacama and Peruvian deserts in South America and the East African desert of Somalia. The inner continental deserts within or close to the sub-tropical belts are also sustained by the downward motion on the leeward side of major mountain barriers such as the Taklamakan desert in Asia and Patagontan desert in South America. The aridity of the Interior Karnataka, parts of Maharashtra and Andhra Pradesh States of India is also ascribed to the rain shadow effect of the Western Ghats.

Characteristics of desert climate

Low rainfall and high temperature are the most conspicuous characteristics of desert climate. The mean annual aridity indices are different for different land deserts of the world and the aridity is highest for the core Saharan and Peruvian deserts, followed by the Saudi Arabian, East African and Gobi, Australian and South African deserts. It is low for India's Thar desert and the North American deserts of California and Mexico. It is observed (Berkofsky[5]) that there are regions in the Saharan, the Australian and the Namibian deserts where the annual rainfall is almost negligible < 50 mm. Compared to that most of the Thar desert in India receives considerable rainfall (100–300 mm).

Present and past climates of Thar desert of India

The Thar desert of Sind Province of Pakistan and Western Rajasthan region of India is a meteorologically homogeneous region where physiographic and anthropogenic conditions are somewhat comparable to the contiguous Saharan region to its West. The Aravallis range in Rajasthan defines the eastern limit of the Thar. Most spectacular amongst the land forms in West Rajasthan are the sand dunes which contribute about 40% of area of the region. The dunes are not contiguous and dune-free corridors exist. Some of the dunes are stabilized whereas others are less stable and wind erosion is a common feature from dunes to dune-free areas. The Thar region is under the influence of the Indian South-west monsoon (or summer monsoon) during July and August and occasionally rain-producing weather disturbances like 'depressions' and 'lows' penetrate up to parts of Rajasthan triggering rain events in the Thar. The precious rain events in Thar desert support a large population with above average growth rate than the average growth rate of India.

Climatology over the Western Rajasthan

The climate of the Western Rajasthan is controlled during the summer monsoon (June–September) by the seasonal heat low over Sind–Western Rajasthan region and during winter (December–March) by the Siberian anticyclone at the surface level. Thus the wind flow near the surface is from South West/West during the summer monsoon and from a general NW direction during the winter. At the upper tropospheric level wind flows from the east during the summer monsoon and from the west in the winter season. In the transition months of October and November in autumn, the pressure gradient is very slack. In the spring/early summer during April and May intense heating during the day, coupled with existence of pressure gradient in the formative stage of the summer time heat low, supports strong dust-raising winds. The almost clear weather pattern during late January to June is interrupted by the passage of a western disturbance which occasionally affects the weather of Western Rajasthan such that a few mild rain events occur during January–March and dust storms from April to June.

Rainfall

The main rainy season is during July and August when almost 80% of the annual rain occurs. Figure 1 shows the annual distribution of rains for West Rajasthan along with the coefficient of variation. The monsoon seasonal rainfall follows the annual rainfall and decreases from about 500 mm over East Rajasthan to about 100 mm over extreme western portion of West Rajasthan. The rainy days also decrease from East to West Rajasthan. The coefficient of variation is also higher over West Rajasthan. The rainfall is mostly convective in nature such that an intense weather system even in one day produces 50% or higher of the annual rainfall in one day. The highest one-day rainstorm of Rajasthan has occurred over Banswara in East Rajasthan (559 mm). Figure 2 shows the one-day probable mean precipitation (PMP) for Rajasthan. Dhar *et al.*[6] have studied the depth–area–duration of some of the severe most rainstorms that have occurred over Rajasthan for 1- to 5-day and have reported that for 100 km^2 area the 1-day rain depth has been approached in the rainstorm on 19 July 1981. The same rainstorm produced a rainfall of 265 mm at a station in Nagaur district in West Rajasthan. The mean annual rainfall of West/East Rajasthan is given in Table 1.

Length of the monsoon rainy season

The monsoon rains begin in West Rajasthan by 10–15 July and end by 7 September. In the mean, the season lasts for about 50–60 days. Inter-annual variations in the duration of the season are marked due to early arrival and late cessation of the rains and in extreme cases the season can last between 40 and 70 days. This large fluctuation has marked effect on the quantum of rainfall in this desert.

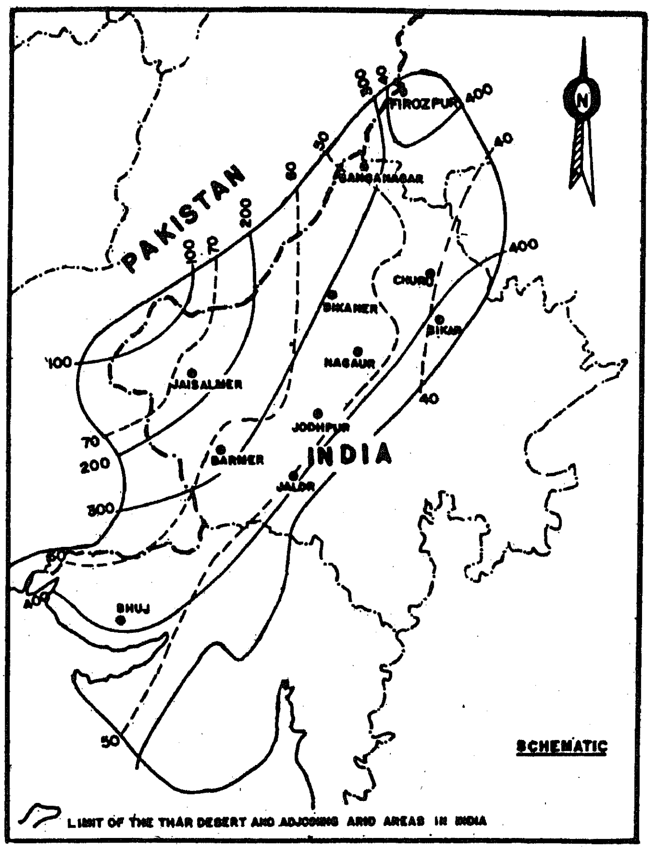

Figure 1. Mean annual rainfall (in mm, full lines) and its coefficient of variation (in %, dotted line) over West Rajasthan.

Fluctuation in aridity index

Nityanand Singh *et al.*[7] have examined the year-to-year fluctuations of the area under less than 560 mm of annual rains, which they call as arid area, over India, North India and Peninsular India. For North India (north of 20°N), the arid area, as defined above, covers 43×10^4 km^2 with a standard deviation of about 14.8×10^4 km^2 (coefficient of variation, 34.3%). This area shows expansion and contraction on inter-annual basis (Figure 3) and in an extremely dry year like 1918 or 1987 major part of north India experienced arid conditions whereas the area contracted to cover only parts of West Rajasthan in extremely good monsoon year like 1917 or 1961. In recent years there is a declining tendency in the arid area with a westward shift in heavy rainfall events. Figure 4 after the work of Ramakrishna[8], shows that Thornthwaite's mean moisture index line of – 80% has shown east-west fluctuations around its long term normal position – the protrusion to west being somewhat large in the decade of 1971–80 (wet decade). This and the rainfall analysis of Rajasthan suggest that in recent decades the Thar desert appears to have shrunk instead of expanding to the east. Mean annual aridity index calculated by Parthasarathy and Rakhecha[10] is given in Table 2 along with annual rainfall and annual maximum and minimum temperatures.

Droughts in Rajasthan

Table 3 shows the individual drought years (annual rainfall departure from long term normal < 25%) over the meteorological sub-divisions of West and East Rajasthan as well as the drought years which are common to both the sub-divisions.

It is clear from Table 3 that West Rajasthan is more prone to drought and several of the drought years are not common between the two sub-divisions even though they are contiguous zones. Besides, the common drought years are mostly those in which the country as a whole had suffered from bad monsoon (rainfall < one standard deviation for the country as a whole). These drought years are those in which India is affected by the adverse effects of planetary scale ocean–atmosphere coupled system ENSO phenomena. Sikka[11] was among the first to suggest ENSO–monsoon relationship and since then many researchers have further investigated this relationship. Rakhecha[12] has listed the years of excess rainfall (> 50% normal) and deficit rainfall (< 50% normal) years for the period 1871–1990.

Stability and moisture content

The Thar desert of India witnesses extreme surface air temperature during the year. The maximum temperature in May–June touches 50°C and the minimum temperature in January–February reaches $-3°C$ or even less in extreme cold wave conditions. The lowest temperature recorded at Jaisalmer is $-5.9°C$ with the mean monthly extreme lowest temperature of $-2°C$ in January. Whereas the diurnal temperature range in summer and winter is normally about 20°C, it reaches 25°C under extreme conditions.

The soil temperature at surface in summer is even 10°C warmer than the maximum surface air temperature near noon and it is about 3°C colder than the minimum air temperature in winter. This indicates that super adiabatic lapse rate (highly unstable lapse rate) prevails during the day time in summer and a strong inversion (highly stable lapse rate) exists in winter near the surface from dusk to early morning. Ramakrishna *et al.*[13] conducted a special experiment from May 1987 to April 1988 at stable and unstable sand dunes in the area to measure soil temperature and surface air temperature. The data showed that the maximum soil temperature of 55°C or more was recorded in May 1987 on all faces and again temperature even over 60°C, were recorded in September 1987. During November there was a considerable fall in the maximum temperature for the soil and air. Thus, maximum difference in soil to surface air maximum temperature recorded during the experiment reached a value of 21.2°C at the crest during June 1987, showing high super adiabatic lapse rate over the dune surface during day time. Minimum soil temperature during early morning was highest in May 1987 (about 28°C) and it showed considerable fall in November 1987. The minimum air temperature was higher than the minimum soil temperature, indicating inversion lapse rate (stable) from the soil to the surface air layer during night/early morning. The lapse rate above the surface layer is nearly adiabatic up to about 600 hPa in May and June during day hours under the influence of intense solar heating coupled with thermal and mechanical turbulence. During the monsoon months of July–August the lapse rate is mostly between dry-adiabatic and moist adiabatic, favouring conditional instability, which promotes moist convection under favourable conditions. Rajkumar *et al.*[14] while analysing MONTBLEX data at Jodhpur have found that even during the monsoon season, when the ground is wet and the sky is cloudy, the lapse rate in the lowest part of the atmosphere in the PBL is mostly stable during day and night hours. Usually most of the moisture resides in the mixed layer or planetary boundary layer during the monsoon period and it decreases sharply above the low level inversion layer which acts as a lid for the moist processes and suppression of convective clouds. During winter the lapse rate in the lower troposphere is statistically stable under normal conditions except during rain episodes under the influence of western disturbances.

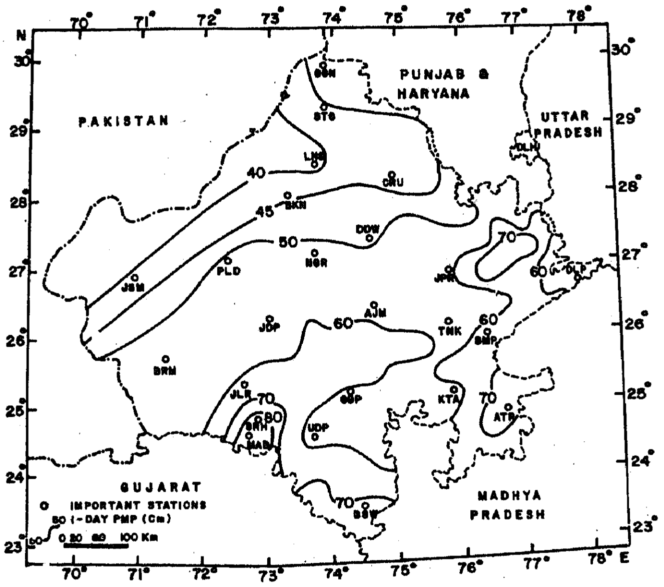

Figure 2. One day probable maximum precipitation over Rajasthan (after Rakhecha[12]).

Solar radiation and sunshine

Thar desert region receives intense solar heating during April to June and again in September and October. The

Table 1. Mean annual and monsoon season rainfall statistics for Rajasthan

Region	Annual rainfall (mm)	C.V. (%)	Monsoon season rainfall in mm (% of annual in parenthesis)	No. of rainy days
West Rajasthan	309	40	275 (88)	17
East Rajasthan	679	26	623 (92)	34
Rajasthan as a whole	468	31	425 (91)	29

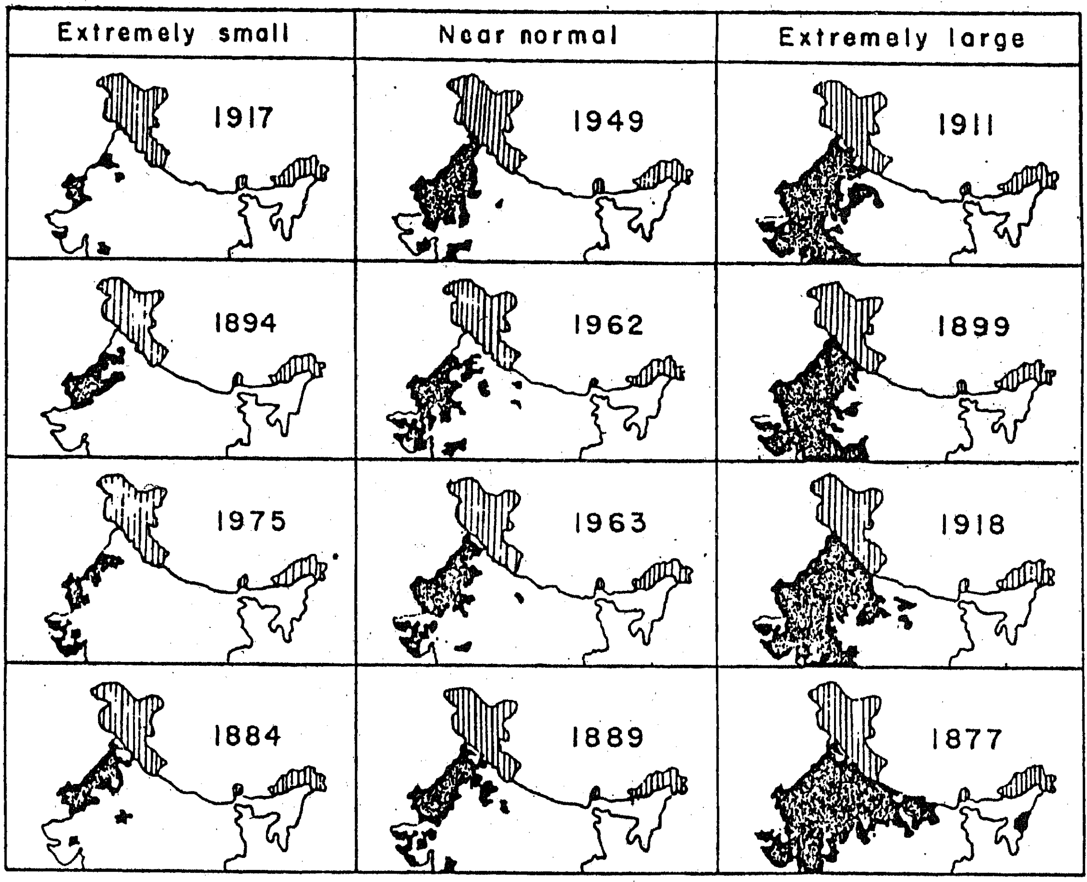

Figure 3. Fluctuations in arid area of North India in some typical years (after Nityanand Singh *et al.*[7]).

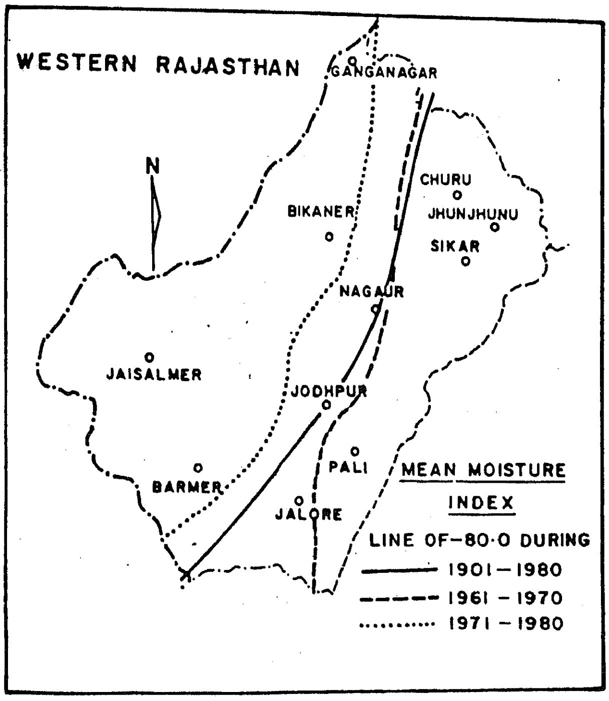

Figure 4. Shifts in the mean moisture index line of – 80.0 over western Rajasthan (after Ramakrishna[8]).

maximum global radiation (direct and diffuse sky) per day is 700–800 cal/cm^2 per day in May and minimum of 400 cal/cm^2 in January with annual average of 560 cal/cm^2 per day. Under overcast sky conditions on a particular day the solar radiation is reduced to 190 cal/cm^2 per day. Solar radiation decreases in July and August and a secondary maximum occurs in October. Dust and clouds are major factors in attenuation of solar radiation. Maximum hours of bright sunshine, reaching 10 h per day occur in May and October[15,16]. According to their estimates[15,16] global radiation of 60 cal/cm^2/h is available for 4 to 5 h per day (1100 to 1600 h), indicating high potential for solar energy in the Thar desert. Desikan *et al.*[17] showed that there is a decreasing trend in solar radiation from 1965 to 1985 over Jodhpur, perhaps due to higher dust load.

Surface winds

Generally the winds near the surface have westerly component during major part of the year. They are stronger over the West Rajasthan than over the East Rajasthan. Surface winds reach a value of 25–30 km/h over West Rajasthan during May–June. Such strong

Table 2. Mean annual aridity index rainfall maximum and minimum temperatures for some stations in West Rajasthan

(30 years)	(23 years)	(18 years)

winds raise tremendous dust from the loose sandy soil of the region and the dust is transported eastward over neighbouring states of India.

Dust layer and dust storms

A dust layer from ground up to 8–9 km height is built up gradually from March to June which affects the horizontal and vertical visibility. Dust depletes solar radiation by 30%. During intense episode of dust-raising winds or following the dust storm day the sun is obscured from view even during the mid-day. The dust (sand) raising capacity of the surface air is proportional to the cube of the wind speed and hence the capacity of the winds to raise sand from the desert increases sharply after a wind speed of 10 km/h. The average soil loss in the Thar desert varies between 30 and 60 kg/m^2 per day during April to June[18].

Dust storms also occur more frequently in West Rajasthan than over the East Rajasthan during April to July, the frequency, however, being highest over Ganganagar (17 days), followed by Bikaner (15 days), Jodhpur (6 days) and Jaisalmer (2–3 days). Dust storms are often accompanied by thunderstorms (dry and wet). The annual number of thunderstorm days is about 10 over West Rajasthan and increases to about 40 over East Rajasthan. Singh *et al.*[19] have studied the hygro-thermal regime during a duststorm period in May 1990 under the MONTBLEX Programme.

Parameters of the hydrologic cycle

The annual PET over West Rajasthan varies from 2000 to 2500 mm and reaches a maximum of over 3000 mm in May–June. PET for monsoon months is about 600–800 mm. As the annual and monsoon seasonal rainfall figures are below the PET, moisture deficit exists over West Rajasthan throughout the year under normal conditions. However for the East Rajasthan moisture surplus does occur during July and August, particularly in years of excess rainfall. Since water at the surface is available only during rain spells in monsoon season and in winter, the evapotranspiration is high only during periods of rain spells. Soon thereafter the water gets evaporated due to high winds and high temperature. In the long dry period, the evapotranspiration is low as the vegetation closes its stomata to restrict transpiration in order to survive itself against moisture stress. Thus the average annual evapotranspiration over the Indian part of the Thar desert is about 400 mm. Since the soil in the desert is sandy, most of the rainfall percolates below the soil and is stored as soil moisture and very little is left for runoff. Even the run off percolates below the soil and the streams dry off down the course rather fast. Studies on soil moisture by Abichandani *et al.*[20] and Gupta[21] show that soil reaches field capacity in intense convective episodes and is charged with water up to even 100 cm depth. While natural hardy vegetation near the surface soil dries up in the dry season, deeper parts of its roots are sustained by moisture supply from the deep soil and with the first rains of the monsoon the desert springs up into life. Ramakrishna *et al.*[22] have discussed in detail about the annual moisture regime variability and its impact on agriculture in Rajasthan desert.

Climatic fluctuations over Rajasthan during instrumental period

Several workers have examined the question of climatic fluctuations over Rajasthan since the first major drought occurred in 1951 after India's independence[23–30]. All the studies suggest that there has been no major shift in the rainfall or temperature climate of Rajasthan. Pant and Hingane[29] showed that there is very little trend in Rajasthan rainfall over the last 100 years. However a small positive trend exists over East Rajasthan and neighbouring region of West Madhya Pradesh, Haryana and Punjab for the monsoon season rainfall and annual rainfall. Based on their analysis Pant and Hingane have rejected the results of Winstanley[31], suggesting that the rainfall of NW India was declining due to the equatorward shift of polar circulation and consequent equatorward shift of the ITCZ. They also conclude that a gradual decreasing trend in mean annual temperature of NW India is observed. The increasing rainfall and decreasing temperature trends are consistent and are attributed cautiously by the authors, to a progressive increase in the irrigated area. Ramakrishna and Rao[32] have also shown trend toward more rainfall, lower temperature and lower incidence of dust-storms in the command area of Indira Gandhi Canal.

Climate change scenario for Rajasthan due to anthropogenic activity

There is considerable worldwide concern about the possibility of climate change in desert regions due to global warming under the increasing greenhouse effect being caused by anthropogenic activity. Several numerical experiments have been performed world-wide for climate change under double CO_2 scenario using equilibrium climate change and employing stand alone atmospheric GCMs and coupled ocean–atmosphere GCMs. Rajasthan is too small a region to be effectively studied through the results of numerical modelling experiments. The result of the experiments could be valid with some certainty for the global climate system and considerable uncertainty exists when they are applied to regions/subregions. Since Rajasthan rainfall is mostly determined by the south-west monsoon of India, any change in its intensity under the double CO_2 conditions would impinge upon Rajasthan rainfall and water resources. Sikka and Pant[33] showed that for the stand-alone GCMs the monsoon rainfall of northern India may increase by 5–10% and the surface temperature may increase by 1–2°C. However, in the latest results of Lal *et al.*[34] using a coupled atmosphere–ocean model and incorporating sulphate aerosol due to projected enhancement of industrialization, the rainfall showed decrease by about 5% and the temperature also showed decrease by about 1°C. In any case these scenarios are only suggestive and the magnitude of projected change is rather quite small, much smaller in comparison to the interannual or interdecadal variability of the meteorological parameters witnessed in the instrumental period. Thus there is hardly any cause for concern with regard to climate change due to greenhouse global warming over India or over Rajasthan desert. The real problem in desert climate is the inter-annual variability. Most of India is situated in the deep moist tropics, with major ascent centred over the warm north Bay of Bengal waters and adjoining monsoon convective regions over the Eastern Gangetic plain in the west and moist Bangladesh, SE Asia and South China in the East. So long as this moist convective regime is maintained by natural atmospheric dynamics, it would suppress advancement of the arid conditions of Western Rajasthan farther eastward into the Gangetic plain.

Appraisal of palaeoclimate of the Thar desert

The Thar desert region, like many other deserts has witnessed climate changes due to natural causes. Thus, it is expected that in the historical and pre-historical pasts, monsoon fluctuations due to natural causes such as change in earth–sun geometry and glacial–inter-glacial episodes lasting for hundreds of years would have affected the climate of the Thar desert. Besides tectonic disturbances in the Aravallis would have affected the courses of river systems such as the Chambal–Yamuna river system and the legendary Saraswati and Drishdawati rivers which once flowed through the desert. Many attempts have been made to reconstruct the palaeoclimate of the Thar desert by employing a variety of multidisciplinary approaches such as physiography[35], pollen data from the desert salt lakes[36], thermoluminescence chronology of fossil sand dunes[37,38], archaeological records and history of past civilizations which flourished in the Ganga–Yamuna–Indus–Saraswati river beds[39], glacial and inter-glacial chronology[40–44] and geomorphologic studies[45–49]. Pant and Maliekal[50] have given good surveys of the past climate changes from last glacial to the quaternary phase of the global climate. According to these studies the past climate history of Rajasthan can be grouped into the following phases:

Phase I (20000–10000 years BP, last-glacial). This was the period of ice age conditions with cold temperature and extreme aridity in Rajasthan. Several numerical experiments, using atmospheric general circulation models support this inference as the monsoon with ice age boundary condition is simulated to be very weak in the models with its northward limit restricted to about 15°N only.

Phase II (10000 to 5000 years BP). Increase in vegetation and lake water levels suggestive of a continued moist period in Thar desert. Lake pollen and other data support this inference. Onset of deglaciation weakened sand mobilization in the period.

Phase III (5000 to 3000 years BP). This is the most moist period with frequent floods. The rainfall is estimated to be between twice and thrice of the present. This period is, therefore, called as the climate optimum of the region with warm, humid and equable climate when great civilization of Mohanjo Daro and Harappa flourished at its peak and its decay set in toward the end of the phase – possibly by large fluctuations in the monsoon due to climate change from wet to the dry phase.

Phase IV (3000 BP to 18th century AD). This was the warm and dry period when the aridity had established once again and has continued almost unabated to the present with minor interdecadal and centennial scales of climate fluctuations in which somewhat wetter or drier regimes followed each other. This is supported by historical/archaeological evidence of rise and fall of post-Harappan cultures in the region like the painted grey ware (2800–2400 years BP) and the Rang Mahal culture (100 BC to 100 AD). The period between 600 AD and 1000 AD is inferred to be wetter and the period between 1400 and 1700 AD somewhat drier (Little Ice Age).

The interface between phase III and phase IV coincided with tectonic activity in the Aravallis region which brought changes in the courses of rivers Saraswati, Drishdawati, Sutlej, Ghaghar and Chambal. The drying out of the river bed of Saraswati and its feeding channels occurred and the glory of Saraswati was lost by the time of *Mahabharata*, i.e. 1500 BC or so[51]. Sand mobilization during this period correlates well with evidence about the desiccation of lakes[52]. Bryson and Baerries[53] suggest possibility of climate modification by human activity in the region during setting up of the natural dry phase which according to them would have led to more dust load and consequently aridity followed.

Local and regional dynamic studies on desert climate

Structure of summer-time heat low

In the recent years several special field experiments have been undertaken internationally and nationally in several countries to understand the dynamical structure of the atmosphere over desert regions. In India, the IITM Pune and the Gujarat Agricultural University, Anand are currently engaged with a land surface process experiment (LANDSPEX) over Gujarat region which is supported by the DST. Earlier in 1990, IITM carried out MONTBLEX[54] and a special observation on boundary layer processes was studied at Jodhpur. An elaborate experiment was carried out in the Arabian desert during the summer MONEX-1979 Programme[55]. The following results have emerged about the local/regional dynamics of the Thar/Arabian desert as a result of the above experiments and field studies carried out by the CAZARI scientists.

(i) Summer-time 'desert heat low' is a shallow cyclone at the surface which is replaced by a warm anticyclone above 1–2 km height.

(ii) Surface air temperature during most of the summer is 45–50°C and the surface soil temperature is higher by 10–15°C. Diurnal variation of air temperature is 20°C and surface soil temperature is 25 to 30°C. The soil cools rather rapidly with the onset of autumn and the winter minimum temperature reaches below the freezing point. Soil and air temperatures rise rapidly with sun rise and near-maximum temperature is reached by 1100 h and stays so for about 6 h in summer. By early night a surface inversion is set up even in summer.

(iii) The planetary boundary layer (PBL) is unique in summer (April to June) and is highly unstable for dry convection as super adiabatic lapse rate prevails. The thermal and wind-induced mechanical turbulence lasts for about 10–15 h during the day. The convective layer is up to 500 hPa (mixed layer height) in depth and the eddy transport of sensible heat is high from warm ground surface upward into the unstable PBL. This vertical advection of heat in the lower troposphere is about 3°C/day. During monsoon period (July and August) the PBL has sufficient moisture to realize conditional instability under favourable synoptic conditions.

(iv) The summer monsoon thermal 'low' undergoes quasi-periodic intra-seasonal oscillations on 5–7 and 10–15 day scales. These oscillations occur due to cooling above the mixed layer from an imbalance between the sensible heat flux divergence and the ground radiative heating. The dust load is mostly confined between the surface and mixed layer, which cuts off part of the solar radiation reaching the ground, leading to some decrease of temperature near the ground as well as reduction in vertical advection of sensible heat into the PBL. The heat law, thus, decreases in intensity (decay phase) and the mixed layer is somewhat stabilized reaching neutral phase from the convective phase.

(v) The dust layer plays a crucial role by absorbing incoming solar radiation and also by restricting outgoing thermal emission in the IR. Thus there is net radiative heating of 2–4°C/day in the troposphere above 700 hPa and net cooling of 6–8°C in the lower troposphere. This results in net cooling of the atmospheric column by 1–2°C at the top of the atmosphere. Radiation budget studies with *in-situ* and satellite-based observations confirm net tropospheric cooling on local and regional scales. As such, in order to sustain the desert heat low, it is necessary that energy is transported toward the desert by the large scale monsoon vertical circulation. This is accomplished by the moist ascent taking place over the convective regime centred over North Bay of Bengal and dry descent in the peripheral desert heat lows over the Thar and the Arabian deserts.

(vi) A two-cell structure in horizontal divergence prevails during the day in the troposphere in the heat low region with shallow convergence (at best up to 850 hPa) and divergence aloft up to mid-troposphere, topped by weak convergence in the upper troposphere. Maximum downward motion exists near the top of the mixed layer. During night time downward motion exists right up to the surface as the low level convergence is considerably reduced or even replaced by divergence.

(vii) Drag coefficient in the desert region[56] is 3 to 4 times higher than for the oceanic areas.

Bhide *et al.*[57] showed that at 500 hPa, heat sources and moisture sinks propagate westward on 10–15 day and 30–50 day scales from eastern part of the trough over the Bay of Bengal across the monsoon trough region. When a monsoon depression moves into the Rajasthan region, moisture is fed into the entire vertical column and tall clouds form, resulting in considerable rainfall over the region. The region of 'heat low' now becomes a region of heat source due to release of latent heat and moisture sink due to moisture convergence accompanying the weather disturbance. This is a transient phenomenon, which is replaced by the normal heat law pattern in about 3–5 days and the desert region again becomes a heat sink.

Regional and global and circulation cells and the Indo-Saharan desert climate

Two important vertical cells, viz. the Hadley cell in the south-north direction and the Walker cell in the east-west direction, have crucial links with the desert climate over the Indo-Saharan region. Hadley cell is primarily responsible for the year-round aridity as the desert regions fall in its downward limb. Even in summer monsoon season when the traditional Hadley cell has shifted north of India, the desert regions are mostly dry except during occasional travel of the monsoon disturbances to extreme western parts of India. This is as a consequence of two factors. Firstly, Das[58] showed the existence of a regional east-west vertical circulation in which deep ascent occurs over eastern India and the compensatory descent occurs over the Thar desert. This regional cell oscillates on sub-seasonal scale as discussed in the earlier paragraphs. Secondly a global scale Walker circulation prevails with ascent centred over eastern India and descent over the Indo-Saharan desert region in the west. This is supported by divergence at 200 hPa over the Tibetan high region and convergence in the adjoining mid-Pacific trough in the east and mid Atlantic trough in the west on the planetary scale. On interannual scale this global Walker cell along the summer ITCZ belt in NH is influenced by the ocean atmosphere coupled system in the equatorial eastern Pacific, commonly known as the ENSO phenomenon. During the warm phase of the ENSO, the Tibetan high at 200 hPa is displaced more eastward. A zone of convection migrates eastward from Indonesia to the central Pacific and the large-scale convective activity is decreased over India and adjoining tropical belt. This results in major monsoon drought over SE Asia, India, Somalia and sub-Saharan regions.

Numerical atmospheric general circulation experiments on desert climate

Numerical experiments

ACGMs have been extensively used in the last two decades to understand the process of desertification on regional scale. The premise for such studies is on three approaches, all of which have links with the energy balance principle, as applied to deserts. Deserts are regions of net energy deficit, because of high albedo, high long-wave emissions, high sensible heat and low latent heat contribution in the desert–atmosphere system. Otterman[59] and Charney[60] proposed hypothesis for the desertification which was based on the increase in albedo of the deserts by human activity such as overgrazing and loss of vegetation cover with consequent more radiative energy loss and decrease in temperature of the desert environment and reduction in convective overturning, resulting in enhancement of the desert system. The second hypothesis was tested by the numerical experiments of Walker and Rowntree[61], Shukla and Mintz[62] and several other workers since then. It is based on the vegetation–atmosphere interaction involving the role of soil moisture and evapotranspiration in modulating the energy balance, rainfall, temperature and moisture fields. A third approach was suggested by Sud and Smith[63] and Sud *et al.*[64] which rested on changes in surface roughness due to decrease in vegetation affecting the surface momentum balance and hence the efficiency of heat and moisture transports in the desert–atmosphere system.

All the three approaches involve biogeophysical mechanisms and are linked with land–vegetation–atmosphere or the land surface processes. Although some observational studies support the above approaches, they can best be tested by employing controlled and anomaly GCM experiments through sensitivity studies. As such a spate of such experiments on all the hypotheses have been performed by different numerical modelling groups since the first work by Charney *et al.*[65] and Chervin[66], using different parametrization schemes for the land surface processes, some of which even include separate biospheric models. Good reviews on the subject are provided by Dickinson[67], Rowntree[68], Sud *et al.*[69] and Dirmeyer and Shukla[70]. Many numerical modelling studies have been carried out to understand regional droughts such as Sahellian, north American Great Plains, Australian and South African droughts on the above three approaches since 1970s. In a review of 11 such studies, Mintz[71] concluded that soil moisture had a stronger impact on model-simulated climate than did albedo or surface roughness. Some of the models have been used to understand the role of biogeophysical processes on the monsoon rainfall in western Indian desert and the results are mixed[64,72,73]. This may be, among other factors, due to the fact that the numerical models have yet to produce an acceptable simulation of the monsoon rainfall of India and hence at this stage may not be very appropriate tools for sensitivity studies on monsoon. Recently Fennesey and Shukla[74] have provided a review of the role of soil moisture anomaly studies on precipitation and temperature anomalies in the mid-latitude belt of USA.

There is a variety of observational evidence supporting and even contradicting the expectations based on biogeophysical feedbacks. Recent observational studies have pointed to reduced importance of albedo feedback on desertification and have challenged Charney's hypothesis by showing that surface warming instead of surface cooling occurs during prolonged droughts. Besides they also claim that Charney's hypothesis does not explain synchronous occurrence of major droughts over several regions such as in Sahel, Kalahari, Australian and Thar deserts. It also does not explain the termination of such droughts. Thus albedo model is now considered as interesting but unproven. On the other hand, soil moisture mechanism for desertification by bringing changes in the hydrological parameters through vegetation–atmosphere interactions, has gained importance. The major factor for the synchronous occurrence of droughts on inter-annual and inter-decadal scales is considered to be the coupled ocean–atmosphere ENSO phenomenon. However, it cannot be ignored that human activity has pronounced influence on the local scale desert climate through accelerated soil erosion, deforestation and loss of vegetation and soil organic matter by over-grazing and over-exploitation of the soil resource. In areas without irrigation facilities, desertification can lead to increased temperature and reduced rainfall. Irrigation can reverse these effects, as it has happened in the Indira Gandhi Canal command area, but it is producing increased salination of the soil.

Numerical experiments on expansion of desert climate and global climate

As deserts are important sub-component of the global climate system, there is a concern that expansion of deserts may impinge on the global climate. Observational evidence is mounting that desertification has been occurring extensively over the world for the last several decades[75–77]. In order to specifically address the problem of enhancement in desert areas and their possible impact on regional global climate, Dirmeyer and Shukla[78] have used a GCM and the realistic land surface properties with present day extent of deserts (control run) and doubling their extents (anomaly run) over all the continents. The deserts were extended by altering the land surface properties and type of vegetation over the present day deserts and their margins. The double desert case represents an extreme scenario of desertification which might ensue as a result of natural and anthropogenic causes. The results of the control and anomaly runs for 10 years were compared and showed the following aspects prominently:

(i) Significant cooling over much of the tropics and sub-tropics and the cooler air in the double desert case covered an area nearly six times the size of the current deserts. This impact is, therefore, global in nature.

(ii) Rainfall generally, but invariably, decreases over desertified areas. Over Africa the decrease is largest (20 to 60%). Over the leading edge of the Indian monsoon region such as the Gangetic plains and adjoining Myanmar and China significant decrease in rainfall (about 10%) is also noticed. Some increase in rainfall is noticed over Peninsular India, Sri Lanka and Malaysia. Similarly evapotranspiration anomalies are larger over Africa than over South Asia. Lower response over South Asia is perhaps due to the fact that this core region of the monsoon is influenced by warm SST in Western Pacific and Bay of Bengal regions as well as by the elevated heat source over the Tibetan region.

The results of this experiment more or less followed Charney's hypothesis with regard to cooling over the deserts. The experiment of Dirmeyer and Shukla[78] no doubt points to potential danger of decreased rainfall over much of the tropics and sub-tropics in response to doubling of the present extent of the deserts.

Concluding remarks

We have discussed many aspects of desert climate based on the work of many researchers. Desert climate is harsh for human habitation as these ecosystems are highly responsive to climate variability. However, man has lived in several arid and semi-arid areas for thousands of years in harmony with nature, particularly in the Thar desert which is unique for it lies on the western margin of the Indian Summer Monsoon System and where the population is fairly high. Population pressure and increasing exploitation of the vegetational and soil resources in desert lands are raising serious doubts among experts whether nature can sustain such over-exploitation resulting from human greed. As desertification and desert climate are intimately linked, several science and technology measures would benefit sustainable development of the arid and semi-arid regions and some of them are:

(a) Provision of natural resource information to local people and policy makers. For India such an information system is being developed by DST and the Department of Space in collaboration with NRSA.

(b) Enhancement of regional climate monitoring network.

(c) More numerical modelling studies and their coupling with empirical and observational studies such as land surface field experiments.

(d) Application of seasonal monsoon forecasting for contiguous arid and semi-arid regions separately rather than the present system which addresses India as a whole.

Desert climate is an integral sub-component of the global climate. However, if desertification is allowed to go unabated, numerical modelling studies point to a scenario that it would impact on the climate of regions farther away from deserts themselves. This would be an unfortunate event for the modern world civilization which is based on intensive development culture and over-consumption. There is a silver lining that the problems posed by desert and threatened desert margin climates can be tackled adequately by combining modern science and technology with the traditional rational knowledge of the inhabitants of the regions, who have learnt to live for many generations in harmony with their rather harsh natural environment. They have used its fragile resource on sustainable basis till now with wisdom born out of experience. Science and technology can surely help them to do it for future too.

ACKNOWLEDGEMENTS. I thank several individual scientists in various organizations in India and abroad who expeditiously provided their publications for reference. I also acknowledge the support provided by the National Centre for Medium Range Forecasting, New Delhi, the IITM, Pune and the Institute for Global Environment and Society (IGES), Maryland, USA in the preparation of this paper.

Role of remote sensing in resource management for arid regions with special reference to western Rajasthan

George Joseph

Space Applications Centre, Ahmedabad 380 053, India

The arid region of western Rajasthan is about 20.87 Mha covering 85 blocks of 12 districts of Rajasthan which constitutes 61% of the state. About 38% of the total population of the state with a density of 84 persons per sq km area lives in the arid region of Rajasthan. The constantly increasing human and livestock population is putting tremendous pressure on the available natural resources. The major problems of the region are: scarcity of water, frequent droughts, land degradation, deteriorating pasture lands and advancement of desert. Therefore, it is essential to explore newer sources of resources as well conserve the existing natural resources. Optimal management of natural resources is of utmost importance in today's context to increase the production of food grains, fodder and develop water resources for meeting the demand. Remote sensing provides timely, reliable and spatially comprehensive data on various natural resources for effective planning, implementation and monitoring. Some of the natural resources problems of the western Rajasthan, use of remote sensing techniques and role of current and future Indian remote sensing programme are highlighted in this paper.

ARID zone in India covers about 39 million hectare (Mha) area constituting about 12% area of the country. It covers 32 Mha as hot and 7 Mha as cold arid zone. Twelve districts in western Rajasthan covering 20.87 Mha fall in the hot arid zone, constituting around 61% of the total area of the state. These districts are Barmer, Bikaner, Churu, Ganganagar, Hanumangarh, Jaisalmer, Jalore, Jhunjhunun, Jodhpur, Nagaur, Pali, and Sikar and together constitute 85 blocks. According to the 1991 census about 38% of the total population of the state with a density of 84 persons per sq km area lives in the arid region. The livestock population is around 25 million (1987–88) with a density of 120 per sq km. This makes it one of the most densely populated deserts of the world. The constantly increasing human and livestock population is putting tremendous pressure on the available natural resources.

The western Rajasthan has typical characteristics. They are (i) mean annual rainfall of about 310 mm, (ii) about 50% of the region has plain lands without stream network, (iii) about 30% of the region has slopy lands with stream network mainly in the Luni basin, (iv) about 20% of the region is covered under Indira Gandhi canal command area.

The main problems of the region are: (i) low and erratic rainfall, frequent droughts, (ii) scarcity of water, (iii) available groundwater resources is also not sufficient since it is brackish/saline at many places and found at greater depths with low discharge, (iv) soil is less productive, (v) water logging problem in Indira Gandhi Nahar Project areas, (vi) wind erosion causing high erodibility of sandy soil, (vii) deteriorating pasture lands and (viii) advancement of desert.

Remote sensing is the science of making inferences about material objects from measurements, made at distance, without coming into physical contact with the objects under study. In this context, any force field – gravity, magnetic or electromagnetic, could be used for remote sensing, covering various disciplines from astronomy to laboratory testing of materials. However, currently the term remote sensing is used more commonly to denote identification of earth features by detecting the characteristic electromagnetic radiation that is reflected/emitted by the earth surface.

Satellite remote sensing provides synoptic view, enabling one to understand the inter-relationship between various features observed. In addition, remote sensing satellites cover the same area repetitively, making it possible to understand and monitor changing physical processes. Availability of data at different spatial resolution provides information at macro level and micro level. Microwave remote sensing provides all weather capability. Thus satellite remote sensing provides timely, reliable and spatially comprehensive data on various resources for their exploration, monitoring and effective management.

The data received from the satellites can be analysed using computer or by visual interpretation. For visual interpretation the data is converted into photographic images. The photographic images are usually generated using green, red and near infrared (NIR) assigning blue, green and red respectively. This is called False Colour Composite (FCC) since it does not depict true colour, as the information of the blue band is missing. Since for the vegetation the reflectance in NIR is higher, the vegetation appears red in the FCC. Figure 1 shows the imagery of western Rajasthan produced by the IRS-1C WiFS camera, with the district boundaries overlaid. It depicts vegetation biomass in red colour wherein good vegetation is seen in Ganganagar, part of Hanumangarh, east Nagaur, Jhunjhunun, Sikar, Pali and Jalore districts. Medium vegetation is seen in central part of Jaisalmer and west part of Jodhpur districts. Low vegetation is seen in part of Bikaner, east Barmer and Churu districts. No vegetation/dry area are in parts of Jaisalmer, Barmer, Bikaner, Churu and Hanumangarh districts.

Table 1 gives some of the major problems in the region of Rajasthan and possible applications of remote sensing to help in evolving suitable strategy for their management. The details of application of remote sensing in tackling some of the natural resource problem areas are discussed here.

Water resources

The western Rajasthan faces acute shortage of potable water and village women have to fetch water from many kilometers away to meet domestic requirements. Sixty to sixtyfive per cent of western Rajasthan has saline to highly saline groundwater with the TDS (total dissolved salts) content ranging from 2000 ppm to 20000 ppm. In addition to problem of obtaining potable water, deterioration of land due to the use of poor quality groundwater for irrigation is causing serious concern.

Remote sensing aids quick identification of groundwater prospective zones. Some of the indicators of groundwater prospective zones are lineaments, lineament intersection, palaeochannels and valley fills. During the drought of 1986, hydrogeomorphological maps on 1 : 250,000 scale for the entire state using Landsat TM imagery were prepared. These maps show hydrogeomorphological units and the related groundwater prospects. A typical hydrogeomorphological map of Shahbad Tehsil of Baron district in Rajasthan is given in Figure 2.

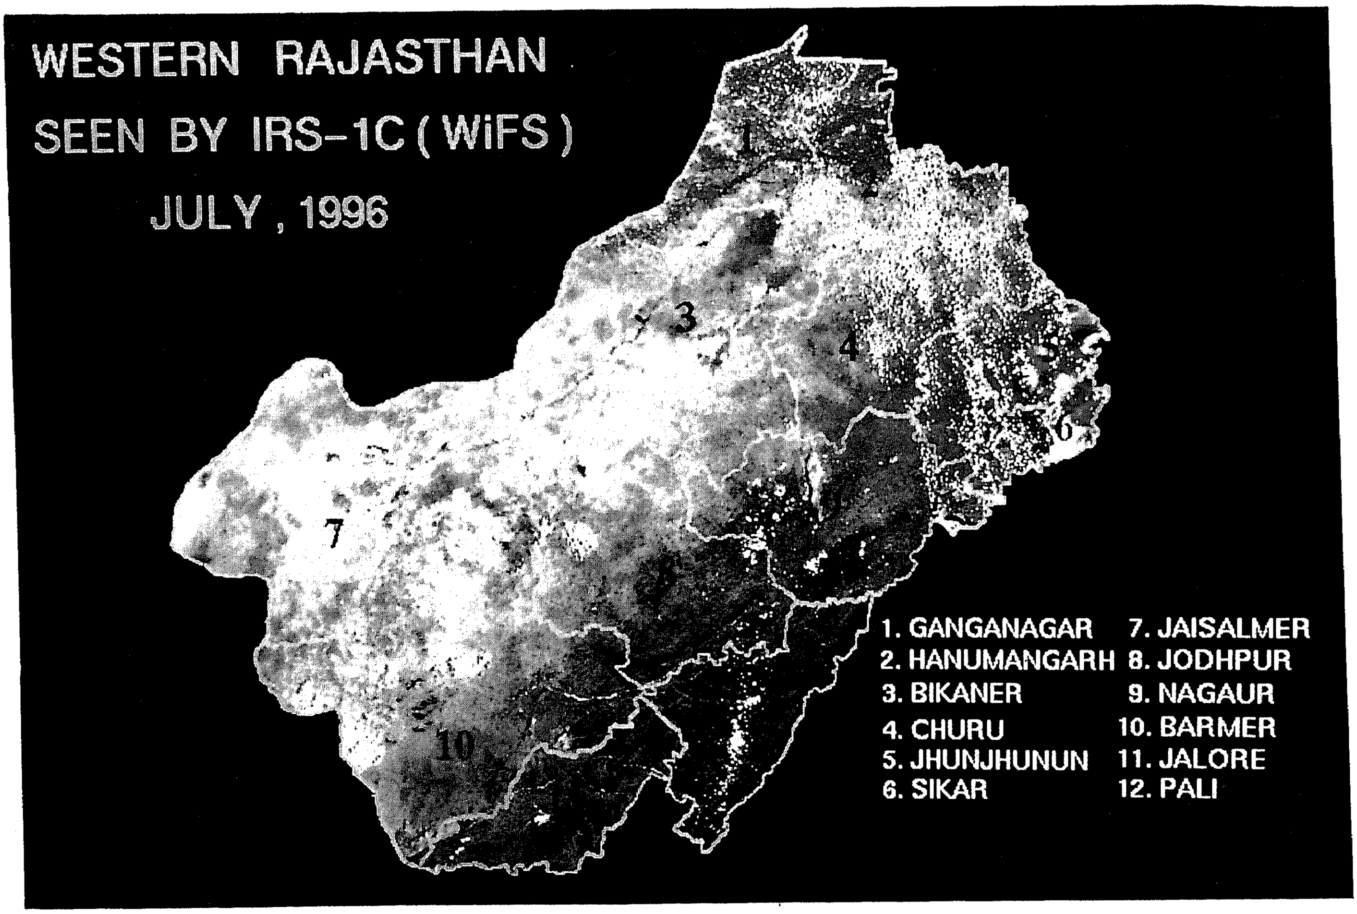

Figure 1. IRS-1C WiFS view of western Rajasthan with district boundaries overlaid.

Table 1. Major resource management problems in arid region of Rajasthan

Problems	Remote sensing potential
Scarcity of water	Identification of groundwater prospective zones, Sites for recharge structures
Frequent droughts	Assessment of drought conditions through NDVI
Advancement of deserts	Monitoring of sand drift/movement
Land degradation	Monitoring wastelands, Water logged area, Land use/cover, Impact of mining
	Prioritize erosion prone area for soil conservation measures
Deterioration of pasture lands	Grassland inventory, condition assessment and monitoring

The map shows spatial extent of various hydrogeomorphological features. Good to very good groundwater prospects are represented by valley fills, lineaments and buried pediment in sandstone. These maps provided the 'first cut' information for carrying out follow-up hydrogeological and/or geophysical measurements for pinpointing sites for exploratory drilling. Detailed mapping for Jaisalmer and Bikaner districts on 1 : 50,000 scale has been carried out using IRS LISS-II and partially SPOT images. Currently under the Integrated Mission for Sustainable Development, detailed action plans for water resources development like sites for water conservation and harvesting have been generated for many districts in the western Rajasthan, where the satellite data and field data have been integrated. Efforts have also been

made to explore potentials of radar (ERS-1 SAR) data in identification and mapping of buried channel and relict valleys near Jaisalmer for groundwater prospecting. Also a synergistic methodology of integrating optical with microwave data to reconstruct the palaeo drainage network of western Rajasthan is being attempted.

To sustain the groundwater potential it is essential to recharge the groundwater. The recharge is achieved primarily by three methods, viz. i) spreading, ii) induced recharge, iii) injection. Remote sensing provides useful inputs for siting various recharge structures, through thematic maps on hydrogeomorphology, land use/cover, surface water bodies, slope, etc. The main guiding factor is location of a permeable zone. Some of the indicators, which can be deciphered from the remote sensing images, are crossing zones of dykes over streams, low drainage density, higher lineaments intensity, confluence of channels, valley fills, palaeochannels, etc.

Drought assessment and monitoring

Drought in western Rajasthan is a regular phenomenon. Generally, mild and moderate agricultural drought occurs in the entire region, while the Jaisalmer region experiences severe drought conditions. The climatologists have estimated that the drought occurrence probability in western Rajasthan is less than 20%, implying that, on an average, one in every five years is expected to have large rainfall deficit. The sand and dust movements generally assume serious proportions in the years following the drought year, when the vegetation cover is minimum. Sand flux rates of up to 150 kg per square meter are common during the peak of dust storm activity. Generally May and June are the periods of strong wind when sand movement causes problems for human settlements and transportation networks. The average wind speed during June is more than 25 kmph in the western part, while in the eastern part it is between 10 and 15 kmph. These natural climatological conditions have impact on acute water shortage and land degradation.

Satellite data has proved to be extremely useful in monitoring drought. Starting from mid 1989, the National Remote Sensing Agency (NRSA) has been issuing fortnightly drought bulletins based on the analysis of the NOAA–AVHRR data for the entire country including Rajasthan. The bulletin contains maps on vegetation index, comparative greenness and district-wise assessment of the drought like normal, mild, moderate or severe. In the present day context IRS-1C data with high spectral/spatial resolution can even provide village level severity assessment and thereby determine the quantum of relief assistance and crop insurance.

Advancement of desert

The western Rajasthan suffers from destabilization of dune systems due to high wind erosion, excessive grazing by livestock and cattle coupled with other activities like road building, canal excavation, quarrying, ploughing besides deforestation. It is estimated that nearly one third of the cultivated lands is severely affected by the problem of sand drift, while another one-fourth is moderately affected. The mean soil loss in the deeply ploughed fields for example in an unusually windy year of 1985 was estimated to be 2837 tonnes/ha (ref. 1). The spread of desert towards east and north east has endangered the productivity and fertility of soil cover. A regular monitoring is therefore required for the above activities so that suitable remedial measures can be suggested.

Change detection on the fringe of the desert region in Rajasthan has been carried out using multi temporal satellite data and digital analysis techniques. This has brought out that the desert is spreading through something like twelve large size gaps in the central and northern Aravalli hill ranges. This study thus speculates that an area of about 160 km^2 every year is engulfed by the advancing desert. Measures to check the spread of desert have been suggested[2].

Under a joint study by CAZRI and RRSSC, Jodhpur a number of sites have been studied to identify the stability of sand dunes using multi-temporal satellite data which causes shifting of sand.

Grassland inventory and monitoring

The region receiving mean annual rainfall of 200 mm and less is incapable of supporting agriculture on its own. It can sustain animals on its natural vegetation comprising of shrubs and grasses. Animal husbandry replaces agriculture in this region, which is crucial to the economy of the region. Therefore, the natural grasslands are one of the most precious natural resources. Amongst the other grasses, Sewan (*Lasiurus sindicus*) is the dominant perennial grass. There are nearly six million ha of Sewan-dominated open pasture lands. These grasslands are being degraded either due to impoverishment of the useful species or indiscriminate grazing. Nearly 24 and 44% of the pasturelands are in desertified and highly degraded states respectively.

Satellite data have been used to carry out inventory and monitoring of the areas under Sewan grass. Using multi temporal IRS LISS-II data of 1988 and 1989 and image differencing techniques, areas under four categories of Sewan grasslands in Jaisalmer, Bikaner and parts of Jodhpur district could be estimated and a reliable inventory of this crucial resource could be made.

Locust warning and surveillance

Locust breeding is one of the major problems in western

Rajasthan as it poses threat to the standing agricultural crops and plantations. Moist sandy soil of the desert and flush of desert vegetation during monsoon creates optimal conditions for fast locust breeding and development.

In the later part of 1989 there was a sudden build up of locust swarms from Pakistan to India. The Locust Warning Organization of the Directorate of Plant Protection, Govt of India used IRS and NOAA data to generate five green biomass levels within the sparse desert vegetation. Multidate imagery helped to monitor and launch selective control measures in an area of 200,000 km^2 (ref. 3).

Land degradation *vis-à-vis* IGNP

In the canal command area under Indira Gandhi Nahar Pariyojana (IGNP), Stage I a mean rise in water table of more than one metre per year has been recorded. This is leading to the problem of land degradation as the productive land is getting converted into water-logged and salt-affected areas.

Environmental impact of the Indira Gandhi Canal in the command area has been monitored using multidate IRS LISS II and NOAA–AVHRR data. The analysis of satellite data helped in monitoring land use changes, mapping and assessing the progress of afforestation programme along the canal network, monitoring the extent of waterlogged areas, inventory of irrigated crop, assessing crop water demand and monitoring crop growth patterns. Figure 3 shows the Rawatsar area satellite imagery of October 1975 and October 1995. The distinct red colour in October 1995 image clearly depicts increased cropped area as compared to October 1975 image. The waterlogged areas are seen in 1995 image as black and bluish patches. The cropped area has increased by more than 50% from 1975 to 1995. However, waterlogged area has also increased due to excess irrigation and poor drainage. Thus remote sensing can be used to monitor the change during every cropping season and the information is vital for proper land use planning and corrective measures to be taken.

Wasteland inventory

Large areas in the arid region are under wasteland category. The development of wastelands not only helps in improving the land productivity and socio-economic conditions of the region but also helps in re-establishing the ecological balance.

Under the National Wasteland Mapping Project, wasteland mapping at 1 : 50,000 scale using Landsat TM data has been carried out for three districts namely Churu, Jodhpur and Pali. Various categories of wasteland like gullied/ravinous land, upland with or without scrub, land affected by salinity/alkalinity, sandy areas, mining-industrial wasteland, under-utilized/degraded notified forest land, degraded pastures/grazing land, barren rocky/stony wastes/sheet-rock areas, and steep sloping areas have been mapped. It has been estimated that about 60.9, 30.6 and 26.6% of the total area of Churu, Jodhpur and Pali districts respectively is under wasteland. Depending upon the nature of the wasteland categories at village level, reclamation measures have been suggested.

Soil erosion studies

Soil erosion seriously affects the productivity of land. Life of a reservoir is dependent on the soil erosion in the catchment areas. It is essential to characterize the watershed according to intensity of erosion-prone areas, so that soil conservation measures can be taken on priority in those areas which are highly prone to erosion. For this purpose thematic maps such as land use/cover, geomorphology, slope and soil are prepared using remote sensing and conventional data. Integrating these maps and suitable models, it is possible to categorize watersheds into various severities of erosion. A classified image showing severity of soil erosion for Neem Ka Thanna tehsil of Sikar district is shown in Figure 4. High priority watersheds, shown in pink colour, represent hilly areas having steep slopes and degraded forest lands. Similar work has also been carried out for Kishanganj, Shahbad, Devli and Nadoti blocks of Baran, Tonk and Sawai Madhapur districts respectively.

Agroclimatic-zone based land use planning

A systematic district-wise land use mapping on 1 : 250,000 scale has been carried out using IRS LISS-I data. These maps show Level I and II categories. Using two-date imagery, acreages under kharif and rabi crops have been estimated. The information thus generated is being extensively used for agroclimatic-zone based land use planning. Presently 49.4% of the total area is under cultivation, 35.5% area is under cultivable wastes and fallow lands, 4.1% area is under permanent pasture, 1.8% area is under forest and 9.2% area is either barren or settlement[1].

Mineral prospecting

The occurrence of minerals is not random, i.e. mineralization is always confined to specific geological environments and various guides for mineral prospecting are utilized. Satellite data indicates, for e.g., i) zones of crustal weakness, e.g. faults, fractures, joints, folds, shear zones, etc. which serve as passage ways for mineralizing solutions, ii) tonal anomalies – alteration zones, vegetation anomalies, etc. and, iii) major rocks types and landforms.

Important industrial minerals and rocks occurring in the western Rajasthan are the building stones (like marble, limestone, sandstone and granite), limestones of cement, flux and chemical grades, various types of clays for ceramics, common salt, bentonite and Fuller's earth, gypsum/gypsite and phosphorite, lignite and wolframite.

Although there has been limited use of satellite data for mineral exploration it has been observed that gypsite (earthy porous gypsum aggregate with sand, clay and calcareous matrix) occurs in low-lying playa deposits and in palaeochannels, which can be mapped using satellite data. Rajasthan accounts for about 90% of the total production of gypsum in the country. In the western parts of the Jaisalmer district the Khuiala and Bandah limestone deposits occur. It has been estimated that about 2500 million tonnes of chemical and flux grade limestone occurs in the region. In this region recently ERS-1 SAR data could detect shallow sand buried limestone deposits. The structural and geomorphological information in the Jaisalmer district has provided useful clues to the oil and natural gas exploration.

Integrated mission for sustainable development

Realizing the importance of adopting an integrated approach, and recognizing the mutual inter-dependencies of natural resources, the Department of Space, at the behest of the Planning Commission, Govt of India has taken up a major programme 'Integrated Mission for Sustainable Development (IMSD)', along with various state and central government agencies. Participation of voluntary agencies and the local people is an important component of this programme. Under this mission, it is proposed to undertake remote sensing-based integrated land and water resources studies for 174 problem districts of the country. The major goal of this mission is to generate locale-specific plans by integrating natural resources information generated from satellite data in conjunction with socio-economic data to meet the needs of the local people for sustainable development of the region. The goal when translated into executable tasks results in the following:

i) Analysis of socio-economic, demographic data of the region to find the felt/perceived development needs of the region.
ii) To generate various thematic maps on natural resources and integrate them to identify homogeneous units of land parcels for suggesting measures for soil conservation, water resources development, agriculture/horticulture, and fodder development.
iii) To critically assess the existing infrastructure of the region and to arrive at development schemes (suitable sites for location, alternate strategies, etc.).

The Regional Remote Sensing Service Centre (RRSSC), Jodhpur along with State Remote Sensing Applications Centre (SRSAC), Central Arid Zone Research Institute (CAZRI), and other Non-Government Organizations (NGOs), is carrying out IMSD studies in ten districts, viz. Barmer, Bikaner, Churu, Nagaur, Jalore, Jaisalmer, Jhunjhunun, Jodhpur, Sriganganagar, Sikar and Pali of western Rajasthan and Jaipur, Dausa, Ajmer, Bharatpur, Sawai Madhopur, Banswara, Dungarpur in east and south Rajasthan. Besides this, eleven blocks under special IMSD study have been completed. These are Kishanganj, Shahbad, Ramganj, Mandi, Sangod, Kherwara, Garhi, Nadoti, Devli, Dag, Dungarpur and Masuda.

Indian Remote Sensing Programme

Indian Space Research Organization (ISRO) successfully developed and launched the operational first generation remote sensing satellite IRS-1A in March 1988 and the follow-on IRS 1B in August 1991. These satellites carried two imaging payloads operating in four bands in the 0.45–0.86 μm region. One of the payloads (LISS-I) has the geometric resolution of 72.5 m and a swath of 148.48 km and the other camera LISS-II has a geometric resolution of 36.25 m. Two LISS-II cameras were displaced laterally so as to provide a combined swath of 145.48 km with an overlap of 3 km (ref. 4). A third operational remote sensing satellite IRS-P2 was launched in October 1994 using the Polar Satellite Launch Vehicle (PSLV) developed by ISRO. IRS-P2 carried a modified LISS-II camera.

Data from these remote sensing satellites have been extensively used for various applications towards national development. Starting from field experiments to district level studies, currently a number of projects are being carried out covering the entire/most part of the country on an operational mode. Groundwater targetting, Regional Geological Mapping, Flood Mapping, Forest Mapping, Land Cover Mapping, Wasteland Mapping, Snow Area Mapping, Crop Production Estimation, Watershed Characterization, Coastal Zone Mapping, etc. are some of the national level projects taken up. These have been taken up in 'mission-mode' under the umbrella of a programme called Remote Sensing Applications Mission (RSAM). The Integrated Mission for Sustainable Development (IMSD), wherein various themes using remote sensing and socio-economic and other data are integrated to find out optimum developmental plan opens new vistas to apply remote sensing technology for practical application.

The IRS-1C launched in December 1995 carries three distinct and mutually complementing imaging payloads which enhance the capabilities of IRS-1C as compared to IRS-1A/1B in terms of spatial, spectral and temporal resolutions. Another remote sensing satellite IRS-P3 was launched on March 1996 with PSLV carrying a Wide Field Sensor similar to IRS-1C, with an additional band in SWIR and an ocean colour monitor, developed by DLR (Germany) for earth observation.

The IRS-1C has a PAN camera with 5.8 m resolution, a multispectral camera (LISS-III) with 23.5 m resolution in visible and near infrared region and 70.5 m in the shortwave infrared region. The PAN camera covers a ground swath of 70 km which is steerable up to ±26° from nadir in the across track direction. This off-nadir viewing provides the capability to acquire stereoscopic pairs from two different orbits and an ability to revisit any given site with a maximum delay of five days. Currently the IRS-1C, PAN camera is the highest spatial resolution civilian earth observation system.

A Wide Field camera (WiFS) has a spatial resolution of 188 m and covers a swath of 804 km. This wide swath coverage results in a repeatable observation of the same ground location after every 5 days. The WiFS operates in the B3 and B4 spectral bands of LISS-III.

Application potential of IRS-1C

The payloads of IRS-1C complementing each other for earth viewing have immense application potential which was hitherto not possible. Some of the unique advantages from the applications point of view are:

- Monitoring vegetation, snow and water body more frequently (5 days) and mapping them at regional scale
- Improved identification/discrimination of vegetation types/crops in view of higher spatial resolution (VNIR 23 m) and SWIR band
- Moisture stress detection especially by the use of SWIR band
- Large scale mapping using merged LISS-III and PAN data
- Stereo capability and frequent viewing using PAN
- Availability of data at different spatial resolutions from a single platform (acquired simultaneously) suitable for multistage/sampling approach.

Using the data available so far from IRS-1C, a host of applications have been demonstrated.

Future Indian Remote Sensing Satellites

IRS-1B, IRS-P2, IRS-P3 and IRS-1C are presently in use providing information on earth resources to various user agencies on an operational basis. IRS-1D, which is similar to IRS-1C, is planned to be launched in 1997. Other approved space systems for future include Oceansat-1 carrying an ocean colour monitor and a multifrequency radiometer, a cartographic satellite with fore and aft viewing with about 2.5 m resolution and a satellite system tuned to meet many of the needs for agricultural applications.

Future systems being conceived include Oceansat-2 carrying various sensors for ocean applications such as scatterometer, altimeter and radiometer, satellites for climate studies and high resolution imaging systems for updation of large scale maps.

All these missions providing data at higher spatial and temporal resolutions along with the technological advances made in processing and modelling techniques including GIS should be revolutionizing the field of remote sensing applications in the country. It is for us, the user community of scientists, policy and decision makers, planners and implementation level officers of various government and non-government agencies to make full use of this opportunity for national development.

Isotope hydrology studies on water resources in western Rajasthan

S. M. Rao and K. M. Kulkarni

Isotope Division, Bhabha Atomic Research Centre, Trombay, Mumbai 400 085, India

Environmental isotope studies in the Jalore and Barmer areas show that deep groundwaters have depleted ^{2}H and ^{18}O compared to the present day precipitation and have negligible tritium. Radiocarbon levels indicate groundwater ages ranging from 2400 to 7400 BP. Shallow groundwaters, on the other hand, show bomb tritium indicating some component of modern recharge. Studies on the effect of the Indira Gandhi canal on groundwater environment helped in differentiating the areas waterlogged by canal seepage and those affected by return flow of irrigation. A study on the buried channel of the legendary 'Saraswati' river in Jaisalmer district indicates shallow waters are old with ^{14}C content of 54.9 pMC to 58.8 pMC (uncorrected ages: 4950 to 4400 BP) with a velocity of about 20 m/a.

ARID zones pose special problems to hydrologists anywhere in the world. Conventional techniques have methodological constraints[1]. Some are: a) paucity of rainfall data due to irregular distribution in time and space and frequently disastrous and ungaugable storm events, b) untested extrapolation of the estimates of potential evapotranspiration to arid regions, and c) limitations on the use of geoelectric profiles due to dry shallow horizons and deep saline formations.

On the other hand, experience in the applications of isotope techniques in India and elsewhere indicated that the techniques are better suited to arid zones than to any other geographical situation. The reasons are: 1) The isotopic composition (^{2}H and ^{18}O) of rainwaters depends on the temperature of condensation, altitude and intensity of rainfall. This results in different isotope signatures for different rain events, particularly in the arid and semi-arid regions. 2) Evaporation, unlike condensation, causes kinetic fractionation of ^{2}H and ^{18}O and provides an identifiable isotopic characteristic. 3) Paleowaters from earlier pluvial episodes have depleted ^{2}H and ^{18}O, insignificant tritium and low levels of ^{14}C in dissolved bicarbonates. Radiocarbon helps in the age-dating of paleowaters.

In addition to the above, it is possible to tag a layer of soil moisture in the unsaturated zone with a suitable radioactive tracer like tritiated water or ^{60}Co labelled $K_3Co(CN)_6$ (ref. 2) and follow its movement to evaluate rainfall recharge.

Recharge to shallow aquifers is the subject of great interest to groundwater management in arid areas since modern recharge to deep groundwater is relatively rare.

Isotopes help in answering such questions as

- Is there modern recharge?
- If so, what is the recharge process; direct infiltration of rainwater, contribution during flash floods, return flow of irrigation, etc.?
- If not, when was the aquifer last recharged?

Some typical isotope studies carried out in western Rajasthan are discussed briefly in the following sections.

Jalore district

An environmental isotope study was undertaken to investigate groundwater recharge in the Jalore area of Rajasthan. The study area located in Jalore district of southwestern Rajasthan (Figure 1) is arid and receives mean annual rainfall of 380 mm. The area is covered extensively by alluvium. Presence of sand dunes is a common feature in the area, especially in the western part of the study area. The surface drainage consists of Sukri river, a tributary of the Luni river system, which is ephemeral in nature and flows towards southwest, i.e. towards the Rann of Kachchh in Gujarat.

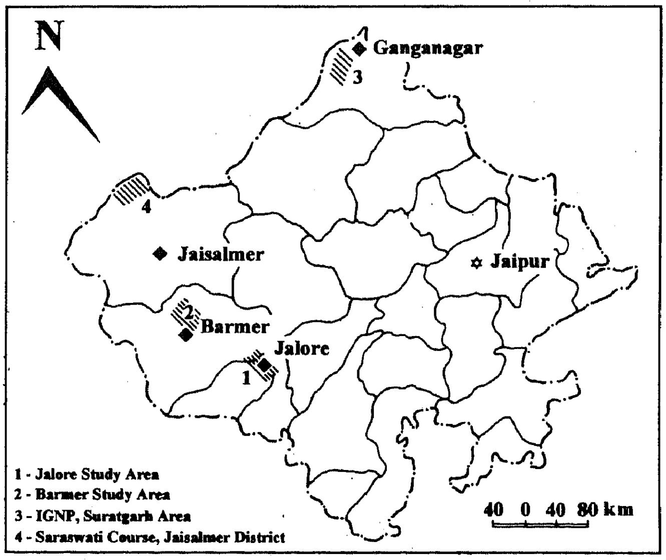

Figure 1. Locations of isotope studies in western Rajasthan.

The younger alluvium is mostly present along the course of Sukri river and comprises unconsolidated to semi-consolidated coarse to fine sand and gravel. The older alluvium of sub-recent to the Pleistocene age consists of semi-consolidated to consolidated coarse to medium sand with clay lenses, caliche and rock fragments. Tertiary sediments, consolidated clays with sand and shale fragments, are encountered at depth in the western as well as southwestern portion of the study area.

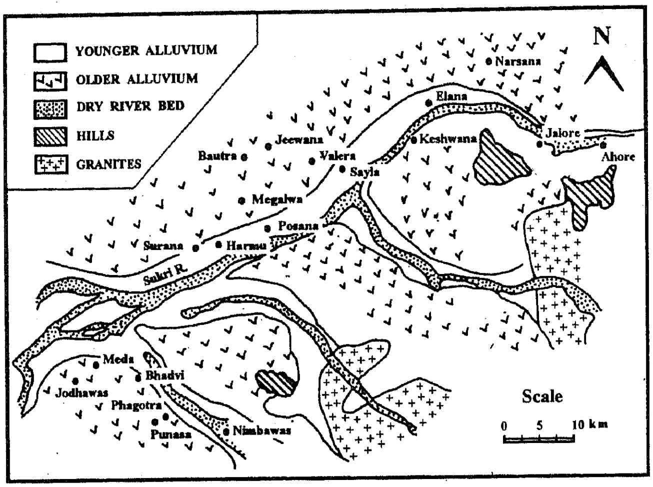

Figure 2. Jalore study area – sample locations (note: Bhadrajun (D14 in Table 1), NNE of Narsana not shown in Figure).

Study of subsurface geology based on borehole data shows that depth to basement increases abruptly west of Sayla probably due to presence of a fault. Sukri river also flows along a NE–SW trending fault. A number of smaller faults are also suspected in the area.

Shallow groundwater mostly occurs under phreatic conditions. Conditions changing from confined to artesian flowing type are observed in the southwestern part. An artesian flowing well is located at Jodhawas which mainly taps the Tertiary aquifer. Groundwater flows towards west-southwest.

A number of samples from shallow (depth < 50 m) and deep (depth > 150 m) wells were drawn from various places (Figure 2) for environmental isotopes as well as major ion chemical analyses[3]. The relevant results are given in Table 1.

In general, fresh, shallow groundwater in the northern part of the study area is of Ca–HCO_3 type. Shallow groundwater along the river course and fresh, deep groundwaters at Punasa and Sayla are of Na–HCO_3 type indicating base exchange. Majority of brackish groundwaters, shallow as well as deep, are of Na–Cl type. Electrical conductivity (EC) of shallow groundwaters ranges from 960 µS/cm to 5300 µS/cm and that of deep groundwaters varies from 1200 µS/cm to 5400 µS/cm.

Table 1. Isotope and other relevant data of samples from Jalore district, Rajasthan

Sample identity	Place	Depth of well (m)	Electrical conductivity (µS/cm)	Chloride (mg/L)	δ^2H (‰)	δ^{18}O (‰)	^{3}H (TU)	^{14}C (pMC)
Deep wells

Figure 3 shows the plot of δ^2H versus depth of samples from the study area. It could be seen from the plot that the three different aquifers have different isotope signatures. The groundwater in the aquifer situated at about 300 m depth is enriched in stable isotope content compared to that of groundwater occurring at the intermediate depth of about 150–200 m below ground level. In the intermediate aquifer, the groundwater is isotopically most depleted. Most of the samples are brackish. Shallow aquifer shows samples of variable isotope composition with measurable tritium.

Figure 4 shows δ^2H versus δ^{18}O plot of samples from the study area. It could be observed that most of the groundwater samples are depleted in δ^2H and δ^{18}O compared to the 1983 rain events in this area. The samples fall into three distinct categories.

Shallow groundwaters along the river course are isotopically enriched and fall in group C in Figure 4. These samples have higher tritium concentration ranging from 5 TU to 20 TU. These samples fall on a lower slope exhibiting a typical evaporation effect. Shallow groundwater away from the river course and located in the western and southwestern portions of the study area have comparatively depleted stable isotope composition. They fall in group B. Tritium content of these samples ranges from 1.4 TU to 4.8 TU. Some of the shallow wells show depleted stable isotope composition similar to the one exhibited by groundwater in the intermediate aquifer. These samples fall in group A.

In general shallow groundwaters along the river course have enriched stable isotope composition and high tritium. Shallow groundwaters located on the western and southwestern side of the river course and probably along the fault zone have comparatively depleted stable isotope composition and low tritium.

The depleted brackish groundwater (T2, T6, T7) having negligible tritium and occurring at an intermediate depth falls in group A in Figure 4. This aquifer does not appear to be replenished by any recent recharge.

The wells T1, T3 in the deep aquifer and T8 fall in group B in Figure 4. The well T8 taps intermediate aquifer as well as shallow aquifer. This sample shows tritium content of 3 TU and ^{14}C content of 71 pMC (uncorrected age ~ 2800 BP). Samples T1, T3 and T8 are fresh in quality. The stable isotope contents of shallow as well as deep wells (D1, D3 and T1, T3) are similar indicating interconnection between them. Also the deeper aquifer has piezometric surface at an elevation of the shallow water table.

The samples T4 and T5 fall in group C in Figure 4 and are located in the southwestern corner of the area. The well T4 at Jodhawas is of artesian flowing type and the sample has ^{14}C content of 12 pMC (uncorrected age ~ 17500 BP).

It is concluded from the isotope geochemical studies that the shallow aquifer receives recharge by infiltration through river channels during episodic floods caused by sporadic rain events. Some portions of this shallow aquifer also receive recharge from deeper confined aquifers due to upward leakage of groundwater through subsurface fault zones in the area. The deeper (~ 300 m) aquifer was replenished during the cool, pluvial period in early Holocene. The intermediate aquifer (150–200 m) was recharged during the cooler, humid period in the

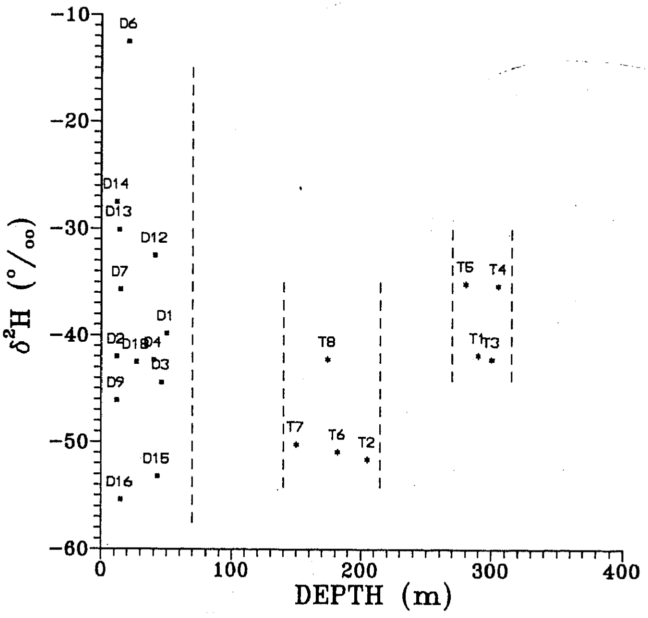

Figure 3. δ^2H vs depth (Jalore samples).

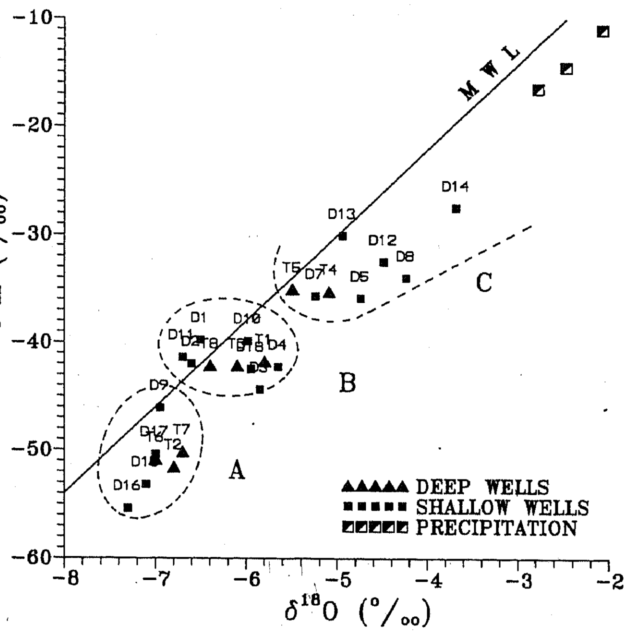

Figure 4. δ^2H vs δ^{18}O (Jalore samples).

mid Holocene. These deeper aquifers do not appear to receive any modern recharge.

Barmer district

An environmental isotope study was undertaken to study groundwater recharge processes in Bhadka–Bheemda area in Barmer district[4]. The study area is arid and receives a mean annual rainfall of 280 mm. A thin veneer of wind blown sand is present over the area. The Tertiary (Eocene) aquifer comprising loosely consolidated to consolidated arenaceous sediment with intercalations of gravel, argillaceous sediment, lignite, etc. and having generally freshwater was of particular interest. Figure 5 shows the sample locations and the geology of the study area. Lathi sandstone of Jurassic age is present on the northern side and Precambrian–Lower Palaeozoic Malani suite of igneous rocks are present on the eastern, southern and western sides. The latter are mainly rhyolites and granites. Two lenticular outcrops of the Tertiary sandstone in the central zone are found to be dry.

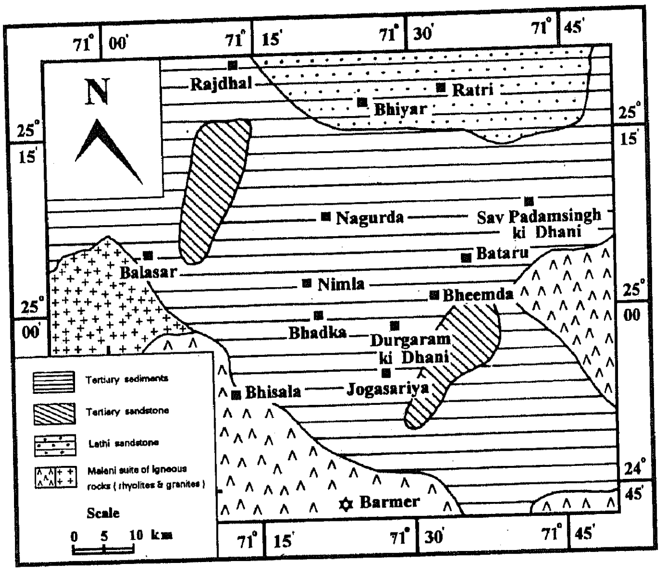

Figure 5. Barmer study area – sample locations.

In the central portion of the area, Nagurda–Nimla–Bheemda, fresh groundwater forms a basin leaving a narrow valley on the eastern and western sides. Shallow aquifers are under phreatic conditions whereas deeper ones change from semi-confined to confined conditions.

Shallow well sample from Balasar is fresh (EC = 630 μS/cm) and is of Ca–HCO_3 type. Other shallow groundwater samples are brackish and of Na–Cl type. The deep fresh groundwater is of Na–HCO_3 type and the deep brackish groundwater is of Na–Cl type. Table 2 lists the isotope and other relevant data of the Bhadka–Bheemda area.

Figure 6 shows δ^2H versus $\delta^{18}O$ plot of samples from the study area. The samples falling in the group A in the plot represent fresh deep groundwater (except the one at Bhadka which is brackish) and most of these are in the groundwater basin in the central portion of the area (except Rajdhal which is situated on the northern side in the dunal area).

The deep and shallow groundwaters from Durgaram ki Dhani and Bataru as well as other shallow samples fall in group B in Figure 6. This group has also the samples from the aquifer in the Lathi sandstone. All these samples show evaporation effect on the stable isotope content. EC also increases along the flow direction in the shallow aquifers. The samples in the group have measurable tritium indicating some component of recent recharge. Higher EC in the shallow aquifer

Table 2. Isotope and other relevant data of groundwater samples from Barmer district, Rajasthan

Sample identity	Place	Depth of well (m)	Electrical conductivity (μS/cm)	δ^2H (‰)	$\delta^{18}O$ (‰)	^3H (TU)	^{14}C (pMC)	^{14}C Model age (BP)

D4	Balasar	–	630	– 20.3	– 4.19	21.0	–	–
D5	Sav Padamsingh ki Dhani	70	3200	– 38.9	– 5.03	2.9	–	–
D6	Bhisala	40	4400	– 26.9	– 3.95	–	–	–

is probably the manifestation of the leaching of salts from soils and aeolian sand by water during return flow of irrigation as well as concentration due to evaporation. The samples, shallow as well as deep, from Durgaram ki Dhani and Bataru are a mixture of deep and shallow groundwaters. A shallow sample from Balasar is fresh and contains high (21 TU) tritium. This well probably taps groundwater from weathered igneous rocks. This sample represents water which is about three decades old.

The deeper fresh groundwater is depleted in stable isotopes and has negligible tritium. The model ^{14}C ages[5] for these samples range from 2400 to 7400 BP. This deeper aquifer appears recharged during the cooler, pluvial phase in the Holocene. No modern recharge is discernible. However, if the outcrop of Malani suite of igneous rocks is a probable recharge zone, the groundwater velocity is 6 to 10 m/a.

Indira Gandhi Nahar Pariyojana (IGNP)

The IGNP is a large irrigation and drinking water project to cater to five districts in the western Rajasthan. The Stage I of the canal is in existence for the last 15 years. The canal project is facing twin problems of waterlogging and development of secondary salinity in soils and groundwater in some areas.

The possible causes of waterlogging are: (i) Poor irrigation practices and irrigation return flow, (ii) Non-exploitation of groundwater due to poor quality, (iii) Presence of hydrological barriers at various depths which affect the process of infiltration, (iv) Seepage losses from the canal and its branches.

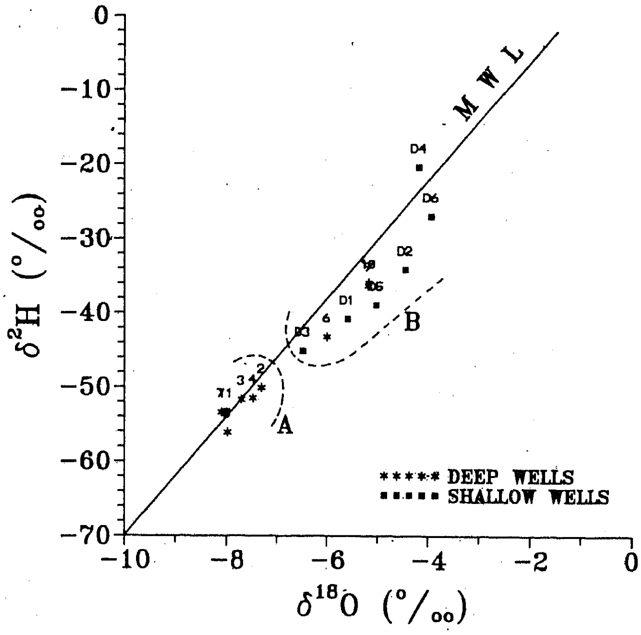

Figure 6. δ^2H vs δ^{18}O (Barmer samples).

Isotope investigation has been initiated in Suratgarh area (Figure 1) in collaboration with the Groundwater Department, Rajasthan to study the contribution to groundwater from canal seepage and irrigation return flow as well as interconnections between shallow and deep aquifers.

Figure 7 shows δ^2H versus δ^{18}O plot of samples collected in the ongoing study. The preliminary observations indicate that the canal water originating from the higher altitudes in the north is depleted in stable isotope composition compared to local precipitation and groundwater. These samples fall in group A. Groundwater samples influenced by seepages from the canal fall in group B. These samples fall on a regression line with equation, $\delta^2H = 8.2\delta^{18}O + 17.3$ ($r = 0.975$; $n = 12$). Piezometer samples affected by irrigation return flow, waterlogging and saline groundwaters fall in the group C showing evaporation effect.

Tritium level of canal water (~ 12 TU) is slightly higher than that of the precipitation (~ 9 TU). Native saline groundwaters show negligible tritium.

The canal seepage to groundwater consists of two end points; canal water and pure groundwater and the admixture. If the stable isotope compositions of the end points and those of the admixtures are known, it is possible to calculate the percentage contribution of canal water to the admixture. It is estimated that the contribution is about from 3 to 5% for a period of 15 years or so.

Lost courses of Saraswati River

The legendary 'Saraswati' river has been described as a mighty Himalayan river in the ancient Indian literature,

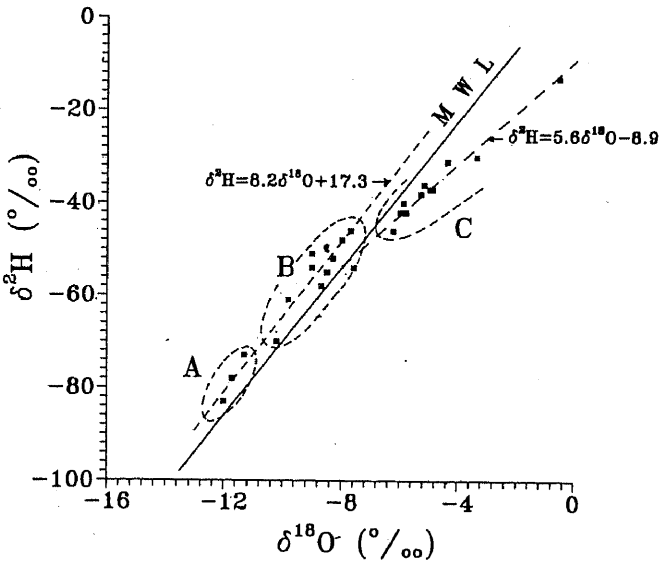

Figure 7. δ^2H vs δ^{18}O (IGNP samples).

e.g. *Rigveda*[6]. Thereafter, there have been many references to the Saraswati river and its disappearance. Early literature indicates the existence of the river before 3000 BP. Most of this literature was, however, aimed at studying the relics of the once great Indus Valley Culture in the region. Many attempts have been made to explore the former courses of the Saraswati river in the last and this century. Allchin *et al.*[7] have summarized these findings in the following way:

> 'Evidence from many sources, including that of archaeological remains associated with older river courses, indicates that a major river, stemming mainly from the same sources as the present Sutlej, flowed through Northern Rajasthan, Bahawalpur and Sind – to the southeast of the present course of the Sutlej and the Indus – in the third to second millennium BC. This river known as Saraswati in its upper course, at different times either joined the lower course of the Indus in Sind, or found its way independently into the Arabian sea via Rann of Kutch' (p. 198).

The river is supposed to have changed its course several times in the westward direction. Recently, interpretation of LANDSAT imagery of the western part of Jaisalmer district revealed buried courses of the river running from NE to SW[8,9]. This course is found to have links with the dry bed of Ghaggar river in the northeast (Ganganagar district) while in the southwest it met with or even cut across the surviving courses of the Hakra and Nara rivers in Pakistan.

In northwestern part of Jaisalmer district, in spite of very low rainfall (less than 150 mm) and extreme conditions of the desert, groundwater is available at depth of about 50–60 m along the course of the defunct river and a few dug wells do not dry up throughout the year. It is found that the area through which the river bed is traced supports vegetation even during summer. It is thought that these courses of river in the area still maintain their head water connection and could form potential groundwater sanctuaries for exploitation.

To confirm the scenario, an environmental isotope study was undertaken in collaboration with the Groundwater Department, Rajasthan in the Jaisalmer district. A set of samples collected in 1995 was analysed for isotopes δ^2H, δ^{18}O, δ^{13}C ^{3}H and ^{14}C. The preliminary observations are mentioned below.

The groundwater in the area is enriched in stable isotope content (δ^{18}O: -6 to -2‰) compared to that of Himalayan rivers (δ^{18}O: -11 to -10‰). The groundwater samples exhibit negligible tritium content indicating absence of modern recharge. Radiocarbon data suggest the groundwater is a few thousand years old. The ^{14}C levels decrease along the suspected river course downstream (58.8 pMC to 54.9 pMC) indicating hydraulic continuity of the Saraswati buried channel from Kuria Beri to Ghantiyalji. A groundwater velocity of about 20 m/a is estimated from ^{14}C data. Further work is in progress.

Concluding discussion

Deserts occupy waste regions mainly in the latitude belts between 15° and 30°. The Sahara desert in the Northern Africa, the largest in the world has a surface area of about 9 million km^2. Other large deserts are those of Arabian Peninsula and Iran (which might be considered a continuation of the Sahara), the Turkesthan desert, the Thar desert in India, the Gobi desert in Mongolia, the Great American desert and in southern hemisphere the Kalahari desert in South Africa, the Great Australian desert and Atacama desert in Northern Chile. The last, though relatively small in size, is the driest – no precipitation has been recorded over most of it for more than one century.

Western Rajasthan, which forms part of the Thar desert, has all the attributes of an arid zone – aeolian topography concealing geological features and formations, scarce and erratic rainfall and large evapotranspiration. Evidence from archaeological sites, radiocarbon and thermoluminescence dating of quartz sediment and pot shreds show that the dunes were accumulating from at least 20000 BP and were stable by the middle to late Holocene. The continuation of dune construction into the Holocene distinguishes the Thar from other mid-latitude dunefields[10].

The stabilization of dunes in Africa and Australia, and probably Arabia, broadly coincides with the global warming that post-dated the Last Glacial Maximum (LGM)[11,12]. The monsoon circulation ceased to exist during LGM[13]. It is most likely that the monsoon circulation re-established during the global warming that began around 14000 BP (ref. 11). This warming peaked in the period 8000–6000 BP, along with a general water surplus which, in many places, has been interpreted as the result of increased rainfall[14].

The history of lacustrine sedimentation in the Thar shows that hypersaline conditions prevailed at about the LGM and violent fluctuations of water level occurred between this maximum of aridity and the onset of freshwater conditions about 6000 BP. Freshwater, high lake level conditions prevailed until about 4000 BP when sediments rather like those of today began to be deposited[10].

Singh *et al.*[15] carried out a pollen analytical study of lakes, providing a Holocene record of vegetation changes in the northern Thar. They were able to propose a series of climatic changes:

Phase 6	1100–0 BP	Conditions same as today (ephemeral playas with very thin halite crust)
Phase 5	3000–1100 BP	Drying of lakes and lack of pollen
Phase 4	5000–3000 BP	Wettest period – lacustrine conditions and swamp vegetation, increased rainfall
Phases 2 and 3	10000–6000 BP	Wet period – lacustrine conditions with rainfall greater than at present
Phase 1	Beyond 10000 BP	Active dune development

Isotope hydrological studies carried out in western Rajasthan essentially echo the climatic changes mentioned above, especially phases 2, 3 and 4. The replenishment of groundwater resources took place in the early to mid Holocene in the Thar desert. The depleted stable isotopic composition and low radiocarbon content of groundwaters in deeper aquifers suggest cool, pluvial phase(s) in the Holocene responsible for the replenishment. Moreover, comparison of isotopic composition (δ^2H and $\delta^{18}O$) and radiocarbon content of groundwaters from Jalore and Barmer areas indicates that the climatic conditions in the Thar desert changed from cool, pluvial in early Holocene to cooler, pluvial in the mid-Holocene. However, more comprehensive isotope hydrological data will shed more light on the climatic aspects of the Thar desert.

It is true that groundwater is relatively abundant under most of the deserts, but is seldom easily accessible. Also practical implementation of rational exploitation of groundwater and agricultural development of desert is rather problematic. In most of the deserts, including the Thar desert, the need for an accurate assessment of whether a small quantity of rainfall recharge is occurring appears rather academic when the withdrawal from an aquifer clearly surpasses the present day maximum possibilities of infiltration through catchment area. The heavy withdrawal of groundwater will not only pose the problems of accessibility but also of the stability of the ground due to pressure decrease as well. The conjunctive use of precious groundwater resources with improved irrigation practices will help arrest the secondary soil and groundwater salinization.

Isotope techniques are an important tool in arid-zone hydrology. When applied effectively with multi-disciplinary approach, one can evaluate groundwater recharge, investigate recharge processes, understand the dynamics of groundwater, study mechanism of salinization and related problems among others. The information will also help in planning the development of groundwater resources through artificial recharge of aquifers. From the foregoing, it is clear that isotope techniques should form an integral part of any hydrogeological investigation undertaken for the development of groundwater resources, particularly in the arid zones.

Solar energy in western Rajasthan

S. P. Sukhatme and J. K. Nayak

Department of Mechanical Engineering, Indian Institute of Technology, Powai, Mumbai 400 076, India

This article reviews the state-of-the-art for generating electricity from solar energy, through the photovoltaic and thermal routes. On the whole, India has made significant efforts for the successful utilization of solar energy. A large number of kilowatt scale PV power packs and systems for a variety of applications have been installed. Successful attempts have also been made to integrate a few PV systems with the grid. As regards the thermal route, the experience of generating electricity has been limited. However, ambitious plans are afoot for setting up a few large power plants in western Rajasthan where the conditions are most appropriate for the utilization of solar energy.

ENERGY from the sun sustains life on our earth. It is also the source of almost all forms of energy used by man. Fossil fuels such as coal, oil and natural gas represent solar energy that was received on earth millions of years ago, while renewable sources of energy like wind, hydroelectric power, biomass and ocean energy are indirect forms of solar energy.

Solar energy, as received directly, can be used in a number of ways and for many applications. The two routes for utilization are the thermal route using the heat for heating, cooling, drying, water purification, power generation, etc. and the photovoltaic route which converts the light into electricity which can then be used for a variety of purposes such as lighting, pumping, communication and refrigeration. In this article, we focus on various technologies and systems using solar energy directly for generating electricity.

India receives solar energy equivalent to over 5000 trillion kWh/year which is many times more than the total energy consumption of the country. The daily average incident solar energy varies from 4 to 7 kWh/m^2 depending upon the location and there are 250–300 sunny days in most parts of the country. The potential for using solar energy to meet the growing energy needs of the country was recognized in the mid seventies. Research and development efforts in both solar thermal and photovoltaic routes were initiated. Several applications were developed and demonstrated during the eighties. These efforts received an impetus with the establishment of the Ministry of Non-Conventional Energy Sources (MNES) in 1992. The Ministry's programmes include R&D, demonstration, commercialization and utilization activities in respect of a wide variety of renewable energy technologies. The programmes are implemented through a network of state level agencies, industrial, research and academic organizations and non-governmental bodies. As a result of these efforts, India today has one of the world's largest programmes in solar energy. Solar energy is beginning to be used for a large number of applications. Nevertheless, the achievements so far add up to only a tiny fraction of what is possible. The efforts initiated during the last three years by MNES to restructure the programmes and give them a market orientation could lead to a significant acceleration in the utilization of solar energy in the country.

Availability of solar radiation over western Rajasthan

Rajasthan is the second largest state in size in the country, covering about 10.4% of the land area. The state has limited traditional sources of energy. It has only two perennial rivers, the Chambal and the Mahi, whose hydroelectric potential has been almost fully exploited. There are no coal mines or oil fields. However, there are some gas and lignite reserves.

In order to discuss the potential for using solar energy in western Rajasthan, it is desirable to examine the climatic conditions of that region. The variables of importance from the point of view of generating solar electricity, are solar radiation, sunshine hours, clearness index and ambient temperature.

Western Rajasthan experiences a hot and dry climate with a severe summer, relatively clear skies, a short monsoon period and a cold winter. Table 1 presents annual and monthly averages of daily values of global solar radiation, sunshine hours and clearness index for four towns of the region. In order to get a comprehensive picture of the spatial distribution of these quantities over the whole area, a map showing the distribution of the annual mean daily global solar radiation and the clearness index is presented in Figure 1. It is seen that the solar insolation level is high. In fact, the values over western Rajasthan are the highest for the whole country. Further, the sunshine hours and values of clearness index for the region are consistently high, except for a short monsoon period. This implies an excellent availability of beam radiation. Consequently solar devices which need concentration of radiation would perform much better in this region. Besides these factors, the ambient temperatures are high throughout the year touching more

than 45°C during the summer. Thus the region is the best in the country from the point of view of utilizing solar energy.

Photovoltaic technology

Photovoltaic (PV) technology enables the direct conversion of sunlight into electricity. A photovoltaic module is the basic building block of a PV system. The power from the PV module can be used to run pumps, lights, refrigerators, TV sets, etc. The PV modules, batteries, charge controller, inverter (if any), mounting structure, cables, switches and the appliances being powered together constitute a complete PV system.

PV power systems have several advantages. They are modular in nature and have no moving parts, produce no noise or pollution and require very little maintenance. They can be installed almost anywhere, making them an ideal power source for use in remote and isolated areas which are not served by conventional electricity.

With 75,000 villages still to be electrified, there is a vast scope and potential for use of PV technology in India. Recognizing this fact, the government has been implementing a comprehensive programme covering R&D, demonstration, commercialization and utilization aspects for over 15 years. The technology for the fabrication of solar cells using single crystal silicon wafers has been developed and commercialized in the country based on indigenous efforts. This was followed by further demonstration of the applications in different sectors and the development of newer technologies such as amorphous silicon and other thin film technologies.

India has acquired a leading status among the countries of the world in the development and use of PV technology. The Indian market and programme are the largest among developing countries and India has emerged as the second largest manufacturer of PV modules based on crystalline silicon technology. Industrial production touched a level of 7 MW during 1995–96. There are over 75 companies now engaged in the production of solar cells, modules and systems. There are seven solar cell manufacturers and ten PV module manufacturers in production.

Some applications for which PV systems have been developed are:

1. Pumping water for irrigation and drinking.
2. Electrification for villages for providing street lighting and home lighting and for providing community services.

3. Telecommunication for the posts and telegraph and railway communication network, and for other specialized purposes.

A diagram of a typical system for pumping water from a bore well is shown in Figure 2. A solar cell array supplies power through a dc–ac inverter to an electric motor coupled to a submersible pump. The pump is installed below the water level of the bore well. Its discharge is connected through a delivery pipe to a storage tank at ground level. Water can be withdrawn from the storage tank for use when required. Usually systems for pumping water do not have storage batteries and work only during the day when adequate solar radiation is available. However, other PV systems which have to supply power during the evening or night have storage batteries to store the electrical energy generated during the day, the capacity of the battery being determined by the nature of the application.

Rajasthan is one of the leading states in the country in utilizing solar photovoltaic technology for decentralized and stand-alone systems. With assistance from the Central Government, the Rajasthan Energy Development Agency (REDA) has been implementing a programme for providing PV lighting systems in its rural and remote villages. Under this scheme the State has deployed 5545 street lighting systems, 4700 solar lanterns and 115 community TV systems.

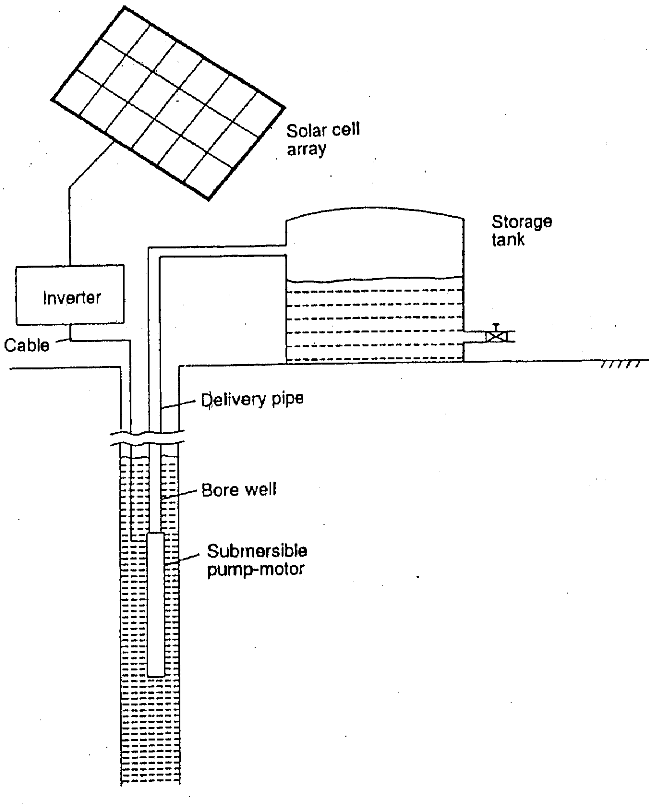

Figure 2. A photovoltaic water-pumping system.

Nineteen village level PV power packs of 113 kWp aggregate capacity have also been installed till June 1996 (ref. 1). The PV power packs comprise individual home lighting systems for each household, a few street lighting systems, a community TV system for education and entertainment and a community drinking water pumping system. A typical power pack has a capacity of about 10 kW peak and comprises 80 home lighting systems, 20 street lighting systems, two community TV systems and a community water pumping system. Such systems have been functioning satisfactorily for the last 5 years.

Most of these power packs have been installed in villages in Jaisalmer and Udaipur districts. Over the years, REDA has evolved a method for maintenance and servicing of these power packs with the active co-operation of the beneficiaries and system suppliers.

The Rajasthan Government has also proposed that 552 villages in the districts of Udaipur, Jaisalmer and Ganganagar be electrified with PV power packs. The above villages are not likely to be electrified by conventional grid power during the next 5–10 years. The aggregate PV capacity of these systems is about 1.44 MWp and the total cost is likely to be about Rs 66 crores.

Recently efforts are also being directed towards establishing and demonstrating the potential of solar photovoltaics to generate larger amounts of power which would supplement and augment grid power. MNES has completed two pilot village electrification projects of 100 kW each, with 25 kW grid connected components. The projects have provided initial insights for the design of high voltage systems, power conditioning unit, grid integration, etc. The Ministry is now in a position to demonstrate various grid-connected possibilities based on new design concepts and more such projects are planned. It is expected that higher conversion efficiencies and optimally engineered systems will bring about rapid market expansion, which will eventually lead to a decline of costs of PV systems. This stage is likely to be reached by the turn of the century when solar photovoltaics could approach competitiveness for grid-connected applications.

Keeping in mind the above developments, the Government of Rajasthan has issued Letters of Intent for the establishment of two large-sized PV solar power plants which would be connected to the grid. Both these plants have a capacity of 50 MW. One is based on PV thin film technology and the other on PV modules using concentrators. The plants are to be established on a build, own, operate and maintain (BOOM) basis and the commitment of the State Government is to buy the power generated from these plants at the following rates:

Rs 2.25 per unit for the first three years,
Rs 2.70 per unit for the fourth year,
Rs 3.82 per unit for the next seven years and

Rs 2.25 per unit for the remaining period up to 25 years.

Solar thermal power generation systems*

Solar thermal power systems can be classified as working on low, medium and high temperature cycles. Low-temperature cycles work at maximum temperatures of about 100°C, medium-temperature cycles work at maximum temperatures up to 400°C, while high-temperature cycles work at temperatures above 400°C (ref. 2).

Low-temperature systems use flat-plate collectors or solar ponds for collecting solar energy. Recently, systems working on the solar chimney concept have been suggested. Medium-temperature systems use the line focussing parabolic collector technology. High-temperature systems use either paraboloidal dish collectors or central receivers located at the top of towers.

Low-temperature systems

A diagram of a typical low-temperature system using flat-plate collectors and working on a Rankine cycle is shown in Figure 3. The energy of the sun is collected by water flowing through the array of flat-plate collectors. The hot water at temperatures close to 100°C is stored in a well-insulated thermal storage tank. From here, it flows through a vapour generator through which the working fluid of the Rankine cycle is also passed. The working fluid has a low boiling point. Consequently, vapour at about 90°C and a pressure of a few atmospheres leaves the vapour generator. This vapour then executes a regular Rankine cycle by flowing through a prime mover, a condenser and a liquid pump. The working fluids normally used are organic fluids like methyl chloride and toluene, and refrigerants like R-11, R-113 and R-114.

It has to be noted that the overall efficiency of this system is rather low, because the temperature difference between the vapour leaving the generator and the condensed liquid leaving condenser is small. For the cycle shown in Figure 3, the Rankine cycle efficiency is about 7–8%. The efficiency of the collector system is of the order of 25%. Hence an overall efficiency of only about 2% is obtained. Because of the low overall efficiency, large collector areas are required and such plants have been found to be very costly. Typically the installed cost is about Rs 300,000 per kW for 6 to 8 h of daily operation, the main component of cost being the collectors.

In order to reduce the cost, solar ponds have been used instead of flat-plate collectors. The first two solar pond power plants having capacities of 6 kWe and 150 kWe were constructed in Israel about 15 years ago. These were followed in 1984 by the Bet Ha-Arava power plant, the largest in the world with a capacity of 5 MW. The working of these plants has established the technical viability of solar pond power plants. However, they also do not appear to be economically attractive.

Recently the concept of a solar chimney power plant has been suggested. In such a plant, a tall central chimney is surrounded at its base by a circular greenhouse consisting of a transparent cover supported a few metres above the ground by a metal frame (Figure 4). Sunlight passing through the transparent cover causes the air

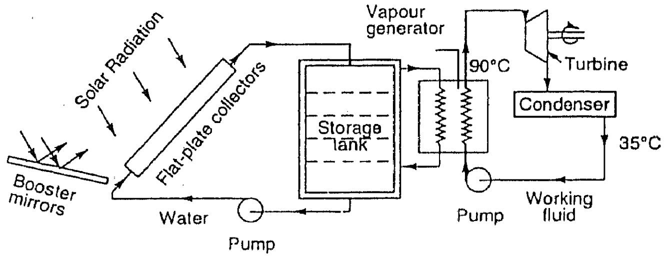

Figure 3. Low temperature power generation cycle using flat-plate collectors.

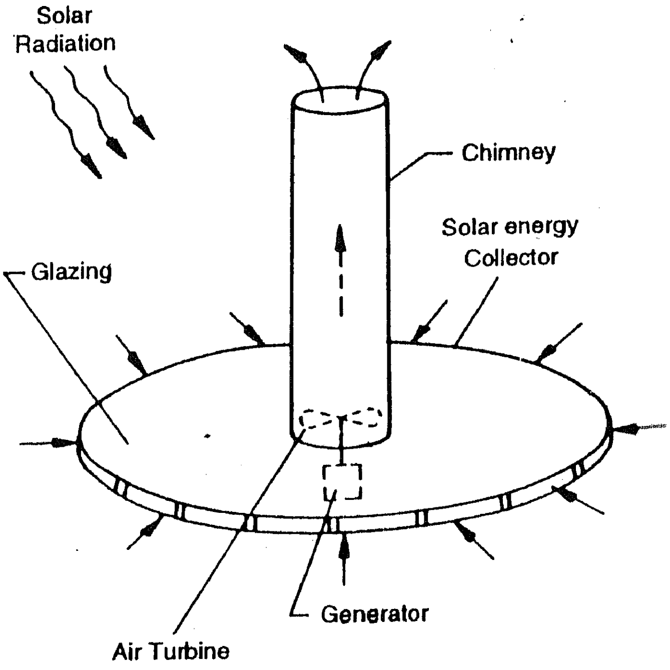

Figure 4. Solar chimney power plant.

---

*From a historical view point, it is of interest to note that the first experiments on the generation of solar thermal power in India were conducted by an Englishman, William Adams, more than one hundred years ago. Adams stayed in Mumbai and performed his experiments in the compound of his bungalow. He has described his work in a book entitled *Solar Heat – A Substitute for Fuel in Tropical Countries for Heating Steam Boilers and Other Purposes* (Education Society's Press, Byculla, Mumbai, 1878).

trapped in the greenhouse to heat up. A convection system is set up in which this air is drawn up through the central chimney turning a turbine located near the base of the chimney. The hot air is continuously replenished by fresh air drawn in at the periphery of the greenhouse.

The only solar chimney power plant built so far is a 50 kW pilot plant in Spain. It has a 200 m high chimney with a diameter of 10.3 m. The solar collector area extends to a radius of 126 m from the chimney with the glazing being 2 m above the ground. The turbine, housed at the base of the chimney, has four 5 m long blades and rotates at 1500 rpm to produce an output of 50 kW.

Although the energy conversion efficiency of such plants is low (less than 1%), it is claimed that there will be considerable reduction in cost with scale-up and that a large size 1000 MW plant may cost only about $ 1000 per kW.

Medium-temperature systems

Among solar thermal-electric power plants, those operating on medium-temperature cycles and using the line focussing parabolic collector technology at a temperature of about 400°C have proved to be the most cost effective and successful so far. A schematic diagram of a typical plant is shown in Figure 5. The first commercial plant of this type having a capacity of 14 MW was set up in 1984. Since then six plants of 30 MW capacity each, followed by two plants of 80 MW each have been installed and commissioned. All these plants have been set up in California, which has a total installed capacity of 354 MW. The collector array for the 80 MW plant has an area of 464,340 m^2. The cylindrical parabolic collectors used have their axes oriented north-south. The absorber tube used is made of steel and has a specially developed selective surface. It is surrounded by a glass cover with a vacuum. The collectors heat a synthetic oil to a temperature of 400°C with a collector efficiency of about 0.7 for beam radiation. The synthetic oil is used for generating superheated high pressure steam which executes a Rankine Cycle with an efficiency of 38%. The plant generally produces electricity for about 8 h a day and is coupled with natural gas for continuous operation. The installed cost of this type of plant has reduced over the years because of the increasing installed capacity. The latest 80 MW plant is reported to have cost $ 2900 per kW. The generating cost is about 8 cents per kWh.

The Indian experience with the line focussing parabolic collector technology has been restricted so far to a small

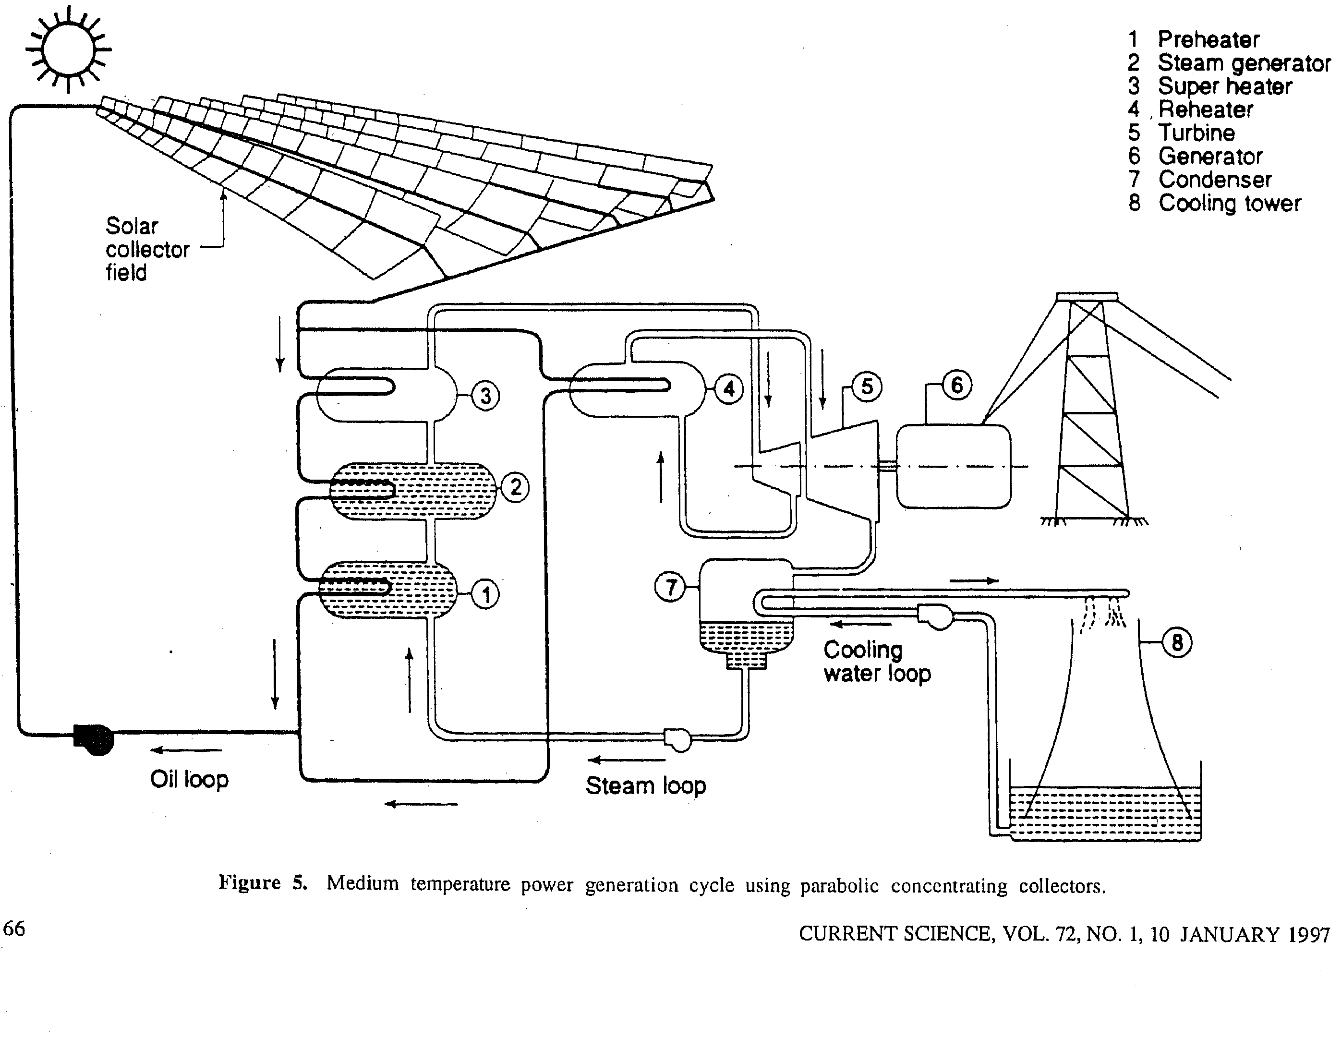

Figure 5. Medium temperature power generation cycle using parabolic concentrating collectors.

50 kW capacity experimental plant installed at the Solar Energy Centre near Delhi.

High-temperature systems

Two concepts have been tried with high-temperature systems. These are the paraboloidal dish concept and the central receiver concept.

In the paraboloidal dish concept, the concentrator tracks the sun by rotating about two axes and the sun's rays are brought to a point focus (Figure 6). A fluid flowing through a receiver at the focus is heated and this heat is used to drive a prime mover. Typically Stirling engines have been favoured as the prime movers and systems having efficiencies up to 30% and generating power in the range of 8 to 50 kWe have been developed.

The Indian experience with this type of system has been restricted to a small 20 kW power station near Hyderabad set up in the eighties. Four paraboloidal dish collector modules were used to generate steam which ran a steam engine.

Because of limitations on the size of concentrator, paraboloidal dish systems would generally be expected to generate power in kilowatts rather than megawatts. Thus they can only be expected to meet the local power needs of communities, particularly in rural areas.

In central receiver power plants, solar radiation reflected from arrays of large mirrors (called heliostats) is concentrated on a receiver situated at the top of a supporting tower. A fluid flowing through the receiver absorbs the concentrated radiation and transports it to the ground where it is used to operate a Rankine power cycle. A schematic diagram showing the main components of a central receiver power plant in which water is converted into steam in the receiver itself is shown in Figure 7. Alternatively the receiver is used to heat a liquid metal or a molten salt and this fluid is passed through a heat exchanger in which steam for the power cycle is generated. Seven central receiver power plants have been built in the eighties. All these plants were pilot plants and had outputs ranging from 0.5 to 10 MWe. A few details are given in Table 2. These include the number and the size of the heliostats, the receiver type, the receiver fluid and the height of the central supporting tower.

Although all the central receiver plants have been operated successfully, the available data indicate that the construction cost was very high. For example, the largest plant, Solar One, at Barstow, California cost approximately $ 14,000 per kW. However, costs are likely to reduce with more operational experience, improved design and scale-up.

Recently, Solar One has been converted from a water–steam system to a more advanced system using a molten salt. The molten salt at 290°C is pumped from a cold storage tank through the receiver where it is heated to 560°C, and then on to a hot storage tank. When electricity is to be generated, the hot salt is pumped to a steam-generating system that produces superheated steam for the turbine/generator. After giving up its heat, the salt

is returned to the cold storage tank. The converted plant, called Solar Two, began operation in June 1996 (ref. 3). It is expected that the use of molten salt will result in a higher efficiency and a better operating performance.

The Government of Rajasthan has also issued a Letter of Intent for a large 200 MW solar thermal power plant. The plant would be established on a BOOM basis and the State Government has made a commitment to purchase power at the same rates as for the two proposed 50 MW PV-based plants. The indications given are that the plant would be based on the solar chimney concept and located in Jaisalmer district. The plans are to construct the plant in stages with the chimney height as well as the collector area on the ground being increased in steps. The chimney would initially be 300 m in height, then raised to 600 m and finally to a height of 1000 m. The total collector area would finally be about 100 million m^2.

The other large power plant planned for Rajasthan is proposed to be located in Jodhpur district. It will be a 140 MW integrated solar combined cycle power plant with about 35 MW being generated from solar energy using the line focussing parabolic collector technology. The balance power of about 105 MW will be generated by conventional means using fossil fuels[1]. It is expected that this mix would be the most techno-economically feasible and viable option. A detailed feasibility report has been prepared and a laboratory established for collection of meteorological data at the selected site. Indications are that the total project cost may be of the order of $ 280 million. The mode of implementation, pattern of funding, and the role of various organizations are being finalized.

Concluding remarks

We have reviewed the state-of-the-art for generating solar electricity by the photovoltaic as well as the thermal route. As far as PV-based systems are concerned, the country has done well in developing indigenous technology and in setting up a large number of kilowatt scale power packs and systems for a variety of applications. Successful attempts have also been made to integrate these systems with the grid on the kilowatt scale. In so far as the thermal route is concerned, the domestic experience has been limited. However, an ambitious 140 MW integrated plant is planned for western Rajasthan. This should give the right impetus to the solar power generation programme.

Correction in the reported amino acid sequence for human seminal plasma prostatic inhibin

Vinit K. Rastogi, K. V. R. Chary and Girjesh Govil

Chemical Physics Group, Tata Institute of Fundamental Research, Homi Bhabha Road, Mumbai 400 005, India

NMR studies on human seminal plasma prostatic inhibin (HSPI) reveal that the amino acid at position 93 is Ile and not Gly as was reported earlier. This suggests that HSPI and prostatic secretory protein are one and the same protein.

HUMAN seminal plasma contains a variety of proteins secreted by seminal vesicles and the prostate. Human seminal plasma prostatic inhibin (HSPI), prostatic secretory protein (PSP-94), immunoglobulin binding factor (IgBF) and β-microseminoprotein (β-MSP) are among the human seminal proteins which have been isolated, purified and characterized during the last decade. All these proteins have close (~ 99%) sequence homology. HSPI, first isolated by Sheth and his coworkers[1], has biological activity ranging from preventing pregnancy to curing prostate cancer. Inhibin prevents pregnancy in mammals by modulating the level of circulating follicle stimulating hormones (FSH)[2]. It suppresses prolactin, a hormone that promotes lactation[3]. Therefore, neutralizing inhibin through active immunization leads to increase in milk production. Seidah *et al.* have reported the primary sequence of HSPI[4]. This was followed by the discovery of PSP-94 (ref. 5) which showed complete sequence homology with that of HSPI except for one amino acid residue at position 93. HSPI is reported to contain Gly at this site whereas PSP-94 has Ile (Figure 1).

Around the same time, Kazuko *et al.* isolated β-MSP[6] which was reported to be a 93 residue protein showing differences in sequence homology at positions 39 and 40 from PSP-94. While β-MSP contains Pro and Thr at these positions, PSP-94 and HSPI have Thr and Cys, respectively (Figure 1). Another group, Zhi *et al.*[7] who purified and characterized IgBF, reported the primary sequence of only thirty N-terminus and two C-terminal amino acids of IgBF, which show complete sequence homology with the corresponding stretches of PSP-94. On the basis of such sequence homologies, Zhi *et al.*[7] suggested that HSPI, PSP-94, β-MSP and IgBF may be the same protein.

No information is available about the three-dimensional (3D) structure of these proteins. We have undertaken studies on the 3D structure of HSPI using multidimensional NMR spectroscopy. Our investigations unequivocally establish that the amino acid at position 93 is Ile and not Gly.

Semen samples of healthy men obtained at infertility clinics were pooled. The material was centrifuged at 3000 rpm for 10 min at 4°C. The pellet containing sperms was discarded. The supernatant was mixed with four volumes of freshly distilled chilled ethanol, allowed to settle overnight at 4°C, and then centrifuged at 3000 rpm for 30 min to separate precipitated proteins. The precipitate was washed with chilled acetone followed by chilled ether, and finally air dried to yield the crude extract which served as the starting material for purification of the protein.

The crude extract powder was dissolved in 100 ml 0.05 M sodium deuteroacetate buffer, pH 4.0. Deuterated buffer was used to avoid the interference of resonances arising from the residual acetate in the NMR spectrum. Fractionation of the crude extract was effected on a Sephadex G-100 column (110 cm × 5 cm) (Pharmacia) using 0.05 M sodium acetate, pH 4.0 for equilibration and elution. Fractions monitored at 280 nm were collected at a flow rate of 1 ml/min and pooled on the basis of the elution profile. The active fraction from sephadex G-100 chromatography was concentrated by lyophilization and equilibrated by dialysis with tris-HCl buffer (0.05 M), pH 8.0. About 1 g of immunoactive material was loaded on a DEAE cellulose column (30 cm × 2.5 cm). The column was first washed with tris buffer to remove the unadsorbed proteins till it showed negligible OD at 280 nm using a flow rate of 0.5 ml/min. The adsorbed proteins were then eluted with Tris buffer containing 0.0–0.2 M sodium chloride continuous gradient. The immunoactive fractions were further purified by HPLC on a gel permeation preparative column (Ultropack TSK G-2000 SWG; 21.5 mm × 600 mm) with an exclusion limit of 200,000 daltons. The proteins were eluted with 0.05 M acetate buffer, pH 4.0 at a flow rate of 3 ml/min. The HPLC purified material was dialysed and lyophilized. The activity of HSPI was checked by radioimmunoassay[8].

Two-dimensional (2D) NMR experiments were carried out on a Varian Unity plus spectrometer with a ^{1}H frequency of 600 MHz. The 2D experiments in ^2H_2O included two-quantum-filtered correlation spectroscopy (2QF-COSY)[9], three-quantum-filtered correlation spectroscopy (3QF-COSY)[10], clean total correlation spectroscopy (clean-TOCSY)[11] with a mixing time of 80 ms, and nuclear Overhauser enhancement spectroscopy (NOESY)[12] with a mixing time of 150 ms. Spectra in 90% H_2O + 10% ^2H_2O included WATERGATE NOESY[13] with a mixing time of 200 ms and clean-TOCSY with a mixing time of 100 ms.

In the previously reported HSPI sequence of 94 residues all amino acid residues except alanine are present. The number of various amino acids is as follows: Gly: 5, Val: 6, Leu: 2, Ile: 6, Asp: 5, Asn: 5, Cys: 10, Ser: 7, Thr: 8, Glu: 8, Gln: 2, Met: 1, Arg: 2, Lys: 11, Pro: 5, Phe: 2, Tyr: 4, His: 1, Trp: 2. HSPI is particularly rich in lysines and cysteines. Though the occurrence of 11 lysine residues in a protein of 94 amino acids is not uncommon, the number of cysteine residues[10] is much higher than the statistical average for proteins of similar size. The spin systems of most of these residues have been identified using 2D NMR spectra recorded in ^2H_2O solution, which has been followed by sequence-specific resonance assignments using standard strategies[14]. The procedures involve identifying individual amino-acid spin systems using J-correlated spectroscopy followed by detection of sequential cross peaks arising from short distances (d_{NN}, $d_{\alpha N}$, $d_{\beta N}$ etc.) in the NOESY spectrum[14]. A relatively large percentage of unique dipeptide segments in HSPI, makes sequence-specific ^{1}H-NMR assignments much simpler. Search for a possible ambiguity in the primary sequence at position 93 started from the sequence-specific assignment of the two tryptophans (Trp32 and Trp92). In the NOESY spectrum Trp N(ε^1)H proton is easily identifiable because of its inherent chemical shift which is most down-field shifted (~ 10.3 ppm) in the ^{1}H spectrum (Figure 2). Two distinct nOes are observed for Trp N(ε^1)H arising from C(δ^1)H and C(ζ^2)H of the indole rings. The distinction between the two protons has been achieved from the observation of N(ε^1)H–C(δ^1)H cross peak in the TOCSY spectrum in H_2O (not shown here). N(ε^1)H and C(ζ^2)H are not J-coupled hence do not show mutual interaction in the TOCSY spectrum. However, since the inter-proton distance is 2.84 Å one observes strong nOe between these protons which helps in the identification of C(ζ^2)H (Figure 2). From the knowledge of C(ζ^2)H position,

	1 5		32		42		92		94

Figure 1. Amino acid sequence of HSPI and related proteins isolated from human seminal plasma.

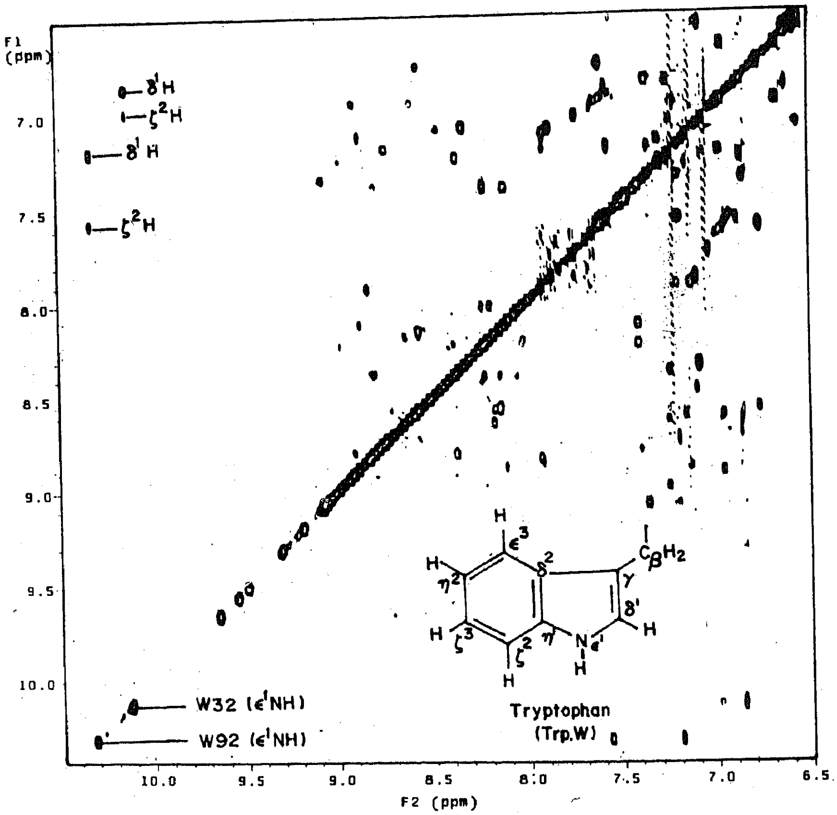

Figure 2. Selected region of the water-gated NOESY spectrum of HSPI recorded in 90% H_2O + 10% ^2H_2O at 20°C and pH 3.0. This shows the nOe connectivities from the side chain N(ε^1)H of two tryptophans to their respective C(δ^1)H and C(ζ^2)H protons. Experimental parameters: $t_1$max = 37.5 ms; $t_2$max = 256 ms; recycle delay = 1 s, 160 scans/t_1 increment. TD = 600 and 4096 along t_1 and t_2 dimensions, respectively. The data were multiplied with sine bell window functions shifted by $\pi/4$ and $\pi/8$ along t_1 and t_2 axes, respectively and zero filled to 1024 data points along t_1 dimension prior to 2D-FT. Digital resolution along ω_1 and ω_2 corresponds to 7.8 and 3.9 Hz/pt, respectively. The inset shows the indole ring of tryptophan with the standard nomenclature used for numbering the hydrogen atoms.

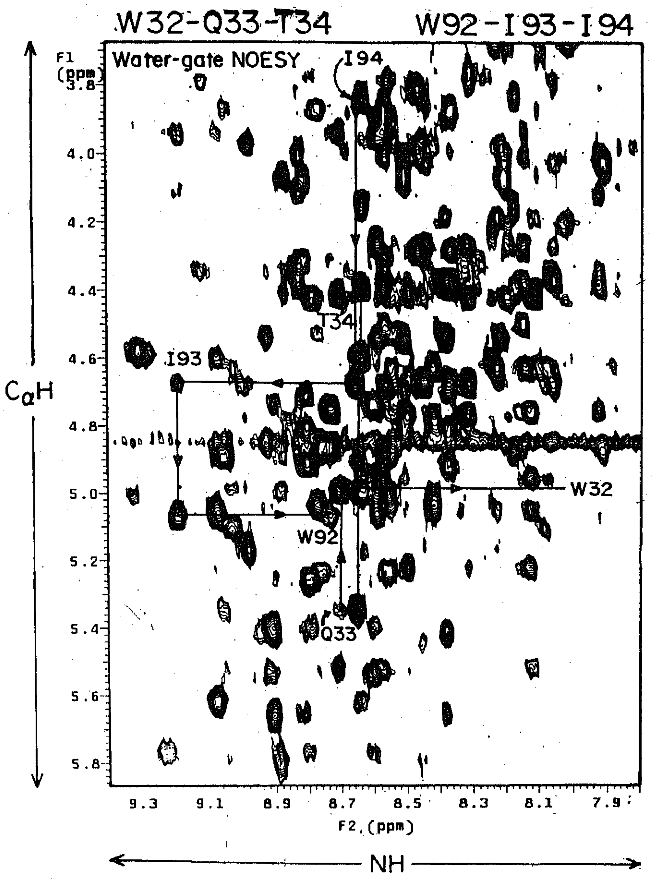

Figure 3. Finger-print region of the WATERGATE NOESY showing sequential connectivities (solid lines) for the protein segment Trp32–Gln33–Thr34 and Trp92–Ile93–Ile94.

the rest of the indole ring protons $C(\zeta^3)H$, $C(\eta^1)H$ and $C(\varepsilon^2)H$ have been assigned from the TOCSY spectrum in ^2H_2O (not shown here). We could identify both sets of indole proton resonances arising from the two Trp residues. Further, the intra-residue nOes $C(\delta^1)H$ to $C(\alpha)H$ and $C(\beta)H$ protons and $C(\alpha)H$ to NH (backbone) allowed complete identification of the remaining protons of the tryptophans. With this knowledge, nOe cross-peaks corresponding to sequential distances $d_{\alpha N}$, $d_{\beta N}$ and d_{NN} between neighbouring amino acid residues were assigned. This led to assignment of the glutamine and isoleucine spin systems (Figure 3), as sequential neighbours of Trp32 and Trp92, respectively. Sequential connectivities of Gln33 and Ile93 with Thr34 and Ile94, respectively confirm these assignments (Figure 3). The fact that segments Trp32–Gln33–Thr34 and Trp92–Ile93–Ile94 are unique in the polypeptide primary sequence, substantiates the sequence-specific resonance assignment. Thus, it could be unequivocally established that the amino acid at position 93 is Ile and not Gly as reported earlier. This is further supported by the identification of only four Gly residues in the COSY spectrum instead of five expected, if the amino acid at position 93 was Gly. Such a sequence correction suggests that HSPI and PSP-94 are one and the same protein.

Liv.100 pretreatment inhibits the CCl_4 induced lipid peroxidation in rat liver – An *in vitro* study

V. Suja and C. S. Shyamaladevi

Department of Biochemistry, University of Madras, Guindy Campus, Madras 600 025, India

The protective effect of Liv.52 and Liv.100 against *in vitro* peroxidation induced by carbon tetrachloride in rat liver homogenate has been studied. Lipid peroxidation was measured in terms of thio-barbituric acid reactive substances (TBARS), and reduced glutathione was also assayed. Addition of the two polyherbal formulations, Liv.52 and Liv.100, inhibited the peroxidation effect of carbon tetrachloride in a dose and time-dependent manner. The results suggest on the antioxidant potential of Liv.52 and Liv.100. Liv.100 is a new ayurvedic formulation.

LIPID peroxidation is a natural phenomenon and occurs on exposure to oxygen[1]. Active oxygen molecules such as superoxide radicals ($O_2^{\cdot -}$, ^-OOH) and hydroxyl radicals ($OH^{\cdot}$) play an important role in the inflammation process after intoxication by carbon tetrachloride, ethanol or carrageenan[2–5]. These radicals react with cell membranes, induce lipid peroxidation and have been implicated as important pathologic mediators in many clinical conditions[6–8]. This communication is based on the potential of the two ayurvedic formulations, Liv.52 and Liv.100. Liv.52 is commercially available in India and has been reported to be clinically effective in treating hepatotoxicity and a wide range of liver diseases[9–11]. Recent reports also suggested the protective effect of Liv.52 against radiation-induced chromosome damage[12,13] (lipid peroxidative changes) in mouse bone marrow. Therefore, an attempt was made to study the effect of the new ayurvedic formulation Liv.100 on lipid peroxidation in rat liver homogenate exposed to carbon tetrachloride challenge and compared with that of Liv.52. Liv.100 is also a product of Himalaya Drug Co, a polyherbal preparation composed of *Cichorium intybus*, *Solanum nigrum*, *Phyllanthus amarus*, *Piccorhiza curra* and *Embelica ribes* in the ratio 5 : 3.75 : 2.62 : 2 : 1. These herbs are individually reputed for their hepatoprotective nature[9,11,14,15].

Male albino rats of wistar strain (100 ± 125 g) maintained on a standard pellet diet supplied by M/s Hindustan Lever Ltd (Bangalore, India) and water *ad libitum* were used for the experiment.

Rats were sacrificed by cervical dislocation and liver was immediately excised. A homogenate (1 g, w/v) was prepared using phosphate buffer saline (PBS), pH 7.4, in cold. It was centrifuged at 2000 *g* for ten minutes. Supernatant was collected and finally suspended in PBS. It contained approximately 0.8–1 mg protein in 1 ml of suspension. This was used to perform the *in vitro* experiment.

To establish the role of Liv.52 and Liv.100 on carbon tetrachloride-induced lipid peroxidation[16], different concentrations of Liv.52 and Liv.100 were added to 3 ml of liver homogenate, mixed and incubated at 37°C for 20 min. This was followed by the addition of carbon tetrachloride (1 mM), mixed gently and further incubated at 37°C for 25 min to induce the production of TBA-reactive substances (TBARS). The control group contained buffer and different concentrations of Liv.52 and Liv.100. Lipid peroxidation was measured in terms of TBARS as described by Yagi *et al.*[17] with slight modification and reduced glutathione was measured by the method of Ellman[18]. Protein was determined by the method of Lowry *et al.*[19] using bovine serum albumin as standard.

The results presented in the paper are the mean ± SD of six animals. Level of significance has been evaluated by using Student's *t*-test.

The reaction mixture that contain carbon tetrachloride *per se* resulted in a significant increased ($P < 0.001$) formation of TBARS (Table 1). Addition of the two drugs proved their protective nature against carbon tetrachloride-induced lipid peroxidation. A significant ($P < 0.001$) dose-dependent effect was afforded by the drugs, and did not show any augment in TBA-reactive substances up to 6.6 mg/ml.

Figure 1 shows the effect of Liv.52 and Liv.100 (1 mg/ml) on reduced glutathione (GSH). In normal condition, GSH content decreased after 20 min as an outcome of auto-oxidation, but in the (1 mg/ml) drug-treated group, the rate of lowering was found to be minimum and the level was maintained up to 40 min. This effect was seen even in the presence of 0.25 mM carbon tetrachloride. The effect of the drugs was found to be appreciable in maintenance of the levels of glutathione at normal (Figure 1).

In the present study, carbon tetrachloride was used as a peroxidative agent, and has been justified to produce free radicals or deplete antioxidant defenses. Carbon tetrachloride is converted to a free radical by hepatic cytochrome P-450.

$$CCl_4 \xrightarrow{\text{Cytochrome P-450}} Cl^{\cdot} + CCl_3^{\cdot}.$$

This radical reacts with oxygen to give a peroxy radical $CCl_3^{\cdot} + O_2 \rightarrow CCl_3O_2$ which is a good inhibitor of lipid peroxidation. Consequently, there is depletion of antioxidant, especially glutathione. Loss of glutathione causes secondary oxidative damage, which can contribute to hepatic failure.

The reason for having employed two different concentrations of CCl_4 (1 mM and 0.25 mM) for the assay

Table 1. Protective effect of Liv.52 and Liv.100 on carbon tetrachloride (1 mM)-induced lipid peroxidation in rat liver

Drug concentration (mg/ml)	0	0.8	1.6	3.3	6.6
Liv.52					
Without CCl_4 'TBARS' nM/100 mg protein	117.08 ± 4.71	116.99 ± 4.20	116.83 ± 3.74	116.69 ± 3.94	116.37 ± 3.62
With CCl_4 'TBARS' nM/100 mg protein	231.85 ± 4.65*	222.90 ± 3.11*	171.97 ± 3.32*	158.47 ± 2.98*	127.36 ± 3.05*
Liv.100					
Without CCl_4 'TBARS' nM/100 mg protein	117.11 ± 4.69	116.78 ± 2.26	116.51 ± 2.35	116.35 ± 2.02	116.24 ± 2.08
With CCl_4 'TBARS' nM/100 mg protein	231.91 ± 4.58*	189.37 ± 1.97*	143.20 ± 2.60*	125.16 ± 2.23*	116.30 ± 2.01*

Values are mean ± SD of 6 animals in each group.
*$P < 0.001$.

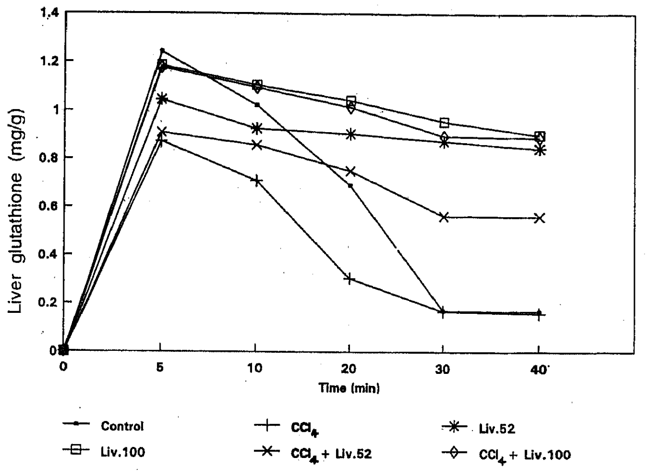

Figure 1. Effect of carbon tetrachloride (0.25 mM), and Liv.52 and Liv.100 (1 mg/ml) on the changes in reduced glutathione content in rat liver. Each point represents mean value of six animals.

of lipid peroxidation (TBARS) and reduced glutathione, is that at higher doses of 1 mM concentration, it released detectable amounts of TBARS but reduced the GSH level (almost to zero). This showed that the oxidation of GSH is followed by lipid peroxidation and therefore, quantitation of reduced GSH would be more sensitive test than TBARS formed.

Carbon tetrachloride-induced peroxidation of lipid in liver homogenate was found to be suppressed by the addition of Liv.52 and Liv.100. The effect was almost completely, inhibited by Liv.100 when compared to Liv.52.

The present results show the dose and time-dependent protective response afforded by Liv.52 and Liv.100 against carbon tetrachloride-induced lipid peroxidation. These results suggest that the drugs act at the lipid peroxide scavenging system through enzyme control or otherwise, by enhanced supply of reduced glutathione[20] that suppressed the deleterious process.

However, the findings indicate that the formulations Liv.52 and Liv.100, contain certain substances capable of preventing lipid peroxidation. Polyphenolic constituents[14,21] of the herbs in the above ayurvedic formulations may be considered to be antioxidants able to react with numerous radicals in cell-free systems, including oxygen and hydroxylic ($OH^{\bullet}$) radicals forming more stable and less reactive compounds[22,23].

To conclude, it is hoped that the beneficial antioxidant nature of Liv.52 and Liv.100 may be applied clinically in the future only after considerable *in vivo* trial with the drugs.

Isotopic compositions of boron in sediments and their implications

P. V. Shirodkar and Xiao Yingkai*

National Institute of Oceanography, Dona Paula, Goa 403 004, India
*Qinghai Institute of Salt Lakes, Xining 810 008, P. R. of China

The abundance and isotopic compositions of boron in sediments from the salt lakes of Qaidam Basin, China have been determined by thermal ionization mass spectrometry of cesium borate. The results show large variations in the isotopic compositions of boron. The observed variations of δ^{11}B, ranging from – 25.2‰ to + 26.08‰ (relative to NBS SRM 951) indicate both an enrichment and depletion in the lighter isotope (^{10}B) in the lake sediments. The lower δ^{11}B values of sediments are mostly closer to the boron isotopic compositions of minerals. Such low δ^{11}B values are attributed to the presence of borates, ulexite and other carbonate minerals in sediments of the salt lakes of Qaidam Basin.

BORON is one of the major elements in seawater[1] and is significantly involved in marine biogeochemical cycles[2,3]. Recent studies have shown that the isotopes of boron act as excellent tracers of geochemical processes[4–6]. The differences in the behaviour of its two stable isotopes, ^{10}B and ^{11}B, result in the isotopic fractionation of boron during its biogeochemical cycling[7] and the extent of this fractionation provides insights into the various processes involved.

Although the isotopic studies of boron are being carried out for the past 2–3 decades, the difficulties involved in the accurate measurement of boron isotopic ratios led to a slow progress in this area. However, the recent advancements in the analytical techniques[8,9] have provided impetus to studies on isotope geochemistry of boron. The isotopic measurements by these techniques have shown wide variations in boron isotopic ratios in nature[10] and indicated distinct differences in the isotopic compositions of boron between the marine, non-marine and terrestrial samples and between seawater, sediments and the upper oceanic crust[11,12].

The hypersaline environments experiencing intense evaporation are excellent sites for isotopic studies of elements as considerable isotopic fractionation occurs during evaporation and precipitation in the brine[13]. The present study is based on the boron isotopic measurements carried out in sediments of the salt lakes of Qaidam Basin, China, from October to December, 1992 to understand their variation and their geochemical implication.

The salt lakes of Qaidam Basin are situated to the north of the Kunlun Tangula mountains in the northwestern part of Qinghai Plateau at an altitude of over 2600 m above sea level. This terrestrial basin (Figure 1), evolved during the Jurassic period[14], is typically a continental potassium-bearing basin with an area of 12×10^4 km^2. It is surrounded by the Altun mountains in the northeast and Kunlun mountains in the south. The streams draining from these snow-capped mountains terminate in a series of saline lakes at the margin of the basin.

The basin experiences a typical continental climate with difference in day and night temperatures, reaching as high as 30°C. The climate is arid and cold with an annual precipitation less than 50 mm and annual evaporation far exceeds precipitation. Due to the low air temperatures, high aridity and strong winds, the waters in these lakes have turned into brines.

Sediments were collected from 22 salt lakes in the Qaidam Basin (Figure 1) during 7 July–10 August, 1992. After collection, the brine was drained out and the sediments were oven dried at 60°C. The dried sediments were finely powdered and sieved through a standard 100 mesh. A known quantity of the sieved sample was treated with a minimum quantity of dilute HCl (< 0.1 N). The acid-washed sediments were filtered and the filtrate was preserved for isotopic measurements. The residue was then washed with distilled water and again filtered. The filtrates were mixed together and made up to 50 ml. Boron contents in the filtrates were determined through mannitol-alkalimetry titration[15]. A known quantity of the filtrate was used for the extraction of boron by ion-exchange for isotopic measurements[16].

A mixture of weakly basic anion exchange resin in HCO_3^- form and a strongly acidic cation exchange resin in the H^+ form was poured into a special glass column. The boron-containing solutions were slightly acidified with HCl before passing through the column. After shaking for 7–10 min, boron was eluted with 60 ml high-purity water. The yield of boron recovered from each sample was more than 98%. After elution, the ^{11}B/^{10}B ratio was measured by a mass spectrometer, model VG 354, based on thermal ionization mass spectrometry of cesium borate using graphite as a substrate

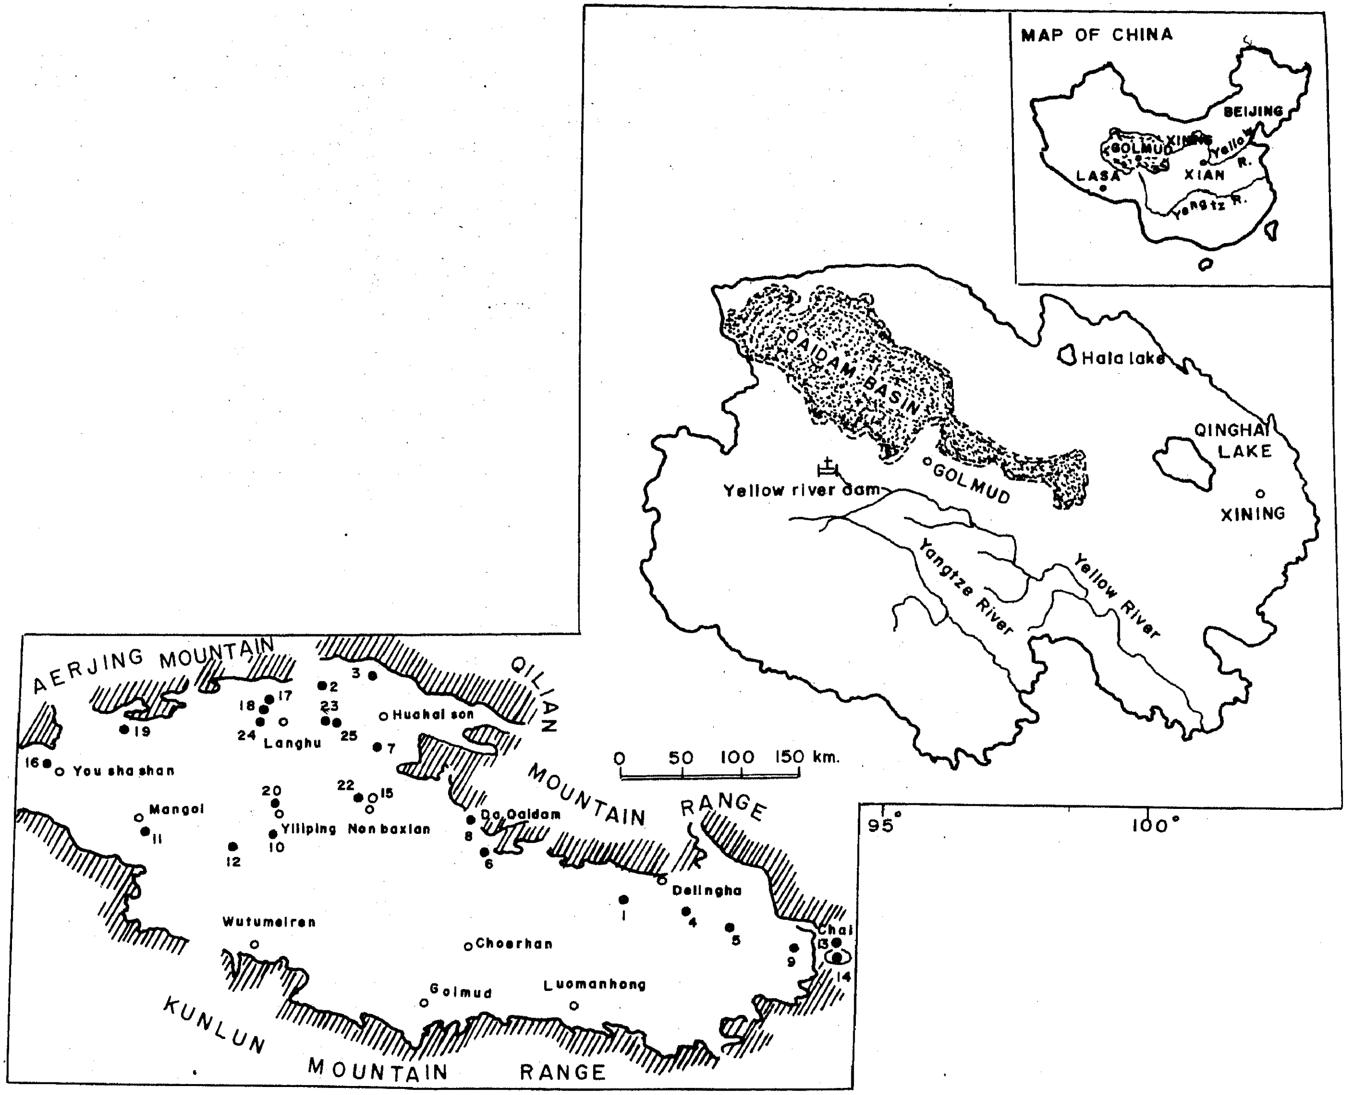

Figure 1. Location of Quidam Basin and the salt lakes in Quidam Basin, China.

for loading[8]. The $^{11}B/^{10}B$ ratio of NBS SRM 951 was first obtained and was found to be 4.04362 ± 0.0011. The isotopic ratios of the samples were then expressed as del values (per mil deviation, $\delta^{11}B$, relative to NBS SRM 951 Boron Standard value of 4.04362), according to the equation

$$\delta^{11}B(\text{sample}) = [(^{11}B/^{10}B)\text{sam}/(^{11}B/^{10}B)\text{std} - 1] \times 1000,$$

with a precision of 0.023% (95% confidence limit) for the standard solution while for the samples, the precision was 0.03%.

The $^{11}B/^{10}B$ ratios of sediments varied from 3.9416 to 4.1491 with a mean of 4.0431. The $\delta^{11}B$ values were found to range from $-25.21‰$ to $+26.08‰$ (Table 1).

The main components of the salt lake sediments were halite, gypsum and clay minerals. The clay minerals constituted 5–20% of the sediments; of these, the most abundant were illite (58–78%) and kaolinite (11–42%) (Table 1).

The isotopic compositions of boron showed low (negative) values for most of the sediments from the salt lakes of Qaidam Basin. Even the higher (positive) values of $\delta^{11}B$ of sediments were much lower than those of the overlying brines, collected simultaneously from the respective salt lakes[17]. This reveals the effect of isotopic fractionation of boron wherein the lighter isotope, ^{10}B, is preferentially removed from the overlying brines to sediments. The fractionation of boron has been attributed to its tetrahedral species, $B(OH)_4^-$ which is enriched with ^{10}B (ref. 4). Due to the greater affinity of ^{10}B for solids, the borate anion gets preferentially adsorbed onto solid substances when dissolved boron comes in contact with solids[18].

Table 1. Abundance and isotopic compositions of boron and the clay minerals in Salt Lake sediments

Location (lakes)	Boron (mg/kg)	Clay mineral (%)			$^{11}B/^{10}B$	$\delta^{11}B$

I: Interstitial brine.
NA: Not analysed.

Various factors such as pH, temperature, ionic strength, boron concentration of solution and the nature of minerals affect the fractionation of boron[4,7,12]. The most important factor affecting the speciation of boron is pH as it controls the relative proportion of the two dominant species – $B(OH)_3$ and $B(OH)_4^-$ (ref. 19). The abundance ratio of $B(OH)_3$ to $B(OH)_4^-$ in turn influences the $\delta^{11}B$ in sediments and minerals. Ingri *et al.*[19] showed that within the pH range of 5–12, the $B(OH)_3$ to $B(OH)_4^-$ ratio decreases as the proportion of $B(OH)_3$ decreases with increasing pH. The pH values of the overlying brines in these lakes[17] were within a comparable range (4.43–8.9). Such a range leads to variable mole fractions of $B(OH)_3$ in brines and thus to different $^{11}B/^{10}B$ ratios and $\delta^{11}B$ values in sediments.

The $\delta^{11}B$ values of the salt lake sediments in this study (Table 1) are much lower than those reported for the marine and nonmarine sediments (the nonmarine environment in this case refers to the freshwater environment). However, the salt lakes of Qaidam Basin represent an evaporative environment. In such an environment, boron is not significantly removed by precipitated salts but remains in the brine and gets concentrated in evaporitic clay minerals rich in magnesium, as the tetrahedrally coordinated boron[20,21]. The studies on the geochemistry of boron[3] have shown that the adsorption of boron takes place on sediment particles and the clay minerals are very significant for adsorption. This adsorption leads to isotopic fractionation of boron[22].

The clay minerals of the salt lake sediments comprise 58–78% illite, 11–42% kaolinite and 11–17% chlorite (Table 1). The adsorption of boron on these minerals therefore contributes to the lowering of $\delta^{11}B$ values observed in this study. Apart from this, boron is also taken up by boron minerals and the isotopic composition of borate salts is dependent on their atomic configuration and the proportion of boron species in the mineral[23]. The boron (as borate) content of some of its minerals has been given as (100% BO_4) boracite, (66% BO_4) colmanite, (60% BO_4) ulexite and (50% BO_4) borax. These minerals are always depleted in the heavier isotope ^{11}B relative to that in the parent brines[24].

Similarly, different minerals are found to have different boron isotopic composition values, e.g. authigenic marine silicates (– 38‰); the adsorbed boron onto marine sediments (–25‰) and the modern marine biogenic carbonates (– 7 to – 25‰). The boron isotopic compositions of some of the boron minerals are: – 4‰ (borate); – 12.8‰ (ulexite) and from – 17.24 to – 23.67‰ (pinnoite)[12,18,24]. As seen from our values in Table 1, the $\delta^{11}B$ values of the sediments from the Tuosu lake (– 5.05‰), Nanbaxian lake (– 4.43‰) and the Kunteyi lake (– 4.71‰) are closer to those of the borates (– 4‰). So also, the $\delta^{11}B$ values of the sediments from potassium lake (– 16.2‰) and the Kunteyi lake (– 16.20‰) are closer to that of ulexite (– 12.8‰) while the $\delta^{11}B$ values of many other lake sediments fall in the range for carbonates.

The main boron minerals found in these lake sediments are ulexite, pinnoite, borax and other potash minerals of chloride and sulphate type. The chloride minerals are carnallite, sylvite, halite and bischofite, whereas the sulphate type are mirabilite, picromerite and polyhalite which are always found in association with epsomite, bloedite, mirabilite or gypsum[25–27]. Oi *et al.*[23] observed that the minerals of marine origin have higher $^{11}B/^{10}B$ ratio and higher $\delta^{11}B$ value than those of the nonmarine origin and the $^{11}B/^{10}B$ ratios of minerals from the same geologic origin depends upon the crystal structure. A correlation exists between the crystal structure of the mineral and its $\delta^{11}B$ values. They attributed it to the reduced partition function ratios (RPFRs) of the two species of boron based on the general theory of isotope effects. The RPFR of the $B(OH)_3$ species is larger than that of the $B(OH)_4^-$ and the mineral having the higher $B(OH)_3/B(OH)_4^-$ ratio has larger $^{11}B/^{10}B$ ratio and larger $\delta^{11}B$ value at any temperature. Thus it has been realized that the abundance ratio of $B(OH)_3/B(OH)_4^-$ in the solution has a profound effect on the boron isotopic composition of the mineral formed. The varying pH of the overlying brines of these salt lakes (4.43–8.90) may therefore result in differences in the mole fraction of $B(OH)_3$ and $B(OH)_4^-$ giving rise to different values of $\delta^{11}B$ for the minerals. So, the slight variation in $\delta^{11}B$ values observed in our study compared to that of the boron minerals given above, is due to varying pH of the brines of the salt lakes and different origin. These $\delta^{11}B$ values can therefore be attributed to the presence of borates, ulexite and other carbonate minerals and as such assume greater importance in the exploration of minerals and the characterization of environmental samples.

In conclusion, the boron isotopic compositions of the salt lake sediments indicate the presence of borate, ulexite and other carbonate minerals. During the formation and transformation of minerals in sediments (particularly boron minerals), substantial element exchange takes place. This leads to the isotopic fractionation of boron. So, the boron isotopic study of sediments can give an understanding of sediment diageneses. Measurement of the boron isotopic composition of sediments by mass spectrometry can serve the dual purpose of detecting the minerals and the isotopic composition of the sample.

PERSONAL NEWS

Professor Paul Erdős (1913–1996)

An obituary

Professor Paul Erdős (pronounced Airdosh) was born in Hungary on 26 March 1913. It is reported that even at the age of 3, he had invented negative numbers by himself when he set out to answer the question. How much is 250 degrees below 100 degrees? His answer was 150 degrees below zero. A few years later he amused himself by finding out how long does a train take to reach the sun. He had two elder sisters both of whom died of scarlet fever a few days before he was born. So his mother took very good care of him. He never got married and his mother helped him by taking care of his publication list and so on. She travelled with him wherever he went and Erdős was extremely sad after she passed away. His was a life dedicated completely to mathematics. He was so prolific that he had more than 1500 important papers to his credit. He was so versatile that he could contribute significantly to (almost) any mathematical problem. No wonder if, I call his contributions as 'Erdőssian Mathematics'. Some people who found that it was difficult to follow his work, say that he does not do mathematics. For some time I thought that such people invented the concept 'Erdős Number' to make fun of the fact that he writes too many joint papers (the Erdős number of a collaborator with him is 1, that of a collaborator's collaborator is 2 and so on). But later on I found (from A. Ivić) that this concept was invented by Erdős himself (for some purposes). Mathematicians would look upon Erdős as god himself and consider a close association with him as an indication of their merit (close association with him will mean a small Erdős number) and greatness. Erdős' mathematics, so terse and at the same so attractive, is described rightly by Ernst Straus (who worked both with Einstein and Erdős) as follows:

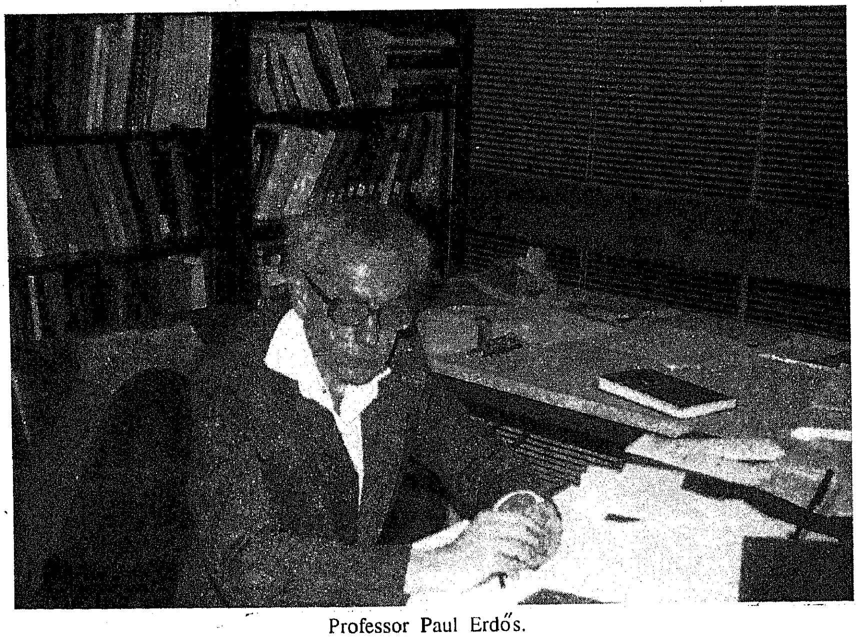
> 'In our century in which mathematics is so strongly dominated by "Theory Doctors" he has remained the prince of problem solvers and absolute monarch of problem posers.'

Looking at the vast number of papers which he has written one cannot help comparing him to L. Euler and looking at the depth and attractiveness of Erdőssian mathematics one cannot deny that he is 'in some sense' the greatest mathematician of this century. Judged from whatever angle I agree with R. Graham that he is certainly amongst the top ten in this century. He had 458 collaborators (that is those with Erdős number 1) and about 4500 with Erdős number 2 and about 100 papers will be published by his collaborators after his death. I am proud to say that I have Erdős number 1 (about which I will say in a later section). On the whole I can say that many subjects will emerge by his contributions.

Some reminiscences

I had heard of Erdős as an extra ordinary mathematician (and I had looked at some of his papers early in my research career) and I was longing to meet him (although I never expected to have that golden opportunity). In 1970–71 I was a neighbour of C. Hooley (at Princeton, Institute for Advanced Study) and he came to know that Erdős will be in New York Academy of Sciences for a few days. He telephoned Erdős and arranged for a meeting with him. He drove me to New York and we were very happy to meet Erdős and his mother. Erdős gave a lunch party to us during which he introduced us to his mother. Thereafter I used to write to him frequently and he promptly replied all my letters. At this point I would like to say that no matter whether you are amateur or a professional he would promptly reply your letters (he wrote about 15 to 20 letters a day). Every time it would be a friendly letter and suggestion of some mathematical problems. Another point about Erdős address: he never used to stay at any place for more than a week and he has travelled practically throughout the world. I always wrote to his Hungarian address. Hungarian Academy used to redirect my letters to his address. The letters would have to travel throughout the world to reach him. What is very amazing is that he remembered what he wrote to people. Each letter to them would contain suggestion of several problems, contributions for collaborative work besides enquiring welfare of family members and friends.

He has visited TIFR twice. On one occasion guest house was (luckily for us)



Professor Paul Erdős.

---

*This obituary is based on two reports on this topic (namely obituary) one from Brestilov Novak and another from Aleksander Ivić. In addition, it contains something about Professor Erdős which I report from my experience.

not available. We (my family and I) had him as our guest at our residence. We felt very much honoured and we will keep it as a valuable treasure in our minds the memory of his visit to us. He would work till 2 at night drinking frequently a cup of black coffee. His habit was to work almost round the clock. (Also he liked the food in our house.) Another friend in TIFR closely connected with him is N. M. Singhi.

Encouragement to E. Szémerédi

As has been said before, Erdős used to encourage difficult attractive research very much. He used to state such problems and announce prizes for solutions. Many youngsters have received prizes from him. I once spoke to him about the work of H. Maier and he told me that Maier had knocked off several prizes from him. (H. Maier, known for his highly original work on large and small differences between consecutive primes and so on, is at present a professor at ULM in Germany.) Once Erdős had proposed the following problem:

Let $k \geq 3$ be any fixed integer and N a variable integer. Let S_1 be maximal subset of integers from the set $\{1, 2, \ldots, N\}$ with the property that no k integers of S_1 are in arithmetical progression. Let $M = M(k)$ be the number of integers in S_1. Then

$$\lim_{N \to \infty} \frac{M}{N} = 0.$$

This was solved by E. Szémerédi in an outstanding paper. Erdős proposed him for Fields Medal. But much to the dismay of the world he was not selected for Fields Medal. Erdős was annoyed. But he did not keep quite. In the same gathering of IMU (International Congress of Mathematicians) he gave \$2500, a medal and a citation to Szemeredi. (Note also that \$2500 exceeds the amount of the Fields Medal.) No individual has struggled all by himself and upheld the cause of deep and attractive mathematics as Paul Erdős.

A mathematician with no home, no job, a great seeker after properties of $1, 2, 3, \ldots$, Erdős would travel from place to place bearing the torch of knowledge and he would propose problems, announce prizes and help people to progress in their work. (At this point one remark: He remembered references to many (important) papers including his own, so much so that he may be known as a mobile encyclopaedia. People may think that he travelled with a huge luggage but his only luggage was a half empty small size suit case.) I mention a few attractive problems of his with prizes.

(1) Let $1 = b_1, b_2, b_3, \ldots$ be any increasing sequence of integers with the property that

$$\sum_{n=1}^{\infty} \frac{1}{b_n} = \infty.$$

Then given any fixed integer k there exist $k(\geq 3)$ distinct integers b_ν $(\nu = n_1, n_2, n_3, \ldots, n_k)$ forming an arithmetical progression. (Prize \$20,000).

(2) Let p_n denote the nth prime. Then prove or disprove that

$$\lim_{n \to \infty} \frac{p_{n+1} - p_n}{\log n \ \log\log n \ \log\log\log n} > 0.$$

(Prize \$20,000).

He would also increase the prize from time to time if a problem remained unsolved for longer periods.

Some contributions of Erdős

It is practically impossible to touch upon all the ≥ 1500 papers of Erdős. A. Ivić remarked that he would pity the person who prepared the bibliography of all the papers of Erdős. (Suffice to say that all these papers involve considerable skill and originality.) I would single out three discoveries of Erdős.

(a) G. H. Hardy and J. E. Littlewood could prove that

$$\lim_{n \to \infty} \frac{p_{n+1} - p_n}{\log n} < 1$$

(that the above limit is ≤ 1 is a trivial consequence of the prime number theorem which asserts that $p_n(n \log n)^{-1} \to 1$ as $n \to \infty$) only on the assumption of a very difficult *unproved hypothesis* called Generalized Riemann hypothesis. Erdős succeeded in proving this without using any unproved hypothesis. He achieved it by a very ingenious use of Brun's Sieve.

(b) The prime number theorem stated just now was proved (by methods independent of theory of functions of one complex variable) by P. Erdős and A. Selberg independently of each other.

(c) For integers $n(\geq 2)$ let $\omega(n)$ denote the number of distinct prime factors of n (for our purpose it does not matter if the prime factors are counted with multiplicity). Let $f(n)$ be any positive function which $\to \infty$ as $n \to \infty$. Let $F(x)$ denote the number of integers $n \leq x$ with the property

$$|\omega(n) - \log\log n| \leq f(n) \sqrt{\log\log n}.$$

Then G. H. Hardy and S. Ramanujan proved (for the first time after conjecturing it) the result that

$$\frac{F(x)}{x} \to 1 \quad \text{as} \quad x \to \infty.$$

P. Erdős and M. Kac put forth the best of their talents and proved by an ingenious method the following result (which says a lot more about the theorem of G. H. Hardy and S. Ramanujan). Let C_1 and C_2 be any two real constants with $C_1 < C_2$. Let $F(x, C_1, C_2)$ denote the number of integers $\leq x$ with the property

$$C_1 \sqrt{\log\log n} \leq \omega(n) - \log\log n \leq C_2 \sqrt{\log\log n}.$$

Then

$$\frac{F(x, C_1, C_2)}{x} \to \left(\int_{-\infty}^{\infty} e^{-u^2} \, du \right)^{-1} \left(\int_{C_1}^{C_2} e^{-u^2} \, du \right).$$

(A passing remark: An Indian who has studied this theorem and worked out some variants of this theorem is A. Krishnaswamy.) Erdős–Kac theorem forms the foundation of a deep aspect of probabilistic number theory.

Encouragement to me and some others

Let u and k be positive integers and let $P(u, k)$ denote the greatest prime factor of $(u+1)(u+2)\ldots(u+k)$. One of the early interests of P. Erdős is what I call Sylvester–Erdős Theorem (Sylvester was the first to prove it and Erdős supplied a simpler proof). It states that

$$\min_{u \geq k} P(u, k) > k\,.$$

Note that this is a two-variable generalization of Chebyshev's theorem that $P(k, k) > k$ (which is nothing but the well-known Bertrand's postulate). Erdős also proved that

$$\min_{u > k^{3/2}} P(u, k) > \frac{1}{3}\, k \log k$$

provided k exceeds a large constant (we make from now on this hypothesis about k).

Independently of all this (not knowing this) I considered the special case $k = [u^{\frac{1}{2}}]$ and proved that $P(u, k) > u^{\lambda}$ with $\lambda = \frac{1}{2} + \frac{1}{13}$ by using Selberg Sieve and Vander–Corput sums. Erdős encouraged me to consider the case $u = [k^{\frac{1}{100}}]$ and things of that kind and I was led to prove that (apart from ε's δ's)

$$\min_{u \geq k^{3/2}} P(u, k) > k \log k\,.$$

However it was R. Tijdeman who sharpened (by Halberstam–Roth method, completely different from mine) the lower bound to $2k \log k$. Using (A. Baker's method on linear forms) myself and T. N. Shorey (improved Tijdeman's result to the fact that 2 can be replaced by any constant) and (using I. M. Vionogradov's methods) M. Jutila could improve it further by combining it with myself T. N. Shorey procedure. The final outcome is

$$\min_{u \geq k^{3/2}} P(u, k) > \mu k \log k \log\log k (\log\log\log k)^{-1}\,,$$

where $\mu > 0$ is a positive constant (we have the result $p_{n+1} - p_n = O(p_n^{5/8})$ which implied that if $k \leq u \leq k^{3/2}$, $P(u, k) > u$). This is a very good achievement (the best known to-day) due to myself, T. N. Shorey and M. Jutila. Needless to say that Erdős was encouraging all the time at all stages of our work.

Another problem concerns is generalization of Mirsky's result that the number of square free numbers s and such that

$$2n = p + s \; (p - \text{prime})$$

is asymptotic to a constant (>0) times $n(\log n)^{-1}$. Myself and G. J. Babu considered the number of solutions in integers (with certain property be stated below) satisfying

$$2n = p + s$$

is asymptotic to a constant (>0) times $n(\log n)^{-1}$. The property is this: Let $b_1, b_2, \ldots$ be away increasing sequence of positive integers (with $b_1 \geq 2$) such that for any two distinct integers i, j we have $(b_i, b_j) = 1$ and

$$\sum_{j=1}^{\infty} (\varphi(b_j))^{-1} < \infty\,.$$

(The numbers s are assumed to be not divisible by any b_j.) We had to introduce some further conditions and Erdős removed practically all the conditions. The result was a joint paper by myself, G. J. Babu and Erdős. In another joint paper we considered also further relaxation of conditions and obtained the lower bound of the same order instead of an asymptotic formula. All this was possible only because of various letters from Erdős.

I should mention that he has joint papers with T. N. Shorey, R. Balasubramanian and a complete account of these contributions would require a longer article.

Erdős was an honorary fellow of the Hardy–Ramanujan Society besides having many other honours throughout the world. He was on the editorial boards of many journals in the world (*Acta Arithmetica*, *Journal of Combinatorics*, *Bulletin of the Calcutta Mathematical Society*, *Journal of the Indian Mathematical Society*, and so on). His service to mathematics is so great that we feel that the world is not the same without him. In fact there exists in the minds of some of his followers a fact that they belong to the Erdős International Academy of Mathematics, Erdős International University and so on. Professor A. Ivić is one of them. Erdős passed away on 20 September 1996 in Warsza, Poland.

Annual Review of Pharmacology and Toxicology 1996. Arthur K. Cho (ed.). Annual Reviews Inc., 4139 El Camino Way, Palo Alto, California 94303-0139, USA. Vol. 36. Price: USA $ 52, elsewhere $ 57. 719 pp.

The Annual Review of Pharmacology and Toxicology, like other annual reviews of medical sciences, has a long tradition of publishing good articles on selected topics and/or areas relating to different fields of medical sciences, thereby highlighting the important developments in different areas of research. This volume has 26 review articles that can be broadly classified into 8 groups: Prefatory chapters; Antimicrobial and antiviral chemotherapy; Cancer chemotherapy and immunopharmacology; Cardiovascular and endocrine pharmacology; Environmental and industrial pharmacology and toxicology; Mechanisms of drug actions, Neuro and behavioral pharmacology.

The volume begins with the first prefatory article written by Nobel laureate Sir James Black, who contributed to the discovery of propranolol and cimetidine. In this chapter, Black adumbrates the way his ideas about pharmacological analysis have developed over 40 years and explains concepts, models and techniques used in analysis and also a need for the future development. The central theme is how the development of simple mathematical model has assisted in the interpretation of drug action. The second prefatory article 'A career in toxicology' is interesting and useful to young toxicologists, who could learn from the varied exciting experiences of R. A. Neal. The author finally states that there is a distorted public perception of risks posed by environmental chemicals and there is an urgent need for toxicologists to take a more active role in objective evaluation of the available data published by the scientists, print and electronic media.

In the first group, three chapters discuss advances made in the understanding of antimicrobial and antiviral chemotherapy. In the 1980s, a novel form of gene regulation was discovered in prokaryotes whereby translation of a specific mRNA into protein was suppressed by its hybridization and binding to a counter transcript, i.e. an RNA transcript in opposite orientation to the mRNA. Investigators are now making progress in utilizing this concept of nature in the development of a new class of therapeutic agents called antisense. Early reports from *in vitro* animals as well as human trials are quite exciting. Crook and Bennet describe the progress in the development of antisense oligonucleotides as pharmacological and therapeutic tools. Multidrug resistance represents a major obstacle in the successful chemotherapy of cancer. Studies have demonstrated that P-glycoprotein appears to play an important role in drug resistance. Bellamy in 'P-glycoprotein and multidrug resistance', suggests that one should not over-look other probable mechanisms such as increased detoxification, enhanced ability to repair DNA damage, alterations in cellular metabolism, failure to undergo apoptosis may also be operating. Despite several classes of promising new anti-HIV agents, the clinical emergence of drug resistance variants of HIV has severely limited the long term effectiveness of non-nucleoside drugs. Critical mutations in the RT and PR genes in resistance virus have been identified. Erikson and Burt feel that these insights will have definite implications in design of new drugs and therapeutic strategies to combat drug resistance to AIDS.

In the article 'Molecular mechanisms of toxicant-induced immunosuppression', Hosapple *et al.* describe the role of second messengers in immune regulation and how changes in intracellular signalling by immunotoxic agents (cannabionoids, polyaromatic hydrocarbon (PAHS) etc.) result in immune disfunction.

There are three excellent articles in cardiovascular related area. In 'Angiotensin receptors and their therapeutic implications', Griendling *et al.* describe the current concepts on angiotensin receptor classification, antagonist and their therapeutic utility. At least 30 different phosphodiesterase enzymes have now been identified in mammalian tissues and cells, many of which are products of separate genes. Polson and Strada describe the cardiovascular potentials of various PDE inhibitors. In the article 'Cardiac actions of antihistamines', R. L. Wossley cautions the clinicians about the propensity of some of the new generation antihistamines like terfenadine and astemizole to induce life-threatening arrhythmias and alerts the essentiality of investigating the cardiac toxicity of older antihistamine, which are still under clinical use.

Insulin controls organismal and cellular physiology of numerous intracellular signals. Despite intensive investigations, the basic molecular mechanism of insulin action on glucose metabolism is still elusive. In the review article, 'Insulin signal transduction and the IRS proteins', Myers and White give detailed aspects of molecular mechanisms, in particular the role of IRS protein in insulin action. This is truly an excellent article, well-annotated and of value to anybody working in diabetes research either in the laboratory or in the clinic. Progesterone plays a crucial role in the mammalian reproduction that is: initiation and maintenance of pregnancy. Some of the antiprogestins like mefipristone have strong affinity to both progesterone and glucocorticoid receptors. Spitz *et al.* describe an exciting therapeutic potential of these molecules at low doses for the treatment of endometriosis, uterine myoma, inducing abortion, treatment for steroid-dependent tumours and contraceptive. Along with the impressive body of evidence on the molecular mechanisms of estrogen, Yager and Liehr discuss in 'Molecular mechanisms of estrogen carcinogenesis' the mechanisms of estrogen carcinogenesis with a focus on carcinogenic potentials of estrogen metabolites.

Breast cancer has claimed a unique place in the public consciousness. Over the past decade, and especially within the past few years, breast cancer has become probably the single most discussed medical topic of all – more so even than AIDS and cardiovascular diseases. In recent years we have witnessed a barrage of articles and debates and programmes and information about breast cancer epidemics. The real turning point came in 1990 when scientists finally proved the existence of a gene called BRCA1 which if damaged could predispose women to developing breast cancer. In 'Breast cancer and environmental risk factors', Wolf *et al.* present the epidemiological evidence for breast cancer risk from exposures to chemicals and physical agents in the environment and relevant corollary studies in laboratory animals. Hoyer and Siper, in 'Assessment of follicle destruction in chemical-induced ovarian toxicity' discuss the various aspects of 4-vinyl cyclohexene-induced ovarian toxicity.

There are three excellent articles in the area of molecular mechanisms of action of drugs and chemicals. The first one looks into the role of G-protein molecular mechanisms in signalling process. Results obtained in the past few years have greatly enhanced and modified our understanding of G protein-mediated transmembrane signalling processes. There is a large body of evidence showing that many G protein-coupled receptors do not signal by activating only one G protein to generate one intracellular signal. Possibly more often, different G proteins are activated in one receptor to generate multiple intracellular signals. Gudermann *et al.* explain the G-protein-mediated complex signal network at each transduction level, i.e. receptor, G-protein and effector. In addition to this, Exton in 'Regulation of phosphoinositide phospholipases by hormones, neurotransmitter and other agonists linked to G-proteins' describes the mechanism by which agonists activate phospholipase isozymes. The molecular cloning technique has permitted identification of ten novel isoforms of mammalian adenylyl cyclase, which are membrane bound activated by alpha subunit of G-alpha and by the diterpene forskolin. Sunahar *et al.* review the current understanding of multimodel regulation of adenylyl cyclase system and cAMP synthesis.

There are nine reviews under neuro and behavioral pharmacology. Progressive degeneration of a subset of neurons is the pathologic hallmark of adult-onset neurodegenerative disorders such as Alzheimer's disease, Parkinson's disease and amyotrophic lateral sclerosis. A growing body of evidence points to the involvement of free radicals in mediating neuronal death in these diseases. Simonian and Coyle review advances made in understanding the intracellular pathways involved in free radical generation and how free radicals contribute to selective neuronal degeneration in these disorders. An approach to increase defense mechanisms against free radicals may be an important pharmacological strategy to show or halt neuronal degeneration. Lipid vs protein theory of alcohol action in the nervous system is the subject of one of the most long-standing debate controversies of biology. Once again in this review, People *et al.* discuss both lipid and protein theories of alcohol's action and in addition, its effects on neurotransmitter-gated ion channels are also looked into. Exocytosis is an ubiquitous mechanism for secretion of intercellular chemical messengers. Our understanding of the molecular mechanism is still ambiguous. Augustine *et al.* review a number of perturbation strategies and summarize what this approach has taught us about the functional roles of protein in exocytosis and also molecular model of protein dynamics during exocytosis. Enormous advances have been made toward the understanding of nociception and this definitely modified our approach in discovering future analgesic drugs. Both Dray and Urban feel that new targets including receptors, enzymes transport systems, gene regulation will be the future target for developing antinociceptive agents. Generally opioids exert their pharmacological actions through three opioid receptor classes μ, δ, k, which are identified through molecular cloning technique. Despite this advancement, our knowledge about their involvement in pharmacological actions is not clear. In 'Opioid receptor types and sub-types', Zaki *et al.* describe the concept of multiple δ opioid receptor subtypes which might be helpful in our understanding and development of selective pharmacotherapeutics.

The concept that clonidine, a centrally acting antihypertensive, might be interacting with a receptor recognizing its structure as an imidazoline was proposed by Bousquit *et al.* in 1984. Imidazoline receptors constitute a family of noradrenergic high-affinity binding sites for a clonidine, idazoxan and allied drugs. Although these receptors are not yet cloned, there are abundant biochemical, pharmacological and biological data to indicate that they and α adrenergic receptors are distinct molecular entities. Many questions related to the molecular, cellular, pharmacological and functional relevance of the I receptor family and its endogenous ligands await cloning of the receptor and establishments of the structure of other endogenous ligand. Anabolic androgenic steroids have become more widely used and abused not only by the elite athletes but also by non-athletes for cosmetic purpose as well as promoting aggressive behaviour. Luckas in 'CNS effects and abuse liability of anabolic androgenic steroids', feels that at least the former knows the danger and side effects while the latter tend to be more ignorant of facts. As there are no reliable animal models for characterizing the abuse liability and physical dependence potential of this class of drugs, Lukas feels a better understanding of the CNS effects and abuse liability of anabolic androgenic steroids may come from newly emerging studies of neuroactive steroids and brain imaging technologies. In addition, in 'Pathophysiological basis of vulnerability to drug abuse' Piazza and Moal discuss the role of an interaction between stress, glucocorticoids and dopaminergic neurons. Nicotinic cholinergic systems are believed to be important in memory-enhancing effect and there is a loss of cholinergic innervation from the basal forebrain in pathologies that affect memory, such as Alzheimer disease. The definitive demonstration that nicotine potently enhances transmission in the hippocampus is unquestionably an important step towards recalling nicotine as a powerful modulator of memory. In 'Pharmacology of nicotine', Benovitz describes addictive and therapeutic potentials of nicotine for the treatment of Alzheimer's disease, ulcerative colitis, Parkinson's disease, Tourette's syndrome, sleep apnea, and attention-deficit disorder.

Unusually there are no reviews on allergy, inflammation, respiratory, gastrointestinal, renal pharmacology, pharmacokinetic and natural product topics. It is difficult for editors to cover all topics of medical interest. Nevertheless, the editors have made a valiant attempt to provide the readers with a comprehensive and thorough review of the current topics in pharmacology and toxicology. All chapters in the review are well written, comprehensive to the general and special readers. Thus this annual review provides an important and invaluable source of literature and data.

Dr Reddy's Research Foundation,
Bollaram Road, Miyapur,
Hyderabad 500 138, India

The Natural Science of the Human Species: An Introduction to Comparative Behaviour Research – The 'Russian Manuscript' (1944–1948). By Konrad Lorenz. Edited by Agnes von Cranach. Translated by Robert D. Martin. MIT Press 1996, pp.337 US $35.

This book, the first that the Nobel Laureate ethologist Konrad Zacharias Lorenz (1903–1989) wrote, is his last to be published. It was written in the period 1944–1948 while he was a prisoner-of-war in Armenia. The manuscript, called the 'Russian Manuscript', consisted of about 750 pages. As there was no paper available he ironed old cement sacks and used them to write on, improvizing his own ink of potassium permanganate, steel nibs and occasionally bird quills. Apart from scarcity of writing materials he wrote under extremely harrowing circumstances without a desk, poor lighting conditions and freezing temperatures in winter. The book is a tribute to human heroism and perseverance.

This book has much to offer to students of history, sociology of science and to those interested in the development of scientific ideas. There is also something for philosophers in it, even though it must be pointed out that Karl Popper vehemently disagreed with Konrad Lorenz's interpretation of Kant as contained in this book. Its central construct is to give a Darwinian and evolutionary explanation of the philosophical writings of Immanuel Kant. From 1940 until he was drafted into war service, he had briefly shared with Edvard Baumgarten the Professorship of Psychology at the Albertus University of Koenigsberg, a post previously held by Immanuel Kant. The best part of the book is taken up in reconciling the real world and the *a priori* or the phenomenal worlds of Kant. For Kant there were two distinct worlds – the real world outside and the internal world with *a priori* schemata that influence and filter our perceptions. Therefore, for Kant there was no comprehensible and logically tangible relationship between the objective world and the intelligible world, comprising only those *a priori* schemata that create images of objects in our perceptual world. Lorenz is trying to recognize and establish a connection between the two worlds. All *a priori* knowledge consists of evolved genetic representations which are adaptive predispositions that allow humans to make sense of the myriad visual and sensory stimuli originating in the outside world. Those acquainted with Lorenz's work will recognize that he has advocated in all his books and writings the same idea for non-human animals. Thus arose his concepts of 'fixed action patterns' and 'innate releasing mechanisms' which enable animals to instinctively respond to appropriate eliciting stimuli the first time they are confronted with them.

The 'Russian Manuscript' travelled with its author during his entire career, first in Vienna and later as the Director of the Max-Planck-Institutes for Behavioural Physiology in North Germany and in Seewiesen, Bavaria. The manuscript unaccountably disappeared sometime in the 1960s and was discovered by his daughter Agnes von Cranach in 1990 in the family home in Altenberg near Vienna. The wealthy orthopaedic surgeon Professor Adolf Lorenz was a remote and authoritarian father. He thoroughly disapproved of Konrad's adolescent passions (to marry a young woman of his choice, which he later did, and to work with animals). The father was not even impressed with his first landmark paper on the behaviour of a tame jackdaw and openly said that the only good bird was one on the table ready to be eaten!

The real question is, what scientific value could a book written fifty years ago have today. This book cannot even be viewed as a zeitgeistdokument since it does not contain contextual references. Much of the ideas and material found here have found their way into books that Lorenz later wrote *On Aggression, Die Rückseite des Spiegels* and his textbook *The Foundations of Ethology*. In fairness Lorenz did not want to publish this book in the form it then had (and apparently still has today) nor had he decided on a definitive title. The present title is quaint and does not give even an inkling about its rather rambling contents. It does appear, however, that Lorenz had already conceived in his mind the many and varied conceptual contributions he would be making over the next three decades. This in itself is a fascinating phenomenon. But then Lorenz's working methods were most unusual even for an ethologist. John R. Krebs had this to say of his empirical research style: 'He rarely did replicated, controlled experiments, but reached conclusions, sometimes correct and sometimes, with the benefit of hindsight, probably incorrect, on the basis of careful and detailed observation of the spontaneous behaviour of animals living around him'. An unwitting but apt comment was made many years later at Seewiesen, by F. Schutz, who once asked Konrad during a seminar: 'Is that something that actually happens or is it just something you saw?'.

It is very unlikely that the book under review will be anywhere as popular as some of his earlier charming books such as *King Solomon's Ring* and *Man Meets Dog*, even though the writing style is already quintessential Lorenz (samples: p. 19, Kants premise that there is no relationship between these two worlds is incorrect. p.20, The infinite quest for knowledge that drives the natural sciences fundamentally prevents us from making any voluntary concessions to agnostics. We simply do not believe that there is anything in the universe that is fundamentally unknowable. p. 187, It was Kant who coined the delightful sentence: there are two things that never-endingly fill the human spirit with wonder – the starry sky above and the moral law within. p. 247... Heinroth habitually referred to philosophy as the pathological idling of innate human functions intended for an understanding of nature etc).

Lorenz is preoccupied in several chapters on vitalism, mechanism and their implication for comparative behaviour research (ethology). Fortunately for biology these isms and schisms have been subsequently excoriated by the scientific insights made by developmental biology, genetics and molecular biology. There is delightful chapter written with much feeling on 'Animal keeping as a research method'. Even his stern parents had allowed him as a boy to maintain at home a bestiary which included invertebrates from the Danube, tropical fish species, amphibians and reptiles, hand-raised birds, night herons, ravens, little Grebes, and an eagle. Not surprisingly much of his later researches was based on observing small groups of tame and semi-tame animals living in his house or laboratory. Those who have known the life and career of Konrad Lorenz and have been drawn to his work and have been influenced by it will find this unusual book most invaluable.

Joseph Needham: 20th Century Renaissance Man. Profile. By Maurice Goldsmith, UNESCO Publishing. 1996.

Joseph Needham was an unusually talented 'polymath' scientist who combined scientific curiosity with Christian humanism. He was gifted with poetic romanticism mingled with political radicalism. In the first half of the 20th century, Noel Joseph Terence Montgomery Needham belonged to the radical intellectual movement and was part of an 'invisible college'.

President and master of Gonville and Caius College, Cambridge, and OM, FRS, and FBA, Needham was the recipient of innumerable national and international honours. It is of historical interest to know that he was also responsible for the inclusion of 'S' for Science in UNESCO.

And at the end of the World War II, when Julian Huxley was invited to organize the UNESCO, he asked Needham to assist him in the gigantic task of planning and executing the first global organization of its kind under the Charter of the United Nations. Needham was the author of many scientific works – books and articles – concerning morphology and biochemistry that created synergism of science and religion, and of political activism with academic social responsibility. In his search for scientific universalism he became the historian of Chinese science and technology. He produced and edited voluminous investigative and interpretative studies of scientific principles belonging to the mysterious land of the Orient.

But Needham was also a man of spiritual commitment who endeavoured to create the Kingdom of God on this Earth and in his entire awakened years (1900–1995) he loved divinity in humankind beyond consideration of nation, race, gender and religion. He was, however, a Christian by faith but his respect for religion was more philosophical and less theological. He was a regular visitor to the Thaxted Church where he often delivered Sermons. Topics of his lecture from the pulpit included Ethics of Economics and Science, Against 'Holy War', Ideas of the 'Just War', Religion and Superstition, and Shintoism, Japanese Confucianism and the Cosmic Christ. He spoke about the 'Place of Women in the Church' long before we learnt about the LIB and political correctness. Needham was also concerned with the eternal struggle of poverty and often spoke about 'Greed and Capitalism'. He spoke about the need to create an 'International Language and Science'. He worked to liberate Christianity from its age-old blind faith and make the Church and Faith the vector of Scientific Knowledge (Truth). But to achieve a modern scientific civilization, Needham recognized social justice as the prime condition and for this he committed himself and his colleagues to social responsibility.

Maurice Goldsmith has described Needham as 'the bridge builder', and truly Jospeh as a scientist observed similarities and dissimilarities and tried to perceive Unity in Diversities. He recognized many interested scientific principles of chemistry and physics in the ancient writings of China. And even if we cannot say why the technological–industrial revolution took place in Europe in the 17th century, there is no scientific reason to believe that any race or people could be devoid of scientific acumen. The historical studies of Chinese science discovered, translated and published by Joseph Needham contributed immensely in creating awareness about the historical contribution to world civilization by China.

In search of scientific universality Needham travelled across the oceans and flew over the fighting forces of East and West, and drudged through the marshes and backwaters of China. He crossed the traditional racial and linguistics borders to befriend with his Chinese colleagues and students; and learned the language of distant people and after the death of his first wife Dorothy, eventually married the Chinese scientist, Dr Lu Gwei-Djen, in 1989, who became Needham's collaborator–editor of the voluminous *History of Chinese Science, Civilization and Society*.

The book provides interesting details of this historic association of the aristocratic-turned Christian socialist scientist and his scientific collaborative work with the Chinese scientist, Gwei-Djen whom Needham came to know for the first time in 1937, when the young Chinese student worked under Dr (Mrs) Dorothy Needham. In the pursuit of science, the three were united as in a common cause. The three were attracted to each other with scientific-spiritual devotion without causing acrimonous damage to each other or to scientific research. Bound by love and respect for each other they proved the model of social harmony. Joseph had remained married to Dorothy for sixty-three years (1924–87), but his second wife died within two years of their marriage.

The book under review describes the foundational influence of Joseph's bourgeois class-conscious English father who was a medicalman by profession. During his younger years, Joseph often attended surgical operation theatre where the senior Needham was an anaesthetist at large military hospitals in London. But surgery held no lasting intellectual interest for Joseph Needham. The author describes his father's influence in some detail but in this age of politically correctness he has ignored the role of his mother. In fact the two main female characters – Needham's mother and his first wife – receive no due consideration in this otherwise extremely interesting and informative study.

This Profile of Needham volume contains a chapter entitled 'Egg and Embryo' in which the author discusses Needham's scientific contribution to pure research in early embryology. In the 1930s, he was seriously involved in developing the technique of embryological micro-operations in the laboratory of Albert Brachet in Brussels. Along with Waddington and his first wife Dorothy, he worked at the Institute of Otto Mangold in Berlin, and the research done during this period was from a theoretical point of view of historical significance for regions of biology even outside embryology, wherever stimulus–response reactions were concerned.

In *Biochemistry and Morphogenesis*, (published in 1942) Needham, Waddington and others explained that a non-living substance can act as an organizer for the embryonic differentiation of a nervous system. Needham in the study claimed that a piece of boiled mouse heart placed among the living cells of a human embryo induced the formation of a secondary or 'extra' brain. This was evidently of philosophical significance, as it demonstrated that there was a physico-chemical explanation for what had been for centuries believed to be the work of an all-knowing Divinity. (page 40).

Needham's associations with eminent Church leaders influenced him in his scientific-philosophical orientation, and his research findings made him realize that while natural sciences themselves were wonderful achievement of human mind, study of the past achievements of ancient civilizations is also of significance for history of science developed through the ages, and even if from small beginnings the contribution of the ancient people to science is not of less importance.

Julian Huxley commenting on Needham's embryonic research stated that this marks another milestone on the road that biology was taking in its transformation from a statistic to a dynamic science. 'Biologists are under a very real debt to Dr Needham for his wide reading, his critical and constructive facility, and his patient industry which has issued in his fine work'. (*Nature*, 6 February 1932, quoted by Goldsmith, page 39).

The author of this Profile of the 20th Century Renaissance Man, is the master craftman of the scientific Profile of another Renaissance Man – J. D. Bernal. But, then, Maurice Goldsmith himself is a Renaissance Man who at the end of World War-II poineered the study of Science and Public Policies, and introduced the concepts of Popularization of Science and the Science Critics. Closely involved in the development of UNESCO, Goldsmith was appropriately equipped to prepare this Profile of Needham which reads like a poet even though it is full of information of academic interest and historical importance. Needham's China visit in search of scientific classics provides fascinating reading, but more significant are the details of his journey through the backward countryside of China, and his meetings with his Chinese hosts who were exemplary of cooperation with scientific information and warm oriental hospitality.

Maurice Goldsmith's treatment of his Needham Profile is unusually distinct as it is attractively unconventional. The volume opens with an address to Joseph Needham from the author. But it has to end in Obituary to Needham, in P.S.:

> 'Since I wrote the above, I have experienced the sadness of your death on the evening of Friday, 24 March 1995. What has intrigued me is the extensive space which the broadsheet dailies, in particular, have devoted to your obituary...'.

The *Profile* of Joseph Needham is a masterpiece work on a life of the colossal man of science and philosophy in whom were united conflicting forces of Faith and Reason, and whose life offered synergism of knowledge and action. He commanded love and affection and high honour of the academic establishment.

Even though to avoid confrontation with conservative establishment of the Royal Society, Needham used a pseudoname when writing radical political articles, his contribution to contemporary critical science movements has been most appropriately placed in historical perspective by Maurice Goldsmith. The author deserves felicitations for this valuable gift to general readers and to the academic and scientific community at large.

EKLAVYA

INSTITUTE FOR EDUCATIONAL RESEARCH AND INNOVATIVE ACTION

requires

Eklavya is an NGO based in Madhya Pradesh. For the last 14 years, we have been working in rural and urban schools developing innovative curricula and books, training teachers, organising research and studies etc. through field based interaction with the state education system, teachers and children.

We publish magazines for children (Chakmak), for teachers (Sandarbh) and a weekly science and technology feature service for news papers (Srote) in Hindi. We also bring out publications on teaching & learning, health and development issues.

We are seeking to expand our team, and thus invite fresh post-graduates, research students or senior associates to join us.

We are looking for persons with:

1. atleast a postgraduate background in Sciences/Social-Sciences/Linguistics/Mathematics/Education and interest in innovative teaching-learning, field based action research & study, writing etc. *or*
2. background and interest in editing/designing-illustrating/promoting circulation of publications.

We are looking for long-term associates but those interested in short term assignments may also get in touch.

Salaries/emoluments can be mutually decided upon in the context of abilities, experience etc. *Interested may write with full details to*

Centre-in-Charge, Eklavya, E-1/25, Arera Colony, Bhopal-462 016

Any published/unpublished work of yours may also be sent.
Your responses should reach us within 15 days.

For further enquiry: Bhopal: 563380 (10 AM - 5 PM), Delhi: 2280870 (9PM - 10PM), Udaipur: 560615 (8PM - 9PM), Bombay: 5783323 (8PM - 9PM)

MEETINGS/SYMPOSIA/SEMINARS

STORMCUP '97 (Short Training on Research in Marine Cyanobacterial utilization Programme – 1997)

Date: 10–21 February 1997
Place: Tiruchirapalli

The training provides hands on experience on various techniques using different instruments such as LS Counter, GC, HPLC, Electrophoresis, Photomicrography and ELISA. Lectures and field trip to Gulf of Mannar area for field experiments and collection are also arranged.

Contact:
Dr G. Subramanian, Director
National Facility for Marine Cyanobacteria
Bharathidasan University
Tiruchirapalli 620 024
Phone: 0431–660352
Fax: 0431–660384
E-mail: nfmc@bdu.rect.ernet.in.

A Short Term Course on Soft Condensed Matter

Date: 10–15 March 1997
Place: Vadodara

The course will consist of series of lectures with a few tutorials, practicals and will cover the following topics: Surfactants and micro emulsions, Polymers, Colloids and biocolloids, Ferrofluids, Surfaces and interfaces. Experimental methods include: Microscopic techniques (rheology, conductivity, etc.), Scattering techniques (SANS, SAXS, Light scattering), Electron microscopy, Relaxation techniques (NMR, ESR, etc.), Computer simulation. Interested Ph D students and young researchers may apply.

INDIAN ASSOCIATION FOR THE CULTIVATION OF SCIENCE
JADAVPUR, CALCUTTA 700 032

IACS/ADVT/P/4/96

Indian Association for the Cultivation of Science is looking for creative scientists for appointment at the level of:

(1) **Reader** (one post) in the Polymer Science Unit in the scale of Rs 3700–125–4950–150–5700.

(2) **Lecturer** (one post) in the Spectroscopy Department in the scale of Rs 2200–75–2800–EB–100–4000.

(3) **Lecturers** (two posts) in the Solid State Physics Department (in the above scale). Persons having good academic record and capable of initiating and guiding research in the frontier areas of

- (i) Polymer Science
- (ii) Experimental or Theoretical Spectroscopy
- (iii) Experimental Solid State Physics, respectively.

N. B.: One post of Lecturer in Solid State Physics Department is reserved for SC.

Applicants are requested to send their Bio-data along with list of publications, names of referees, expected minimum salary, etc. (six copies each) to the Registrar, Indian Association for the Cultivation of Science, Jadavpur, Calcutta 700 032 before 7th February 1997.

Permission of the present employers of the applicants, wherever necessary, should be furnished. The appointment may not be confined to applicants only.

The posts carry allowances as are admissible to the Central Government Employees stationed at Calcutta. The total emoluments at the initial of the Scale will be Rs 9943 and Rs 6888 for Reader and Lecturer respectively.

(P. C. GHOSH)

COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH
(CSIR), NEW DELHI, INDIA

ADVERTISEMENT NO. 15/96

Position: Director, National Physical Laboratory (NPL), New Delhi.

CSIR, the premier agency established by the Govt of India to undertake scientific and industrial research in the country, is looking for suitable scientist/technologist for the post of Director for its National Physical Laboratory (NPL), New Delhi. NPL, Delhi is a multidisciplinary laboratory and is devoted to carrying out R&D work to advance the frontiers of knowledge in various areas of Physics and applying the knowledge for the technological advancement of the country; to establish, maintain and improve national standards of measurements and to realize the 'Units' based on International System; to assist industries, national and other agencies by offering consultancy services for precision measurements, calibration, development of devices, processes, and solving other allied problems related to Physics. The major R&D programmes of NPL are (i) measurements, standards and calibration; (ii) material characterization; (iii) materials development including carbon–carbon composites, piezoelectric ceramics and ceramic–polymer composite materials, thin film optical coatings and systems, opto-electronic materials and devices, etc., (iv) radio and atmospheric sciences; (v) cryogenics and super-conductivity, etc. The Laboratory offers consultancy services to industry, R&D units, academic institutions and government agencies in the areas of its specialization.

The post carries the pay scale of Rs 5900–200–7300 plus allowances as admissible to Council officials. The appointment to the post will be on contract for a period of six years or till superannuation, whichever is earlier.

For further details, please contact the Director-General, CSIR, Rafi Marg, New Delhi 110 001 (India), (Fax, 3710618; Telex, 031–65202 CSIRIN, 031–66147 CSIRIN; Gram, CONSEARCH, New Delhi).

Interested candidates may send their complete biodata by **25 February 1997** to the Director-General, CSIR, Rafi Marg, New Delhi 110 001.

COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH
(CSIR), NEW DELHI, INDIA

ADVERTISEMENT NO. 16/96

Position: Director, Regional Research Laboratory, Jorhat.

CSIR, the premier agency established by the Govt of India to undertake scientific and industrial research in the country, is looking for suitable scientist/technologist for the post of Director for its Regional Research Laboratory (RRL), Jorhat. The Laboratory is devoted to developing indigenous technologies based on the natural resources of the North-Eastern region and to help in the economic development and industrialization of the North-Eastern region in particular and the country in general. The major R&D programmes of the Laboratory relate to development of oil-field chemicals, agrochemicals, agrotechnologies for aromatic and medicinal plants, drugs and drug intermediates, inorganic chemicals, speciality papers and boards and building materials. In addition, basic research in the areas of Organic Chemistry and Bio-chemistry and Geosciences is also carried out. The Laboratory has one branch Laboratory at Itanagar and field stations in Mokok Chung (Nagaland) and Imphal (Manipur).

The post carries the pay scale of Rs 5900–200–7300 plus allowances as admissible to Central Govt officials. The appointment to the post will be on contract for a period of six years or superannuation, whichever is earlier.

For further details, please contact the Director-General, CSIR, Rafi Marg, New Delhi 110 001 (Fax, 3710618; Telex, 031–65202 CSIR IN, 031–66147 CSIR IN; Gram, CONSEARCH, New Delhi).

Interested candidates may send their complete biodata by **31 January 1997** to the Director-General, CSIR, Rafi Marg, New Delhi 110 001.

WADIA INSTITUTE OF HIMALAYAN GEOLOGY

33, General Mahadeo Singh Road
DEHRA DUN 248 001

Contact Programme on Field Studies of Deformation Tectonics for Young Scientists

Department of Science & Technology, Govt of India has been organizing Contact Programme for Young Scientists over the past several years, with the idea to bring young scientists in contact with eminent scientists in relevant fields, train them in frontline areas, and expose them to major national laboratories and field studies. The next programme in Earth Sciences is planned at Wadia Institute of Himalayan Geology, Dehra Dun from 21 March 1997 to 30 April 1997. The planned programme will focus on field studies of structure metamorphism and neotectonics. Applications for participation in the Programme are invited from candidates who have just completed M Sc (Geology) or who have just started their M Phil/Ph D (Geology). The selected candidates will be paid second class train fare and reservation charges from their place of residence to Dehra Dun and back.

Apply on a plain paper affixing a recent passport size photograph and mentioning the following:

1. Name
2. Date of birth
3. Academic record (starting from Inter/HSC) with year, Percentage of marks obtained, Board/University
4. Present status
5. Any other matter in support of your candidature.

The applications addressed to Dr M. I. Bhat, Wadia Institute of Himalayan Geology, Dehra Dun must reach on or before 31 January 1997.

Nominations are invited for

WINTER SCHOOL ON 'ATOMIC FORCE MICROSCOPY'

Sponsored by
Department of Science & Technology
Govt of India, New Delhi
Under Science & Engineering Research Council Scheme for Young Scientists (SERCYS)

Objective : To expose younger scientists through lectures and demonstrations with latest techniques of force microscopy for imaging of technological/biological surfaces

Time Schedule : 13 February 1997 to 18 February 1997

Participants : A maximum of twenty (20) participants selected out of the nominated candidates from various National Labs/Universities, IITs, RSICs, etc.

Organizing Institute : Central Scientific Instruments Organization, Chandigarh

Venue : Central Scientific Instruments Organization, Sector 30, Chandigarh 160 020

Eligibility

Age : Less than 35 years

Academic Qualifications : Minimum M Sc/M Tech (Please attach a copy of the Biodata)

Nature of work/job : Engaged in R&D/characterization of technological/biological surfaces. (one page write-up concerning nature of work being done by the participants should accompany the nomination)

Assistance from Organizer/ Sponsors : Travel charges as per DST rules will be reimbursed.
Free boarding/lodging

Last date for receiving the nominations : 25 January 1997

Contact/correspondence address:

Dr S. S. Wadhwa
Head, Micropositioning Systems Division,
Central Scientific Instruments Organization,
Sector 30, Chandigarh 160 020
Phone: 0172–657449; Fax: 0172–657082/657267.

MINISTRY OF SCIENCE AND TECHNOLOGY
DEPARTMENT OF SCIENCE AND TECHNOLOGY

JSPS POSTDOCTORAL FELLOWSHIPS: 1997–98

Department of Science and Technology (DST) invites applications from promising and qualified researchers for Postdoctoral Fellowships to Japan for 1997–98 offered by the Japan Society for the Promotion of Science (JSPS) under its JSPS Postdoctoral Fellowships for Foreign Researchers Programme. There are five fellowships to be nominated by DST under the framework of India–Japan Cooperative Science Programme (IJCSP).

Priority areas in which applications are invited

1. Molecular Structure, Spectroscopy & Dynamics
2. New Materials
3. Manufacturing Sciences
4. Modern Biology & Biotechnology, and
5. Astronomy & Astrophysics.

Eligibility

Applicant should:

1. be a citizen of India;
2. be an affiliate of a recognized scientific institution in India including researchers like CSIR, UGC JRFs, SRFs and RAs;
3. hold a doctorate degree when the fellowship goes into effect, which must have been received within six years prior to April 1, 1997;
4. have arranged in advance his/her research plans with his/her Japanese host researcher; and
5. be able to forward the application through proper channel of the parent institution.

Age: Preferably below 45 years.

Duration and commencement of Fellowship

1. Fellowships are awarded for a period of 24 months (if one does not require 24 months to complete the research in Japan, one may propose a shorter fellowship tenure of at least 12 months);
2. Each Fellowship must begin between April 1, 1997 and March 31, 1998.

Host research institutions in Japan

Fellows can conduct their research in the following Japanese institutions:

1. Universities;
2. Inter-university research institutes;
3. Research institutes/scientific research corporations under the jurisdiction of the ministry of Education, Science, Sports and Culture (the Monbusho).

Terms of awards

JSPS provides each Fellow with the following financial support:

1. Round-trip air ticket for the Fellow only;
2. Monthly stipend of Y270,000;
3. Settling-in allowance of Y200,000;
4. Monthly housing allowance not exceeding Y100,000;
5. Monthly family allowance of Y50,000 if accompanied by dependents;
6. Accident and sickness insurance coverage for the Fellow only.

In addition, application may also be made for the Monbusho's Grant-in-Aid for JSPS Fellows (Tokubestu Kenkyuin Shorei-hi) of up to a maximum of Y1,500,000 per year to cover cooperative research expenses such as for equipment, materials, supplies and domestic travel. Grant applications must be prepared by your host researcher and submitted through your host institution.

Application procedure

The Application Forms can be requested from the Programme Office, India–Japan Cooperative Science Programme (IJCSP), International Division, Department of Science & Technology, Technology Bhavan, New Mehrauli Road, New Delhi 110 016. Request for application should be received **latest by February 15, 1997 along with a self-addressed unstamped envelope (12 cm × 27 cm) entitled 'JSPS PD Fellowship FY 1997'.**

The duly filled in application form should be forwarded through proper channel **latest by March 15, 1997.**

We'll help you get there

If you're selling science books/journals or laboratory products, or wish to recruit scientists in your establishment, then

you're sure to benefit by advertising here.

Because *Current Science* reaches nearly every university, scientific institution and industrial R&D unit in India. What's more, it's read by hundreds of individual subscribers—students, doctoral scientists and professionals in virtually every field of scientific activity in India.

Current Science has the largest circulation among scientific journals in India.

And to give you more impact, we're now bigger, and better.

DEPARTMENT OF SCIENCE & TECHNOLOGY

Programme on Nonlinear Phenomena, Complex Matter and Biologically Inspired Physics

The importance of nonlinear science, soft condensed matter (such as colloids, powders, polymers and membranes) and biologically inspired physics has emerged very clearly in recent years. In view of this and given the large mutual overlaps of these disciplines as well as their interdisciplinary nature, the DST has considered it fit to constitute a separate Programme Advisory Committee (PAC) specifically to foster research in these areas. Suitable project proposals are invited in the above general fields.

Research proposals should pay particular attention to the development and application of ideas and techniques that cut across disciplines and/or seek to elucidate and provide insight into the general paradigms of complexity and nonlinearity.

Proposals that come under this general purview include:

Dynamical phenomena far from equilibrium, driven systems, chaos, especially spatiotemporal. This encompasses both model systems such as sandpiles and driven lattice gases as well as 'real' examples such as colloids in shear flow and sedimentation, turbulence, kinetics of phase ordering, granular matter (powders), earthquakes, pattern formation, etc.

Physics of soft condensed matter. Membranes (biological and model), Langmuir monolayers and Langmuir–Blodgett films, micelles, vesicles, lamellar structures, microemulsions, emulsions, foams, and other structures in surfactant solutions: liquid crystals, both thermotropic and lyotropic, polymer solutions, gels, and melts: colloidal suspensions, including ferrofluids, electro-rheological fluids, etc.

Biologically inspired physics. Models in evolutionary biology and population genetics, evolution of complexity, neural networks, optimization, protein folding, motor proteins and molecular ratchets, etc.

Qualified researchers interested in submitting project proposals to be considered for funding may write to the following address for further details:

COVER. The migratory slug-shaped 'embryonic' stage in the life cycle of the social amoeba *Dictyostelium discoideum.* The amoebae making up the slug in the top panel were stained with neutral red, a dye specific for pre-stalk cells. The slug in the lower panel consists of amoebae transformed with the *E. coli* beta-galactosidase gene under the control of a pre-stalk-specific promoter. Both slugs are about 1 mm long. The problem addressed in the paper by Atzmony *et al.* (see page 142) is: why do some ameobae adopt the apparently altruistic pre-stalk pathway? (Pictures: courtesy M. Azhar)

In this issue

Fullerenes

There have been few discoveries in recent times that have had as much of an impact on chemistry as the discovery of the fullerenes. Ever since C_{60}, buckminsterfullerene (named after the father of the geodesic dome, Buckminster Fuller) was conveniently synthesized, by laser ablation of graphite, the literature of chemistry has been flooded with innumerable investigations of new forms of carbon. The inevitable happened in 1996, when the impact of the fullerenes was finally felt in Stockholm with the award of the Nobel Prize in chemistry to Kroto, Smalley and Curl, the three original discoverers of C_{60}. Pradeep (**page 124**) presents an overview of recent research on these new carbon forms, which have stimulated thousands of chemists all over the world. Despite much initial promise in diverse areas ranging from superconductivity to near pharmaceuticals, the fullerenes are primarily still a laboratory curiosity.

In retrospect, the surge of interest in the fullerenes was really fuelled by the remarkable beauty and simplicity of the C_{60} structure and the realization that there must be a treasure trove of all carbon molecules to be discovered. The idea that there could be several new carbon allotropes led to a 'gold rush' resulting in an amazing flood of publications.

The fullerenes brought to chemistry the same frenzied race for new discoveries that was witnessed in physics, following the discovery of high T_c superconducting materials. To the historians of science, superconductivity and fullerenes will provide fascinating case studies, when an analysis is conducted of the state of chemistry and physics in the final decades of the twentieth century.

Suicide in amoebae – altruism or selfishness?

When a honeybee colony is disturbed, worker bees will unhesitatingly attack the marauder with a painful sting, notwithstanding the fact that for the bee, to sting means to commit suicide. The sting of the honeybee is armed with barbs pointing inwards so that when firmly lodged into the skin of the victim, it cannot be withdrawn. When the bee flies away, its abdomen will rupture and the sting, the poison gland and a portion of the bee's intestines will be left behind. This ensures that although the bee dies in a few minutes, the almost invisible poison gland will keep pumping venom into the victim's body for considerably longer than the bee might have been able to do. When free-living amoebae of the cellular slime mold *Dictyostelium discoideum* exhaust their local food supply, they will come together and form a multicellular slug which will differentiate into a stalk made of dead cells and a spore filled with live cells. The stalk helps the spore rise above the ground and thus increase its chances of being carried away to a new, hopefully nutrient-rich habitat. None of the amoebae are individually up to this task of dispersal but by the sacrifice of some of them, others have gained a finite chance of survival. Despite the extremely different proximate mechanisms by which such altruistic behaviour may be achieved in the bees and the amoebae, there is an underlying similarity in the evolutionary consequences of their behaviour – some individuals behave in a manner that increases the Darwanian fitness of others while decreasing their own fitness.

Providing a common interpretation for the behaviour of amoebae and bees is a triumph of modern evolutionary biology but the mechanism by which such behaviours are shaped by natural selection remains a matter of much debate. Prior to the 1960s, the standard explanation was that any behaviour that is good for the group as a whole would be favoured by natural selection even if it is bad for the individual performing it, because natural selection was thought to always act at the level of the group and override the interests of the individual for the sake of the group. Although this interpretation found much favour in Victorian England, the recognition of the susceptibility of such group selection to invasion by cheaters led to the development of the theory of kin selection, a theory which argued that altruism towards genetic relatives is more likely to evolve as the sacrifice by the altruist can be compensated by the reproductive success of the recipient. Amotz Zahavi, who sees in the arguments of kin selection, the same instability due to invasion by cheaters that others see in group selection, has achieved the status of a lone crusader for the lost cause of good old individual selection. According to Zahavi, there is really no altruism – all apparently altruistic acts are a veiled form of selfishness as individuals attempt to do the best they can under the circumstances they find themselves in. In this crusade, Zahavi is literally moving from place to place and from organism to organism, enlisting the cooperation (altruism?) of the not too skeptical, to push individual selection arguments to their logical conclusion.

On **page 142** of this issue we see the result of this stop-over at Bangalore and at the cellular slime molds, as Daniella Atzmony, Amotz Zahavi and Vidyanand Nanjundiah attempt to explain the apparently altruistic behaviour of the amoebae on the basis of individual selection. According to their bold hypothesis, high quality amoebae produce a poison and coerce low quality amoebae to accept an altruistic role, the alternative for the latter being even more certain death. Whether or not individual selection will eventually be adjudged as a satisfactory explanation for altruism in the slime molds and other organisms, an honest attempt to examine the possible role of individual selection is extremely valuable, and will prove to have been so even if the final answer is in the negative. And the biochemical implications of the concepts they introduce – quality, poison and coercion – are bound to provide new directions for more empirically minded investigators.

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final version in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred.) A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts, subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.).

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

EDITORIAL

Reaching out to Industry

The wide and alert readership of *Current Science* and the support of a few government departments and agencies, have contributed in making *Current Science* an active and speedy medium of communication among scientists in India. *Current Science* is also shaping to be an important forum for information and debate on policy matters relating to science and technology (S&T). In the first three decades of its existence, this journal published 5 to 6 pages of news, containing accounts of new processes developed by industries, patents, articles on technology, engineering development and applied science. It is now all the more necessary to recapture that vision with greater vigour. There is a general belief in the Nehruvian statement that the future belongs to those who make friends with science. It is also being increasingly realized that the future of science in India will be healthier and brighter if the S&T community interacts more closely with users and industries.

We need not repeat here the successes of industry–science interactions, which have made many Western countries (and companies) great economic powers. Closer to home Japan and several newly industrializing countries have demonstrated the role of this nexus. In India too, we are not without several such examples although missed opportunities far outnumber our success stories. Clearly, the time is ripe to jettison our inhibitions and approach the issue of industry–academia interactions with fresh vigour. *Current Science* can provide a valuable forum for developing a new synergism between academic science and technological innovation. This journal would like to invite participation from a wide cross-section of R&D laboratories in promoting both basic and applied science. We look forward to interactions with scientists and technologists in private laboratories, as readers, authors, referees and critics.

Although the columns of this journal have largely catered to academic researchers in India, over the past few years the scope and reach of the journal has been considerably enhanced. In keeping with the times this seems an appropriate moment to reach out to industry. Science in India has rarely been driven by technological compulsions, with research often remaining an esoteric activity. However, with imagination and drive there is every likelihood that a new and effective partnership can be forged between industry and academia, which will eventually enrich the Indian scientific scene.

Undermanaging health care: Lessons of the plague

Current Science should be congratulated for publishing a special section on the 'Plague epidemic of 1994' (*Curr. Sci.*, 1996, **71**, 781). The report sets at rest once and for all, the controversy regarding the etiology of epidemics between August and October 1994 in the Beed District of Maharashtra and the Surat city of the state of Gujarat. The Technical Advisory Committee (TAC) on plague deserves our gratitude for completing so thoroughly the task assigned to it.

The report, however, highlights some glaring deficiences not only in our health care delivery and surveillance systems, but also in our administrative machinery. Unfortunately the scientific community does not emerge out in flying colours either.

TAC was able to bring together the scientific expertise – from epidemiology to molecular biology, existing within the country, to unravel the total story of the epidemic. The unedifying controversy amongst the various groups of 'investigators' at the peak of the epidemic, not only created confusion amongst the people but also discredited the scientific community nationally and internationally. Notwithstanding Ramalingaswami's words of praise for the Government in dealing with the situation, it is obvious that the existing scientific capabilities were neither mobilized nor co-ordinated with any sense of emergency or responsibility. The whole episode gives credence to the adage, 'There are no underdeveloped countries, only undermanaged ones.'

To start with, I must give all credit to the multiple purpose worker who initially suspected the diagnosis and alerted the medical officer at the Primary Health Centre. This is even more creditable considering that the disease was considered to have disappeared from the country – no proven cases having been reported since 1967. The blame for creating confusion must, therefore, rest with so-called 'specialists' and health administrators. It is unfortunate that those with real expertise, and not just 'assumed competence', were not involved at the very outset. As a matter of fact, it is regrettable that at least some of the competent persons who in the very beginning offered their services voluntarily, were denied access to the available pathological material and even ordered to surrender whatever they had. I make this statement with full sense of responsibility, having personally talked to the then Director General, Health Services, Government of India on this issue at that time. His assurance to remedy the situation obviously did not materialize. There was inadequate and unsatisfactory collection of specimens throughout the fortunately short-lived epidemic. This assumption is confirmed by the TAC report (*Curr. Sci.*, 1996, **71**, 783), 'The serological investigations in Beed and Surat outbreaks were handicapped by lack of availability of paired serums at appropriate intervals. Acute phase sera were generally not available.' In addition, one wonders as to who was at fault for not obtaining aspirates from bubos for establishing the diagnosis of the Beed outbreak. This is not the first time that such a glaring lapse has occurred. Some years ago during an outbreak of gastroenteritis in Delhi, there was enough confusion about whether it was an epidemic of cholera. Enquiries soon after from the then Director General, Indian Council of Medical Research whether efforts had been made to collect and preserve appropriate blood and stool specimens for detailed studies failed to elicit the necessary information. Obviously these were not.

The report also highlights the fact that the agency/agencies primarily responsible for surveillance and investigations of such epidemics are either ill-equipped or ill-prepared to meet the challenges of the occasion. The Defence Research and Development Establishment (DRDE) which ultimately undertook the task of isolation and characterization of *Y. pestis* from rather unsatisfactory stored cultures, needs to be congratulated. However, one presumes that the agency primarily responsible for it was unable to discharge the responsibility satisfactorily! It is regrettable that scientists at NICD – the National Centre for Plague – are in need of strengthening 'in its microbiological and molecular genetic capabilities' (page 786). Obviously this weakness was not recognized early enough to mobilize from the beginning scientists at AIIMS, PGI, DRDE, CCMB, who finally were able to establish the cause of the epidemic utilizing the latest diagnostic techniques. I am tempted to quote from the book review on *Plagues. Their Origin, History and Future* in the same issue of *Current Science* (page 807), 'It is one of nature's supreme ironies that, during the unusual juxtaposition of circumstances that leads to an outbreak of plague, all the major participants in the drama are sick. This includes the humans, the rats, the fleas and the very bacteria themselves.' To this may be added the national health administration!

Willis in his book attributes the low mortality associated with the 1994 plague to 'band aids' (antibiotics and insecticides) but cautioned about the need to address the underlying reasons that provoked the epidemic in the first intance. Panda *et al.* who carried out the molecular characterization (see pages 794 –799) observed the unique ribotype of the *Yersinia* from Beed and Surat, quite different from isolates tested from other regions of the world. One wonders if after the completion of its assigned task TAC has been able to create a working group to undertake further studies and ensure continued surveillance.

It is gratifying to note that in April 1996, nearly two years after the event, the Government of India has established a National Apical Advisory Committee (NACC) for National Disease Surveillance and Response System. Obviously believing in the infallibility of our Administrative Services, the Committee is to be headed by the Secretary of Health, GOI and not the Director General of Health Services or an eminent biomedical scientist.

The recent episode of dengue fever, with a high incidence of haemorrhagic and shock syndrome cases, predicted by medical scientists in the country well in advance (Lall, R. and Dhanda, V., *Natl. Med. J. India*, 1996, **9**, 20) once again raises serious doubts about the national will to meet the challenges of emerging and reemerging infections notwithstanding the creation of NACC. For successful implementation of the tasks assigned to NACC require the establishment of a network of surveillance centres distributed throughout the country, staffed with properly trained epidemiologists, microbiologists and molecular biologists who unfortunately are in very short supply. In any case it is good that at least the need for such a task force has been realized.

New research board for Navy-oriented ocean sciences

The Defence Research and Development Organization (DRDO) has set up a Naval Research Board, effective September 1996. Modelled after the Aeronautics Research & Development Board (AR&DB), the Naval Research Board (NRB) has been set up to strengthen and deepen the knowledge base applicable to the Indian Navy. The NRB has several new features and flexibilities in concept, funding philosophy and operational latitude, elaborated in the Concept Paper, Charter and Executive and Financial Powers of the NRB. Says the 'Concept Paper' in extract:

'If India is to build up the required sea-denial/sea-control capability foreseeable up to 2010–2015 then it will call for appropriate provisioning of a Navy of approximately twice the present size with new weapon systems, surveillance and EW capabilities in all three dimensions. But doing so by import will present insurmountable difficulties; for: *what is developed abroad will not suit our new requirements; what is suitable will be denied; what is not denied will be un-affordable*. This is the already recognizable triple-trap that the Navy will enter in the early years of 2000+.'

Basic philosophy articulating the NRB

The Naval Research Board (NRB) will focus on the generation or enhancement of the applicable knowledge base leading to the exploitation of the sea for military purposes. 'It is important to recognize that the basic philosophy articulating the NRB is the enhancement and expansion of the applicable knowledge base. It is not the definition or achievement of a future naval operational requirement. The aim is increasing our understanding of a topic area. The NRB's projects will be imagination-driven – not requirements driven.

'The NRB will invite research proposals that focus on substantial phenomena or observations that are not understood, and, that lack of understanding is a serious obstacle to scientific or technological progress.' Elaborating:

- The search is for bright people with novel and/or imaginative approaches. 'If you had all the resources you need to do what you want to do, what would you be doing that you are not doing now.' The unit of funding is the experienced leader–researcher and his small team ~ typically one post-doctoral researcher and two or three doctoral/masters students.
- The criterion for funding is the novelty of approach and the likelihood of high-quality research being performed by the fundee, and his team.
- The likelihood of possible future application is NOT a criterion for making a choice between alternative/competing proposals.
- The primary expected end result of the research is a small group of qualified people whose expertise resulting from the research can be drawn upon to build an exploitable area of technology in the subject/topic area, and;
- The secondary expected end-result of the research is a body of knowledge which establishes (or rationally abandons) a potential application of a new, or inadequately understood, scientific principle.

'The knowledge base generated by the NRB through the above philosophy will be embodied in high-quality technical manpower and in the new techniques and design-tools developed through NRB-funding.'

Functions, powers and budget of NRB

- Support basic research that will generate new knowledge potentially useful to the Navy and to train young minds and hands to generate, use and apply that knowledge creatively to the purposes of the Navy.
- Set the principles and practices governing the relationship of DRDO with the academic world; 'think tanks', and non-profit research institutions in India and abroad as well as research strengths in the laboratories of the other agencies like CSIR.
- Consider, and approve, by peer-evaluation, research proposals submitted to the NRB. This evaluation will be accomplished through specialist panels.
- Set up research panels; set funding patterns and funding methodologies for the research panels of the NRB and approve their respective spending proposals for the year.

- Approve research programmes that overlap, or are not covered by, any research panel.
- Decide on specific research programmes or individual projects whose estimate of expenditure spread over the duration of the programme/project exceeds Rs. 20 lakhs, or involves expenditure on major civil works.

The guidelines define 'major' civil works as works 'which create permanent roofed area on land, or any structures in the sea'.

Collaterally, the NRB will fund the development of any specially-designed sensors, instrumentation, data acquisition and display systems necessary for carrying out the research funded by NRB. The techniques and tools of advanced simulation, and mathematical modelling will be brought to bear upon, and tailored to suit, the research programmes funded by the Board.

- ♦ NRB will also evolve methods to improve cooperation between Indian marine scientists so as to widen and deepen the benefits accruing from national projects through the exchange of expertise and knowledge and better use of facilities.
- ♦ However, NRB will exclude funding of the development of major systems like research sea craft and research submersibles (but will include funding of their use for the purposes of research funded by the NRB).

Of particular note in the 'Concept paper' is the new, innovative NRB programme on training and mobility of researchers, which reads:

'This programme aims to promote, through the training and mobility of researchers, an increase in the quality of human resources available to DRDO and to NRB-funded research programmes as also the enhanced use for these programmes of national ocean-related S&T facilities. The purpose of this programme of the NRB is to stimulate imagination and creativity by encouraging scientists to generate such research proposals to NRB as act as vehicles to serve the objectives below:

- ♦ to allow researchers to travel throughout India encouraging mobility between research-disciplines, between academic institutions, research institutes and R&D divisions of ocean-related industry;
- ♦ to help researchers to use existing large-scale ocean-related research, development, test and evaluation facilities and survey vessels;
- ♦ to improve the scientific and technological cohesion of the Ocean Research Community and increase the general level of scientific excellence in that community;
- ♦ to promote, through networks, the training of young researchers and trans-agency cooperation of scientists on research projects funded by the NRB.

It should be noted that the above are *objectives* of an NRB programme – not merely means.'

NRB programme on the dissemination and exploitation of research results

This NRB programme has as its objective the dissemination and exploitation of the results from scientific research funded by NRB so as to:

- ♦ ensure wide dissemination of research results;
- ♦ catalyse the exploitable areas of research results into innovations.

P. V. Indiresan, former Director, IIT, Chennai and currently Research Professor, Centre for Policy Research, Delhi, has been appointed as the first Chairperson of the NRB.

To fulfil its Charter, the NRB has been clothed with extensive executive and financial powers. Thus, the NRB has been empowered to rapidly identify and deploy on projects/programmes of the NRB 'high-calibre scientific and technical persons, predominantly young, identified both from within the country and abroad, provided they are not persons superannuated from the service of the Government of India or from enterprises. To this end, the NRB is empowered to offer fellowships and adjunct positions flexibly structured so as to maximize the interactions between academia, scientific laboratories or establishments, particularly those of DRDO, as also enterprises in the public and private sectors. These fellowships and adjunct positions may carry emoluments (personal to the individual holding the fellowship or position) not exceeding the maximum salary, and allowances & perquisites, of a head of a scientific agency of the Govt of India.'

Organize and support 'training and hands-on participation, for specified periods, in R&D activities in relevant areas in universities, R&D institutions in India and abroad and companies devoted to R&D'.

Support and fund, 'facility design and construction, including structures in the sea and the hiring of premises and seacraft within the limits of the relevant budget provisions'.

The budget for the NRB is expected to rise from the Rs 1.5 crores available for the second half of the financial year 1996–97, up to about Rs 5 crores per year in a few years.

DRDO sources point out, however, that: 'Money *per se* is unlikely to be a constraint. What is most worrying is the flight of young talent away from research careers in science and engineering. The NRB guidelines permit, in principle, even a 28 year old to receive a handsome fellowship of Rs 15,000 a month (plus accommodation) which figure will go up if and after the Pay Commission proposals are accepted by Government. The moot question is whether we can retain such a person in our national S&T system, even if not in DRDO, after his NRB fellowship terminates.'

Immune recognition

The Nobel prize for the year 1996 in physiology or medicine has been awarded to two immunologists – Peter Doherty and Rolf Zinkernagel for describing the manner in which the virus-infected cells are recognized by the immune system. Their work was published in 1974 from the John Curtin School of Medical Research, Canberra, Australia. Rolf Zinkernagel is now the head of the Institute of Immunology at the University of Zurich, Switzerland while Peter Doherty is an adjunct professor at the University of Tennessee College of Medicine, USA.

Defence reactions against foreign matter and the maintenance of individuality is a trait that has existed from the beginning of evolution and can be observed as incompatibility reactions in hydractinia corals as well as skin graft rejections in annelid worms. Elucidating the defensive role of cell-mediated immune reactions against pathogens began with the discovery by Elie Metchnikoff that macrophages were responsible for protection against foreign bodies in bipinnaria larva of starfish. Ever since, the idea of leukocyte involvement in immunity, has only been confirmed time and time again.

The conceptual need to evoke a distinction between self and non-self became apparent with the proposition of the clonal selection hypothesis by Macfarlane Burnet and David Talmage in 1957. According to this hypothesis, an individual is a mosaic of lymphocyte clones each of which is capable of producing only one type of antibody that is specific to a single antigenic determinant or epitope. Since an individual does not produce immunity against his or her own antigens, clones capable of producing antibodies against antigens normally present within the same individual need to be eliminated in the foetus – a time at which clonal diversification occurs. This is the process of tolerance induction to self molecules and therefore the need to distinguish self from non-self or altered self.

Using inbred strains of mice that they had generated by the 1920s, Ernest Tyzzer and Clarence Little established the presence of genes that controlled tumour rejection and tissue compatibility in general. During his efforts to describe blood groups in these inbred strains, Peter Gorer also observed that a group of genes controlled graft rejection. This gene complex was later termed the Major Histocompatibility Complex (MHC) when a similar set of genes were demonstrated in humans by Jean Dausset. It is now clear that the MHC codes for a set of highly polymorphic antigens known as MHC antigens and that these antigens are unique to each individual member within a species. Expression of these antigens on the tissue cells of one individual causes their recognition by lymphocytes when transplanted to another individual. Such transplants are also known as allografts. Lymphocytes belonging to different individuals recognize the presence of the other's MHC antigen (non-self) and react to it by enhancing their proliferation. It was this ability of lymphocytes to undergo proliferation and blast transformation that was used by Barbara Bain's group as well as Fritz Bach and Kurt Hirschhorn as the principle to develop the Mixed Lymphocyte Reaction (MLR) in 1964. Lymphocytes belonging to one individual termed as the responder are cultured along with irradiated lymphocytes of another termed stimulator cells. Irradiation of the stimulators blocks their proliferation but does not kill them. Hence the proliferating responder population can be followed by measuring the incorporation of tritiated thymidine into its DNA. Such assays along with other antibody-based methods are now used for tissue typing purposes.

The occurrence of cell-mediated cytolysis during graft rejections was also discovered by A. Govaerts at about the same time in 1960 while conducting kidney transplantation experiments in dogs. Lymphocytes from the recipient dog that had already rejected a donor kidney possessed the ability to kill the epithelial cells derived from the donor kidney. This basic observation later led to the perfection of the Cell Mediated Lympholysis (CML) assay.

The CML assay is basically a MLR that is carried out for 5 days. During this culture period, the unirradiated responding lymphocyte population is sensitized to the MHC antigens borne by the stimulator cells. Instead of adding thymidine, the surviving effector (killer) cells are added to lymphocytes or tumour cells matched at the MHC locus with the stimulators. These 'target' cells are labelled with radioactive chromium which will be released when the targets are killed by the activated cells generated during the culture. The use of radioactive chromium enables the quantification of the killing reaction. Thus the assay is based on the recognition of differing MHC antigens on the stimulating population by the responder lymphocytes. However, it soon became clear that CML can occur against many other membrane-bound antigens also.

Rolf Zinkernagel and Peter Doherty showed in their classic paper published in 1974 that Lymphocytic Choriomeningitis Virus (LCMV) would not be recognized by virus-specific cytotoxic T lymphocytes (CTL) if the LCMV-infected target was not matched at the MHC with the CTL effector cell[1,2]. Other target cells expressing MHC molecules different from that of the LCMV-infected stimulator cell were not recognized in spite of being infected with the same virus. In other words, CTL were blind to LCMV if they were not associated with self MHC molecules. This was termed as MHC restriction and was shown by Gene Shearer, Michael Bevan and others to operate for other antigens such as minor histocompatibility antigens, tumour-specific antigens and virus-specific antigens.

We now know that MHC restriction is due to the binding of antigen-derived peptides to the antigen binding cleft formed between the two α helices of the MHC Class I[3,4] or Class II molecule. The recognition of peptide-bound MHC on the surface of an antigen-presenting cell (APC) by the T cell receptor (TCR) makes MHC restriction a universal feature for most T cell interactions. The two subunits of the TCR contain immunoglobulin-like variable and constant domains that fold into a structure resembling the antigen-binding region of antibodies. Recent crystallization studies of the TCR-bound MHC Class I and viral peptide have now confirmed the

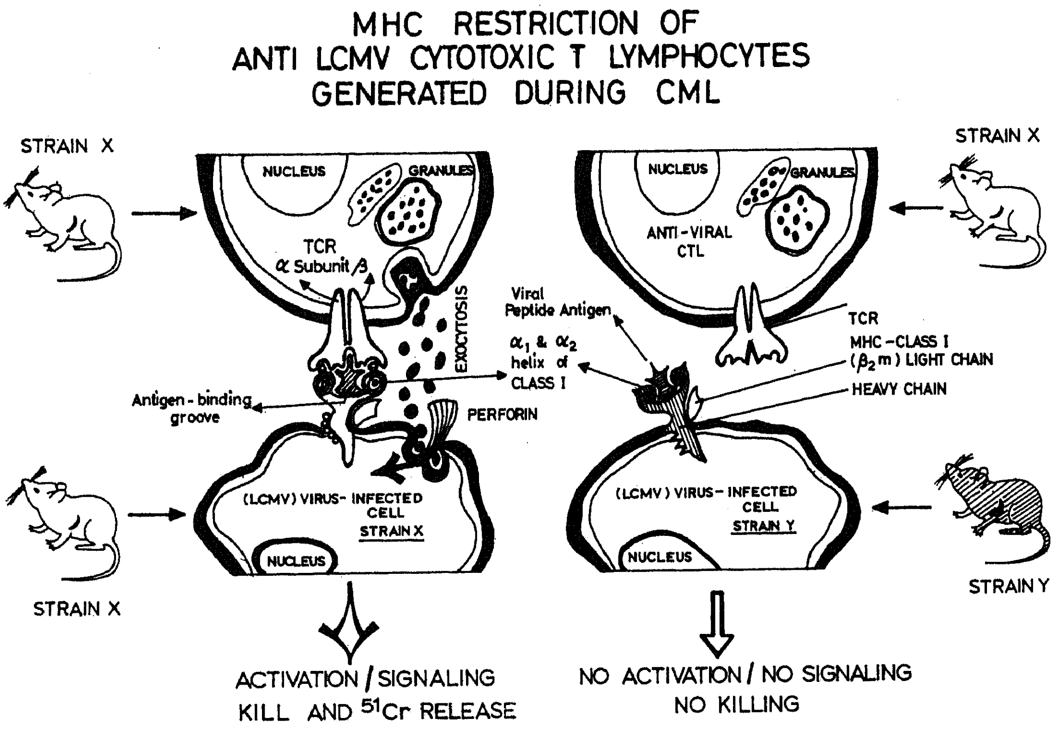

Figure 1.

phenomenon of MHC restriction in three dimensional terms. These papers[5-7] lucidly describe the quaternary structure of the TCR and show that a subunit of the TCR positions itself over the left end of the Class I antigen binding groove while the β subunit covers its right end. The α and β subunits thus make contact with residues in the amino-terminal half and the carboxy-terminal half of the antigenic peptide respectively. Confirmation that antigenic peptide occupies the antigen-binding groove of MHC has come not only from these studies but also from earlier interpretations of the electron density maps that were obtained therefrom[3,4]. The diagonal orientation of the TCR across the antigen-binding groove ensures that the first and second complementarity determining region (CDR) loops of a TCR subunit contact the amino-terminal part of the α_1 helix and the carboxy-terminal part of the α_2 helix of MHC Class I respectively. The TCR β subunit does the same in a complementary fashion, thus enabling the TCR to encompass both MHC and bound peptide in its face.

The affinity of peptide binding to the MHC molecule will be determined by the structural features of the peptide and the MHC allele that it binds to. Different MHC antigens bind different peptides. Thus T cell activation is not only influenced by MHC and peptide but also by the manner in which this complex is recognized by the T cell receptor. It could be speculated that the generation of antigenic peptides by APC could also differ between individuals depending on the manner in which different proteins such as TAP and LMP proteins function during antigen presentation. Therefore the development of most vaccines and therapeutic procedures against infectious as well as autoimmune diseases will be influenced by the discovery of MHC restriction. It is now easy to understand why the award of the Nobel prize to Rolf Zinkernagel and Peter Doherty was well deserved.

Neutrino and muon bursts wiped out dinosaurs

During the long history of evolution of life on Earth, there have been periodic mass extinctions of some of the life forms. Many causes, terrestrial and extra-terrestrial have been advanced for their exit, particularly following the publication of the well-known meteorite impact theory[1] in the eighties. The latest agent of extinction invoked is – cancer-causing mutations triggered by massive bursts of neutrinos released by the dying stars in our galaxy[2], or by energetic muons from neutron stars[3].

Theoretical calculations about the damage that can be caused to living tissues when neutrinos collide with the cell nuclei have shown that they can be quite harmful. Neutrinos normally do not interact with matter but under sudden flood of their emission during stellar collapses, such collisions can take place, and in fact this has been happening within 20 light years of Earth almost every 100 million years. The collision results in recoil of nuclei which damages the DNA, inducing cancer-causing mutations; according to calculations, each recoil may deposit more than a thousand electron volts of energy along a track length of 10 nm, which is a substantial amount – about 12 malignant cells per kilogram of tissue – a damage quite severe considering the fact that dinosaurs are large bodied.

Recently, three astrophysicists from Israel, Arnon Dar, Ari Laor and Nir Shaiv of the Technion in Haifa, have also expressed similar views[3] and feel that mass extinctions during past geological history could have been triggered by the collision of neutron stars. Such collisions could deliver in a single day equivalent of 100,000 years' worth of rays which on hitting upper atmosphere of earth could generate a cascade of highly energetic muons capable of killing organisms directly, apart from destroying ozone layer and making the environment radioactive. However, since muons are stopped by rock and a few tens of meters of water, organisms living below these levels are shielded and survive.

Vagrant North America and its drop out

Ever since Eduard Suess, the Austrian geologist first postulated the giant Gondwanaland, a primeval amalgamation of all the early landmasses, a concept which soon led to the development of the well-known hypothesis of Continental Drifts by Alfred Wegner, geologists have been re-examining and revising the concepts of global palaeogeography. By early sixties, the Wegnerian ideas of continental drifts, which had remained dormant for some decades, were revived with the advent of global plate tectonic theories developed by notable geologists of those times like Hess, Vine and Mathews. According to these theories, continents grew by accretion of crustal fragments and mid-ocean islands; the continents could also break, and segments of such crusts could migrate across oceans. Based on data from stratigraphy, internal structures, fossils, palaeomagnetism, seafloor explorations, mantle dynamics, computer simulations supported by satellite and seismic records, the peregrinations of the continents during the geologic past became clearer, though some of the new thinking about the palaeogeography of the ancient continents are still much debated.

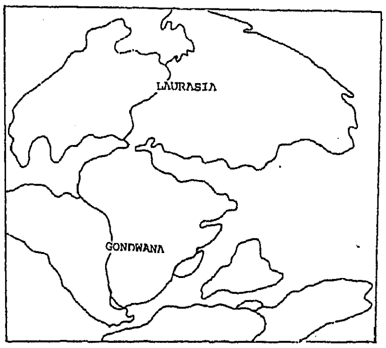

Figure 1. Pangea, 180 million years ago, showing break up into a Northern Laurasia and Southern Gondwana.

Views about the ancient continental dispositions, as a single vast land called 'Pangea', during the Permian times (250 million years ago) and how it split into 'Laurentia' (North America, parts of Europe and a few other continental fragments) and 'Gondwanaland' (Africa, South America, Antartica, Australia, India) during later times are today well known[1] (Figure 1). But the palaeogeography prior to this period, during Palaeozoic and Precambrian times, is difficult to conceive in the absence of ancient ocean floors to provide guidelines. During the last ten years, some attempts at this exercise have yielded a fair picture particularly about the wanderings of the North American continent. This has been deduced from a study of palaeomagnetism in the iron-bearing minerals formed at different periods on this continent. These minerals orient themselves along the magnetic N–S direction (or more precisely, the geomagnetic field) when they crystallize from the magma, and a critical evaluation of their orientation in the rocks formed at different time intervals provides reliable data to infer about the latitudes the continent occupied (wanderings) in the past.

According to a hypothesis[2] presented a few years back called the SWEAT hypothesis (for SW U.S – East Antartica) based on field trips to Antartica by Eldridge M. Moores of the University of California (Davis) and Ian W.D. Dalziel at the University of Texas (Austin), the Shakleton Range of Trans Antartic Mountains expose rocks of similar characters and age (1.8 billion years) as those lying under New Mexico and Arizona or those of Grenville Province on the eastern and southern margins of North America. Hence they believe that these areas must have been juxtaposed at one time during the past eons. This juxtaposition of Laurentia (ancient North America) and East Antartica prior to

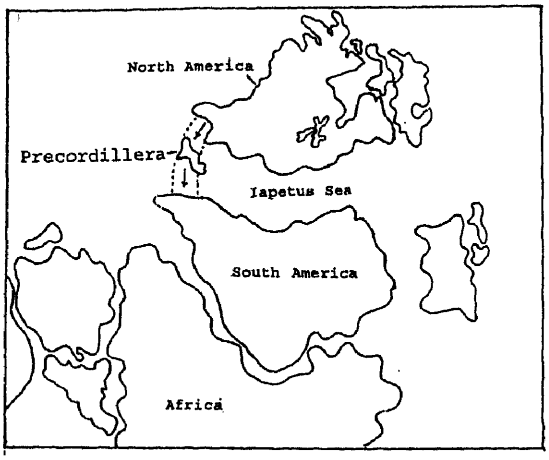

Figure 2. Breakaway microcontinent (Precordillera) adrift in the Iaepetus Sea to dock later with South America (alongside present day Andes).

the formation of Pangea, according to them, could indicate existence of an earlier megacontinent which they called 'Rodinia', a fusion of Antartica, Australia, North America and fragments of South America. The oceans that existed at that time between other continents – India and Africa and Africa and South America were destroyed between 750 and 550 million years and all nucleii of Africa, Australia, Antartica, South America and India amalgamated into the giant 'Gondwanaland'.

They further argue that Laurentia, the ancient North American continent, as per magnetic data, wandered during the late Precambrian and Palaeozoic times around the west coast of South America and collided with it at a place where Andes was pushed up much later and finally, when Pangea was formed, abutted against northwest Africa pushing up the Appalachian mountains in the process. This Laurentia–South America collision during Palaeozoic was also strongly supported by Louis H. Dalla Salda from the Argentinian University of La Plata, on the basis of tectonic and faunal studies in the Andes. Though these inferences about the journeys by the ancient North America were based on computer simulations by Dalziel, he hoped that future discoveries of land fragments, ripped-off continents and accreted to other landmasses, will soon come up in support of his views; and, indeed, they came up soon.

The first such accreted fragment was discovered in the foothills of Andes, as a tract of limestone 100 miles wide and a 1000 miles long, called Precordillera, north of Mendoza in western Argentina. This tract appeared a misfit here and had distinctly different lithology and fossil content with respect to the rest of the surrounding areas. According to Victor Ramos[3] of the University of Buenos Aires, Argentina, the occurrence of distinctly marine trilobites as well as pillow lavas (rocks which form when submarine lava eruptions congeal rapidly) on both sides of the Precordillera would suggest that this segment must have been once surrounded by sea before it became part of South America. He also felt that this piece of land might have broken off the ancient North American east coast (now the southern USA, parts of Texas and Arkansas) some 500 million years ago and drifted to its present position along the Andes mountain range.

The above view recently received strong support from William Thomas of the University of Kentucky and Ricardo Astini of the University of Cordoba, Argentina[4], who found that 'Cambrian fossil fauna of the Precordilerra were identical to those of continental shelf succession of Laurentia and Cambrian succession of Precordillera similar to those of margins of Laurentia'. They also felt that this piece of land must have rifted away from Laurentia (the Ouchita rift), during the Cambrian times and drifted as a micro-continent across the intervening sea (Iapetus Sea, now extinct) as an island before berthing alongside west coast of Gondwana (South America), during the Ordovician, some 80 million years later (Figure 2). Till the time this piece of land was close enough, faunal exchange with mainland Laurentia was taking place; but when the gap widened with time, this segment had its own unique younger fossils which were absent in Laurentia (North America) and later when close to Gondwana (South America), faunal exchanges resumed. They feel that these features strongly support the view that the castaway Laurentian (North American) terrane spent some time as an island before berthing with the west coast of South America; this implies that Laurentia and South America were not in direct contact, a view that questions the direct collision of the two as advanced by Moores, Dalziel and Louis Dalla Salda. There is also a third view[5] that a submarine plateau may have attached the Precordillera to North America. Geologists are now looking for similar castaways – rifted continental segments or terranes – that had accreted to other continents in the globe. Tentatively, they have detected two such possibilities in the rock tract in Piedmont Mountains in North Carolina which appear to be a part of South America as also Oxaco region of southern Mexico.

The 'Vision 2005: Earth Sciences' document of the Department of Science and Technology was recently printed in the pages of this journal (Curr. Sci., 1996, 71, 820–823). An alternative view, espoused by one of India's leading geologists is reproduced below.

– Editors

Priorities in earth science research

B. P. Radhakrishna

'If we want the world to pay greater attention to geology, and if we want decision makers to allocate more resources for geology, then we need to demonstrate the importance of geology in public affairs and we must accept our public obligation to be good citizen geologists.'

E - an - Zen

As the twentieth century is drawing to a close, scientific institutions in the country have taken to the exercise of presenting 'vision papers' outlining the goals of research to be pursued by them. The United Front Government at the Centre too has come out with a Common Minimum Programme (CMP) to be followed during the coming years. It is worthwhile to examine the relevance of these programmes and the role of Earth Science in the present context.

One of the vision documents lists the following areas of opportunities for research in the field of Earth Science: (1) Evolution of the Indian Crust, (2) Himalayan Orogenic Belt, (3) Earthquake Problems, (4) Reconstruction of Palaeoenvironments and (5) Earth Science Application for Societal Needs.

Are these the priority areas of our research? What are we really going to achieve? Do these in any way contribute to the welfare of our people? If such questions are posed, it will be seen that a good part of our research effort is aimless and that we are trying to answer questions which nobody is asking.

The trouble with our research programmes appears to be that our top research personnel occupying senior positions in our universities and research institutions have received training in universities of UK, Europe and America. So trained they cannot but pursue the type of research that is being practised in those countries. Their vision has seldom extended to finding solutions to the problems faced by this country. Science and Technology have yet to become effective tools for national growth and economic development. The time appears ripe for introspection and rethinking.

The glaring fact remains that this country, even after fifty years of independence continues to be one of the poorest nations in the world. It is not as if we are lacking in resources. For its size, India has a variety of mineral and metal resources to satisfy many of its needs. Compared to other parts of the world it receives copious amounts of rainfall. Its soil is fertile. Hill slopes are covered with evergreen forests. The country is populated not by aborigines but by intelligent people with thousands of years of culture behind them. Its human resources are second to none. And yet, in spite of all these plus points, we remain poor. The reasons are not far to seek. It is because we seem to be wasting our time in imitative and aimless research and serious problems facing the country have been largely ignored. Have we tried to identify gaps in our knowledge and pose the right questions? First and foremost there is need for educating the public and those who are occupying seats of power as to what the scope of Earth Science is and what it can do to better our economic well-being.

Energy needs

As a consequence of the big boost given to the growth of the automobile industry, there has been an alarming increase in the number of vehicles and consequently in oil consumption which stands at 65 million tonnes per year. Indigenous production has remained stationary at around 35 million tonnes, necessitating import of the balance quantity of 30 million tonnes per year! This drain is likely to increase in the years to come, causing a big hole in foreign exchange resources amounting to over 7 billion dollars, or nearly 25,000 crore rupees.

Sedimentary basins having a good potential for oil cover an area of 1,400,000 km^2 on land and 720,000 km^2 offshore. This is an indication of the magnitude of the work before earth scientists – geologists and geophysicists alike – in carrying out detailed exploration of these sedimentary basins with a view to identifying favourable structures for test drilling. No concerted effort is yet evident in this direction. We seem to be waiting for others to come and do the job for us. The zeal and enthusiasm which were in evidence at the time of the formation of the Oil and Natural Gas Commission are lacking today. If goals are set and our scientists motivated and encouraged, there is no reason why India should lag behind in attaining self-sufficiency in respect of her oil requirements. One need not always be on the look out for giant fields, the many smaller fields also require attention.

The same lack of will is evident in the development of natural gas resources. Adequate attention is yet to be directed towards wise utilization of the identified reserves. In any agenda for research in the coming years, the identification of fresh resources of hydrocarbons should, therefore, occupy the first place. Geophysicists and geologists have a challenging task before them in these areas alone.

There is quite a bit of loose money in the country as is revealed by the insatiable thirst for possessing gold. Annually not less than 25,000 crores are being diverted in this way for want of better avenues for investment. Government policies and private initiative should aim at providing incentives to wean people away from investing their surplus money in gold and divert it for nation-building activities.

Reprinted from *J. Geol. Soc. India*, 1996, **48**, 493–496; 611–616.

Mineral resources

We do not yet have a comprehensive volume on the Mineral Deposits of India to enthuse our young men about the immense possibilities that exist in the development of our mineral resources. The Mineral Year Book brought out by the Indian Bureau of Mines falls very short of what is actually required. The geological setting of the country holds great promise for a boom, in mineral production and in order to usher in such a boom, regional mapping programmes have to be accelerated in order to stimulate mineral exploration. Proving extension of known ore bodies, identifying new ore zones and discovering new satellite ore bodies are items of research which should be encouraged and adequately funded.

Gold production has remained at a miserably low level. There is no urge or incentive to produce more. Hundreds of promising occurrences which should be humming with activity are left undeveloped, denying large-scale employment opportunities to the rural poor.

Utilization of resources

The practice of exporting large quantities of iron ore, manganese ore, chromite, barite, etc., without any processing to add to their value is still continuing unabated. This will not bring any prosperity to the country and requires to be stopped. The setting up of iron and steel production units is a step in the right direction and these industries have to be helped in obtaining an assured supply of suitable raw materials. This in itself is a major task which could provide unlimited employment opportunities to earth scientists.

Decentralization of powers

The CMP of the Government of India does not make any reference to the development of mineral resources. It, however, recommends devolution of powers to the States. This is a welcome move, as at present all power is centered in Delhi. Decision making is avoided at all levels, making the task of obtaining a mineral concession a most frustrating and exasperating exercise. The spate of applications received as a result of the liberalization policy announced by Government more than two years ago are still lying in cold storage with absolutely no action taken on any of them. There is no reason why State Governments, which are keen on developing the resources of their respective States should not be empowered to decide on the grant of mineral concessions subject to strict observance of rules and regulations in this regard.

Close association with industry essential

Official Survey Organizations, Universities and Research Institutions should forge greater links with industry and not function in isolation. Considerable amounts are being spent by several government organizations on exploration without first identifying the exploiting agency and follow-up action on mining and mineral processing is conspicuous by its absence. There is great apathy both in government and the private industrial sector, towards mining and exploitation of mineral resources. Need-based research should receive greater emphasis and be financially supported. Projects undertaken by research institutes and universities should be oriented towards providing the industry with new and more efficient technologies.

Subsequent exploration and exploitation should be in the hands of a large number of private companies and individuals and not in the hands of governments as at present. Official survey organizations can play an important role providing the industry with detailed geological information, maps, and conceptual models, which will prove helpful in these areas and help the quest for new exploration concepts and in the discovery of new ore bodies. Key centres of research in economic geology should be developed where Government, Universities and Industry shall work in close co-operation. Increasing amounts should be made available for research in this field.

Every project undertaken by the official survey organizations should end with a detailed report, which should be readily available to interested exploratory organizations and persons and not kept in cold storage as at present. Official survey organizations should also provide effective, responsive and efficient customer service. There is no harm in throwing open the country, with adequate safeguards, to international exploration, as all efforts at resource identification and exploitation should be encouraged. It is a never-ending process which, fuelled by its own successes, will gain momentum.

This does not mean that basic research should not be encouraged, but that is best confined to a few specialist groups. Repetitive and imitative research on the same type of problem by different Institutes and University Departments will not produce results commensurate with the time and money spent.

Significant progress possible

That India can make significant contributions in the field of science and technology is borne out by the spectacular results achieved by agricultural scientists in bringing about the green revolution and making the country self-sufficient in its requirements of food grains. Earth scientists too, can make an equally striking contribution if only they go about it in the right way, identifying resources and developing the skills for utilizing them to satisfy the Nation's requirements.

If spectacular progress can be achieved in highly specialized fields like software technology, cold fusion, and adventures in space, there is no reason why India should lag behind in developing her mineral industries and produce real wealth. What is needed is massive co-ordinated research programmes with the provision of adequate financial support unhampered by bureaucratic control. It is not the lack of instruments that is retarding progress but the lack of a will to succeed. Making a start is half the battle won.

Water-related problems

The ugly spectacle of feuds that are raging between States over sharing river waters is before us as a standing warning as to what is in store for us in the near future. Most of the problems that the country is presently facing appear to be the result of mismanagement rather than lack of resources. There is enough water to satisfy our needs but, who can place a limit to human greed?

Our knowledge about the water resources of the country and the extent of their utilization is far from satisfactory: Take the water needs of a city like Bangalore – we have no information on what percentage of population of the city depends on municipal water supply, how many depend on groundwater for their needs and how many live by purchasing water from dealers? State Groundwater Boards do not have correct records of the number of bore-wells that exist and the quantity of water pumped each day. No limit is placed on the exploitation of this essential and precious resource. Every day we hear of large sums being sanctioned for sinking new bore-wells without first considering the effect of large-scale withdrawal on a shrinking resource. An alarming decline in the water table has not in any way dampened the zeal for new wells, and hardly any attention is given to the replenishment of the resource through recharge. Forests which had the effect of arresting rainwater run-off and recharging groundwater reservoirs are being destroyed, leading to floods and severe soil erosion. River channels and surface water reservoirs are getting choked with silt. No effort is made to impound rain water and allow it to percolate down and recharge the groundwater reservoir. The extent of work awaiting the attention of geohydrologists is enormous.

Nature has provided a vast interconnected reservoir of water below ground. Ways of replenishing this reservoir should be our main concern. Attention has to be given to terracing, contour bunding, creation of farm ponds and afforestation of catchment areas. Such practices have the aim of arresting the free flow of rainwater and allowing it to infiltrate below ground and enrich the groundwater reservoir. Scientific knowledge has to be put into practice in demonstration plots and the message of water conservation conveyed to the public. The scope for service in this field is unlimited.

The advent of down-the-hole hammer rigs capable of drilling rapidly, even through hard rock, and the deep-well turbine pumps capable of lifting enormous quantities of water have revolutionized agriculture. They have, at the same time, allowed unlimited withdrawal of groundwater far in excess of annual recharge. Technology, while helping the farmer, has tended to jeopardize and possibly ruin a precious resource through overuse.

Withdrawal of groundwater in excess of the annual recharge should not be permitted under any circumstances. It will lead to a lowering of the water table and result in every other well in the region going dry. This is already happening in many parts of the country and if this practice of unrestricted utilization continues, there will be a water crisis in the not-too-distant future. When that happens, water will not be available even for drinking, let alone for irrigation.

The extent to which surface water and groundwater are increasingly polluted as a result of the use of pesticides and fertilizers is another major problem. Remedial measures to prevent chemical pollution of the precious resource must be taken without delay.

Educating the intelligent farmer, making him understand the problems he has to face and acquaint him with appropriate remedial measures he has to take to protect this resource is the paramount need of the hour.

It is earth scientists who are primarily concerned with the study of all aspects of groundwater – its occurrence, quality, exploitation and conservation. Unfortunately Research Institutes, and University Geology Departments have given a low priority to the study of groundwater-related problems. This is the one field where they can come into close contact with the people and in which, they can, by the application of their scientific knowledge, contribute to public welfare. Earth scientists can have all the job satisfaction they need, when they realize that they are of some service to their fellow men.

Surface water resources

Surface water resources too are not being used wisely. Vast sums of money have been spent in building high dams and storing large quantities of water. In this process, very large expanses of valuable agricultural land have got submerged, causing wholesale displacement of local populations and consequent untold misery. While engineering skill of a high order is evident in the construction of major reservoirs, the same technological skill has not been displayed when it comes to the proper utilization of the stored water. Methods presently adopted for conveying water are the most primitive and wasteful, in no way different from the practices followed thousands of years ago. Irrigation, as a result of such wasteful practices, remains the largest sick industry in India today with hardly any return on the huge capital invested. Major irrigation projects stand as examples of wasteful utilization of a precious resource, with no regulatory structures and measuring devices for supply of water. No value is fixed for the water supplied, resulting in wasteful utilization, far in excess of what is actually required. In this process, fertile land is also getting degraded, waterlogged and saline.

In matters of water conservation much can be learnt from Israel. Water in that arid country is an exceedingly precious commodity calling for maximum conservation. It is conveyed through pipes to prevent loss through seepage and evaporation and meters are installed to regulate supply with no wastage permitted. Sprinkler and drip irrigation are practised on a large scale in order to obtain maximum benefit from the water. We, on the other hand, by continuing obsolete and wasteful practices, are conveying water in open cut trenches using only 30% of the stored water in crop production. In the face of a rapidly growing population and the need for growing more food, we can ill afford such amateurish and unscientific utilization of water.

Water is the most precious of our natural resources and has to be conserved and used with great care. Effecting improvements in our irrigation practices is a realizable goal which has to be implemented without delay. Yields under flood irrigation, as practised in India, are too low, less than one tonne per hectare, while Japan, with controlled irrigation, has been able to produce 5.5 tonnes and in some cases as much as 8 tonnes per hectare. This is an indication of what is possible.

There is, again, a craze for planting water intensive crops like sugarcane. It should be remembered that water required for one hectare of sugarcane crop can irrigate 10 hectares of wheat. Scientific planning is necessary in making use of limited water resources and drawing maximum benefit.

Surface storage even in our largest dams is far from dependable. Dams can at best store one year's supply only and cannot safeguard against years of drought. Greater attention has to be given to groundwater reservoirs as their storage capacity is considerable and they can help tide over years of poor rainfall.

Those who benefit from major irrigation works are the richer and more articulate sections of society. The water need of the large majority of the population, living in regions far away from perennial sources and affected by droughts almost every year, is sadly neglected. No single Research Institute, to my knowledge, has specialized in water resource management and the country may have to pay a heavy penalty for neglecting this most important field of research.

Land use planning

It is estimated that there are 142 million hectares of arable land, of which only 46 million hectares have been brought under agriculture, the rest lying barren. The country cannot afford to allow such vast extents of land to lie barren. Science and technology aided by the intelligent use of modern mechanical devices should bring much of this land lying fallow under the plough. Terracing of land, excavation of contour ditches, erection of bunds, afforestation and all such land-use practices aimed at arresting free surface flow of rain water and making it percolate into the ground are needed.

Private industry and business establishments should take to farming and organize agriculture as an industry. Large investments are needed for developing infrastructure like roads, wells, drip irrigation pipe lines, pump houses, fencing and drainage. Modern technology has to be adopted with a view to seeing that every drop of water is utilized and the precious resources never allowed to run waste. Such development can bring about a major revolution in irrigation through planned groundwater exploitation.

Research on a variety of topics related to use of surface and groundwater can be suggested. Soil geochemistry, soil productivity, estimation of optimum requirement of water for different crops, estimation of evapo-transpiration losses, soil fertility, effect of irrigation on groundwater regime, conjunctive use of surface and groundwater, efficient water management, irrigation water-use efficiency, formulation of irrigation methods aimed at water conservation, salinity, prevention of soil degradation through excess irrigation – all these need expert attention. The problems are complex and require the combined efforts of hydrogeologists, irrigation engineers, and soil scientists. What is more important is that the results of research should be continuously communicated to the farmers, making it easy for them to grasp the details and enabling them to adopt new technology for better water management and improving agricultural efficiency.

Agricultural scientists have shown a better sense of responsibility. Instead of wasting their time in inappropriate research, they have adopted down-to-earth policies and deviced innovative measures to improve the conditions of the farmer. There has been a phenomenal increase in food production and very soon the country may become an important exporter of food grains. The most advanced research is being directed to produce hybrid seeds and step up food production. This is because, the large majority of agricultural scientists are engaged not in aimless academic research but on practical research oriented towards finding solutions to the problems faced by the farmer.

Environmental problems

There are several environmental problems which only geoscientists can solve, for they have the necessary geoscientific knowledge gathered over a period of years. Areas of special interest are: waste disposal, threat of natural hazards like floods, landslides, earthquakes, desertification, coastal erosion, etc.

How to improve the quality of life of our people should be the primary concern of present and future geoscientists. Geology, it should be emphasized, is a social science and not a laboratory oriented discipline. The whole earth is its laboratory and human welfare its goal. Playing down field work and glorifying laboratory-oriented research has been the root cause for the decline in pubic appreciation of the value of geologist's services.

Environmental considerations should not, however, come in the way of progress by putting obstacles in the development of resources aimed at improving the quality of life of the common people. A balance has to be struck between stepping up mineral production and preservation of environmental quality.

Quaternary studies

Processes which have operated on the earth, especially during the last 10,000 years (Holocene), need special study. Information on rates of erosion, sediment transport and accumulation in standing bodies of water, is lacking. Sediment cores from silted-up reservoirs offer the best material for study as they preserve a faithful record of environmental changes.

The Himalayan terrain, which is environmentally fragile, requires special attention on the part of earth scientists. The evidence afforded by river terraces and the distribution of plant and animal life point to uplift of the terrain even after the advent of man. Rivers have changed their courses, transforming fertile lands into deserts and *vice versa*. Deformation as a result of uplift and movement along faults has made the area particularly prone to landslides. Floods are causing enormous havoc almost every year. Earth scientists, through detailed field studies, should be in a position to develop prognostic capability, identify areas prone to natural hazards and forewarn the people. This is another field of research in earth science which should be undertaken on a priority basis.

Study of soils and soil forming processes

India has the largest accumulation of fertile black soils, specially in the States of Maharashtra, Madhya Pradesh, Karnataka and Andhra Pradesh. The role of parent rock and changing climatic conditions in soil formation has not been clearly understood. A clear understanding of processes leading to soil formation, reasons for degradation of soil and scope for regeneration and increasing soil productivity, should form an important branch of earth science research.

More important than dating rocks formed thousands of million years ago is the dating of geologically young materials like soils. Information on the time required for soil formation is lacking at present. New techniques, using isotopes produced by cosmic radiation, being applied elsewhere to solving current problems can also be attempted here for better soil management and conservation.

Palaeontological studies

Palaeontology, the study of ancient forms of life, is at the very core of earth science studies. The main contribution of geology and its greatest triumph has been the decipherment of earth history during the past 600 million years. In spite of this enviable past record, palaeontology is today a neglected field of study.

The zonal classification of strata, using macro and micro fossils, ought to be a continuous process refining the stratigraphic record. Such studies of samples collected from off-shore wells and cores recovered from the ocean bottom and deep drilling projects have great practical importance in the exploration for hydrocarbons. Modern technological aids like electronic imaging system and electronic data bases have greatly enhanced the value of palaeontological studies. Palaeontology combined with seismic stratigraphy can be a powerful tool in providing chronological control. Major global environmental events can be recognized more precisely by the appearance and disappearance of organisms.

Geological Survey Organizations at State level and University Departments teaching earth science should take the initiative in organising natural history museums, with ancient life forms on display, kindling interest in the minds of children and the lay public. The success of *Jurassic Park* and the crowds of visitors attracted to view life-size, models of dinosaurs indicate the extent to which the public can be made to realize the importance of geology in understanding the history of the evolution of the earth and its inhabitants.

The foremost need of the hour is to do everything possible to increase productivity in our agricultural land and in our industrial establishments. The all-pervading bureaucracy should reorient its thinking and develop a helpful, instead of an obstructionist, attitude. The inferiority complex that is apparent in many of our young men should be replaced by confidence in our ability to develop our resources to our advantage.

My main object in drafting these notes is to focus attention on the need for geoscientists to bestir themselves and strive their utmost to increase their knowledge about land, mineral and water resources and be of service to the people. Societal obligations should gain precedence over purely professional recognition. Subsidies are not going to improve the living conditions of the rural poor but will kill all initiative and condemn them to live on perpetual doles. What is needed is employment opportunities and assurances of adequate income. This is possible only through development of land, mineral and water resources on a scientific basis.

The President of the Geological Society of America in his recent Presidential Address posed the question 'If geoscientists went on strike, would anybody notice?' Our geoscientists should likewise ask themselves – 'how relevant is my research to the needs of the country and the betterment of the people?' In the final analysis 'the support of the geologist depends on public appreciation of the value of his services'.

'Do you wish to be a patriot? – then tune yourself in love with your country and the people.' – Swamy Rama Tirtha.

B. P. Radhakrishna is in the Geological Society of India, P.B. 1922, Bangalore 560 019, India.

Academy initiative in university education

The Indian Academy of Sciences, as a part of its initiative in university education, has limited funds available to support:

- Short visits (4–8 weeks) by college/university students and teachers to Academy Fellows for joint work on specific projects.
- Short intensive lecture series by Fellows in colleges and universities.

Proposals are invited by the Education Panel of the Academy (R Narasimha, Chairman) for the above from college and university teachers and students. They should include a brief resume, a one page description of the proposed activity including its duration and tentative dates, and a letter of consent from the concerned Fellow, and should be mailed to: *Executive Secretary, Indian Academy of Sciences, PO Box 8005, C V Raman Avenue, Bangalore 560 080.*

CdS nanocrystallites: An efficient light emitter

When wide band gap semiconductors with appropriate doping are exposed to light with energy larger than the band gap, it may so happen that it emits visible light. In order to qualify as an efficient light-emitting material, a semiconductor must have band gap ~2.0 eV. For many years, wide band gap II–VI compounds, viz. ZnS, ZnSe and CdS have been good candidates for such light-emitting devices under UV and electron beam excitation. In principle, the band gap can be varied by changing the crystalline size. As the crystalline size decreases, the band gap value increases. Thus, for low band gap material, one has to control the crystalline size to obtain the required band gap value.

Efficient light emission has already been reported for Mn^{2+} doped ZnS (ref. 1) nanocrystallites synthesized by polymer caping technique. Essentially, favourable energy levels within the band gap of nanocrystalline ZnS are created by doping for efficient luminescence transfer. It emits yellow light similar to the luminescence from bulk doped ZnS. What changes is the efficiency of the process. The efficiency changes from 0.3% in bulk to 18% in nanocrystallites, leading to a tremendous improvement in the brightness of emitted light. Because of the small size, the intensity of emitted light becomes more.

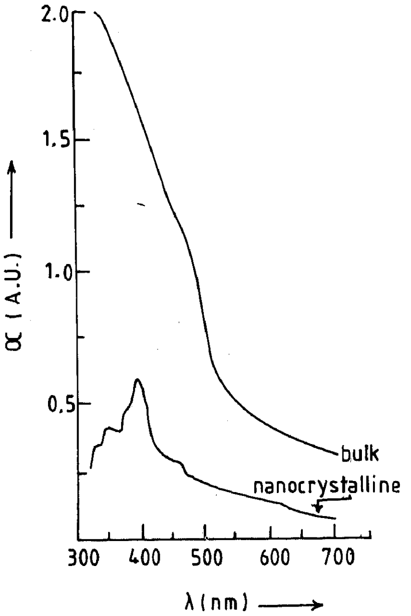

Figure 1. Room temperature optical absorption spectra of CdS semiconductor of different crystalline size.

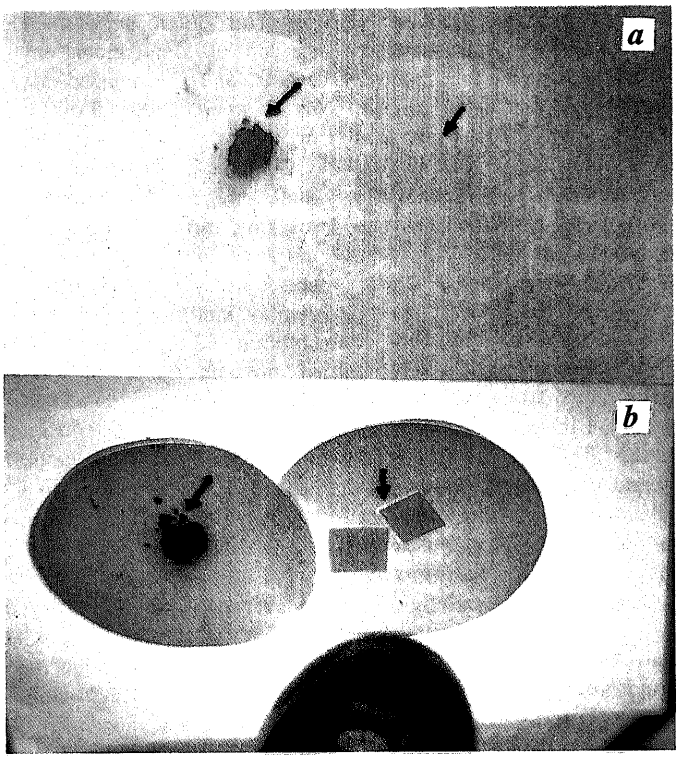

Figure 2. Optical colour photographs of visible light emission from CdS on filter paper taken at 300 K. *a*, Photograph taken under visible light. Orange colour crystallites are bulk CdS with band gap 2.405 eV and average size 75 nm. Faint yellow crystallites have band gap 2.97 eV and average size 5.0 nm. *b*, Photograph taken under UV radiation for samples as in *a*. The nanocrystallites emit visible red light whereas the bulk CdS does not.

We have prepared a batch of CdS samples of different crystalline size by a chemical bath deposition technique[2]. Optical absorption spectra at 300 K of two CdS samples (bulk and nanocrystalline) are shown in Figure 1. The band gap for these two samples is found to be 2.405 eV and 2.97 respectively. It is noted that in case of nanocrystalline CdS film there are several absorption maxima in the form of oscillations which is a signature of the size quantization effect. From the blue shift[3], the average radius of CdS nanocrystallites was estimated to be 5.0 nm. Depending upon the crystalline size, we could change the band gap from 2.4 eV to 2.97 eV which is significant.

Since our nanocrystalline CdS semiconductor has band gap 2.97 eV, it has to be doped to achieve light emission. However, Rutherford Back Scattering analysis show excess Cd in the nanocrystallites, which in principle should act as autodopant in CdS (ref. 2). Thus, if these nanocrystallites are now excited with higher energy photons, one expects to see visible light emission whose colour would depend upon the crystalline size and the trap levels present within the band gap of the nanocrystalline semiconductors. The optical colour photograph of bulk CdS powder and nanocrystalline CdS prepared on filter paper taken under visible light is shown in Figure 2 *a*. The orange colour powder corresponds to bulk CdS of crystalline size ~75 nm and the faint yellow colour slices corresponds to nanocrystallites of size ~5.0 nm. The same samples are exposed to UV light at 300 K and the photographs are shown in Figure 2 *b*. It is observed that the bulk-CdS powder does not emit any light and look black whereas the nanocrystalline samples emit red light. Our CdS nanocrystallites are unique of their kind – which clearly demonstrates the possibility of light emission only from such nanocrystallites of average size 5.0 nm. Thus, our CdS nanocrystalline materials can now be used as an UV sensor.

Xylanase production and its impact on bleaching of hardwood kraft pulp

Traditionally, wood pulp used for paper making process is bleached using chlorine or its derivatives such as calcium hypochlorite and sodium hypochlorite to remove residual lignin present in the pulp. The main cause for brown colour of the pulp is the presence of residual lignin. Chlorinated organic compounds produced during conventional pulp bleaching are detrimental to environment and highly resistant to microbial degradation. Chlorinated organic compounds are mainly responsible for the discharge of AOX (adsorbable organic halogens) in the receiving waters[1]. Modern techniques such as prolonged kraft cooking, bleaching with hydrogen peroxide, oxygen, enzyme (xylanase) and ozone have been introduced recently to reduce the production of chlorinated organics during bleaching[2]. Among the new techniques, enzyme bleaching is becoming important in the recent past due to its environmentally friendly nature[3–5]. In kraft pulping, xylan, one of the major components of wood hemicellulose, is solubilized during the initial stages of the cooking period and in the final stages of pulping, xylan gets precipitated and redeposited on the secondary cell wall of the fibre. The redeposited xylan acts as a bonding material between residual lignin and cellulose present in the pulp[4]. Therefore, limited hydrolysis of the xylan present in the pulp by hemicellulase enzyme like xylanase was found to improve the bleaching performance, reduce AOX discharge and active chlorine consumption in bleaching process[3,6–10]. Therefore, efforts were made to produce xylanase enzyme and apply to mill-made hard wood kraft pulp in our laboratory.

Table 1. Optimized conditions for the production of xylanase enzyme by *Trichoderma* sp.

Parameter	Condition
Corn cobs	15.0 g/l
Peptone	15.0 g/l
$(NH_4)_2SO_4$	2.0 g/l
KH_2PO_4	5.0 g/l
$MgSO_4$	0.3 g/l
$FeSO_4$ ($7\,H_2O$)	0.25 g/l
pH	6.5
Temperature	Ambient
Tap water	1000 ml

Several fungi were isolated from the stored bagasse from the bagasse yard at TNPL mill site using malt extract agar medium. All the fungi were screened for xylanase production using culture medium containing 1% xylan from bagasse chemical pulp[11], 0.5% peptone, 0.2% $(NH_4)_2SO_4$, 0.5% K_2HPO_4 and tap water, in orbital shaking incubator (160 rpm) at room temperature. Xylanase enzyme assay was carried out using 1% 4-*o*-methylglucuronoxylan from birch wood (7,500 Roth Germany) as a substrate in 50 mM sodium citrate buffer, pH 5.4 and temperature 40°C (ref. 12). Among the various fungi screened for xylanase activity, a wild strain of *Trichoderma* sp. (TNPL-192) was found to produce more enzyme when compared to others and the same was used for further studies.

To improve the xylanase production all the media components and conditions such as pH and temperature were optimized using Graeco-Latin technique. Various less expensive and easily available ligno cellulose substrates were tried and it was found that corn cobs, as carbon source, could induce substantial amount of xylanase production by *Trichoderma* sp. Xylanase production was scaled up in 5 l (operating volume 3.7 l) laboratory fermenter (Bioengineering Switzerland) using optimized medium (Table 1). The initial pH of the medium was 6.5 and allowed to vary during fermentation period. Temperature and PO_2 were maintained at 28°C and 8.0% saturation respectively. After 6 days of cultivation the crude culture filtrate had a xylanase enzyme activity of 108 XU/ml.

Crude xylanase enzyme produced in the fermenter was used for pretreatment of mill-made hard wood kraft pulp (kappa no. 17.8; brightness 24.4% ISO; viscosity 12.6 cps) prior to chlorination stage in CEH bleaching (C: chlorination, E: extraction and H: hypochlorite). The enzyme pretreated pulp along with control was bleached in the laboratory under identical conditions. The pulp properties such as kappa number and viscosity were performed as per TAPPI test methods T 236 and T230 respectively and brightness using Elrepho 2000 as per ISO 2470.

The bleaching results including bleaching conditions are presented in Table 2. From the results it is clear that xylanase enzyme pretreatment improves the bleaching response of hard wood pulp. Overall there is 4.4% ISO brightness increase over the control and

Table 2. Influence of xylanase pretreatment on bleachability of hard wood kraft pulp

Particulars	Control		Enzyme treated	
Enzyme stage (X)				
Xylanase enzyme applied XU/g	–		10	
pH	6.0		6.0	
Chlorination stage (C)				
Chlorine as Cl_2 % applied	3.20		3.20	
Consumed	3.13		3.06	
Final pH	2.2		2.1	
Extraction stage (E)

Hypo as Cl_2 % applied	1.92		1.92	
consumed	1.38		1.70	
pH Initial	9.8		10.2	
Final	8.6		8.7	
Final brightness % ISO	77.3		81.7	
Brightness gain	–		4.4	
Viscosity cps	5.4		5.0	
Bleaching conditions:				
	X	C	E	H
Temperature (°C)	50	Amb	60	40
Time (min)	120	30	60	120
Consistency (%)	10	3	8	8

enzyme pretreatment has insignificant influence on viscosity of the pulp, which indicates that it did not have much pure cellulose degrading enzymes. Generally, xylanase enzyme pretreatment is used to improve the brightness target in total chlorine free and elemental chlorine free prebleaching or to reduce the active chlorine components during the bleaching by reduced chlorine dosage to save chemicals and decrease the AOX production. In the present study we have applied the xylanase enzyme prebleaching concept to improve the final brightness of the pulp without any additional chemical charge Similar to the present study, enzyme pretreatment before the peroxide delignification/bleaching is also found to improve the final brightness of various pulps[9,13].

From the above results it is concluded that introduction of xylanase enzyme pretreatment stage, (10 XU/gram of pulp) in CEH bleaching of hard wood kraft pulp before chlorination stage would improve final brightness of pulp without any additional chemical charge, resulting in lower pollutant generation. The pulp properties are unaffected.

Greater fertility of *Drosophila ananassae* flies possessing high number of sternopleural bristles

Drosophila ananassae, a cosmopolitan and domestic species, is of common occurrence in India. It occupies a unique status in the whole of genus *Drosophila* due to certain peculiarities in its genetic behaviour[1]. The work done on population genetics, behaviour genetics and crossing-over in *D. ananassae* by Indian workers has been reviewed by Singh[2]. We conducted investigations on quantitative genetics with respect to sternopleural bristle number in Indian *D. ananassae*[3–5] and the results have shown that there is a genetic heterogeneity in Indian populations of *D. ananassae* with substantial amount of additive genetic variation for this trait

Table 1. Results of fertility tests for different selection lines (low line – L_1 and L_2; high line – H_1 and H_2; stabilizing line – S_1 and S_2)

Lines	Total number of females tested	Number of progeny produced	Mean number of progeny per female	Average of two replicates
L_1	33	528	16.00 ± 3.24	17.66 ± 2.34
L_2	33	638	19.33 ± 3.41	
S_1	33	689	20.91 ± 3.93	20.33 ± 2.21
S_2	34	671	19.74 ± 2.17	
H_1	35	1326	37.89 ± 4.55	37.33 ± 2.97
H_2	35	1287	36.77 ± 3.89	

Table 2. Comparison of mean number of progeny/female between different selection lines by means of *t*-test

Selection lines	Mean number of progeny/female	*t*-value	df	*P*
High line	37.33 ± 2.97	5.156	134	< 0.001*
Low line	17.66 ± 2.34			
High line	37.33 ± 2.97	4.564	135	< 0.001*
Stabilizing line	20.33 ± 2.21			
Low line	17.66 ± 2.34	0.820	131	> 0.05
Stabilizing line	20.33 ± 2.21			

*Significant.

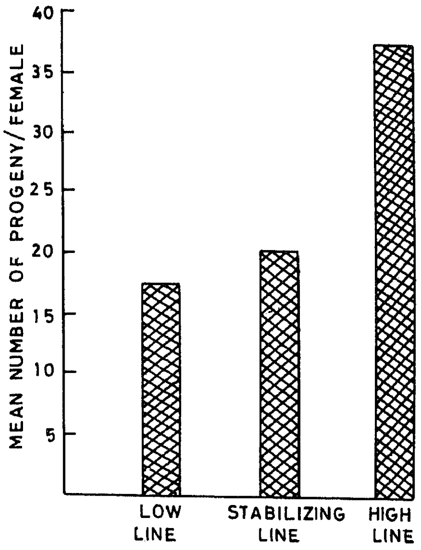

Figure 1. Mean number of progeny produced per female in low, stabilizing and high lines in *Drosophila ananassae*.

which is under polygenic control. There is also a positive response to directional and stabilizing selection for sternopleural bristle number which lends further support for polygenic basis of sternopleural bristle phenotypes in *D. ananassae*[4,5].

We conducted artificial selection experiments for high and low number of sternopleural bristles for 13 generations in *D. ananassae*. Separate high (H_1, H_2) and low (L_1, L_2) lines could be established[5]. We also conducted stabilizing selection experiments for bristle number for 15 generations and two replicates (S_1, S_2) of stabilizing selection line with intermediate bristle number could be established[4]. Mating success of *D. ananassae* flies possessing high and low number of sternopleural bristles was studied by direct observation in mating chamber and the results have shown that the females and males with high number of sternopleural bristles are more successful in mating than those with low number of bristles[6]. In order to test the effect of sternopleural bristle phenotypes on fitness in *D. ananassae*, fertility tests were carried out with flies having high (H_1, H_2), low (L_1, L_2) and intermediate number (S_1, S_2) of sternopleural bristles and the results are reported here.

Flies used in fertility tests were taken from two replicates of high line, two replicates of low line (after G_{13} of directional selection) and two replicates of stabilizing line (after G_{15} of stabilizing selection). From each line, virgin flies were collected and aged for about seven days. For pair mating, flies having known bristle number were taken from each line (in high line, females and males having more than 23 bristles were selected, in low line, females and males possessing less than 14 bristles were selected and in the case of stabilizing line, females and males having 17 bristles were selected). Each pair was placed in a fresh food vial for two days in order to mate. They were transferred into fresh food vials after mating. Three days later they were transferred to another set of food vials and again after three days, the flies were transferred to fresh food vials. Three more days afterwards, the flies were discarded. Thus there were three sets of vials (total time 9 days) for counting the progeny. The number of flies emerged in each vial was counted and the total number of progeny produced by a single female in 9 days was calculated. Mean number of progeny per female was calculated for low, high and stabilizing selection lines and *t*-test was performed to compare the fertility of flies in different selection lines.

A total of six lines were tested for fertility and the results are given in Table 1. The total number of females tested in different lines varies from 33 to 35. The mean number of progeny produced per female in different lines varies from 16.00 (L_1) to 37.89 (H_1). The average of two replicates shows that the flies having higher number of bristles produced more progeny than the flies having lower number of bristles. However, the mean number of progeny per female in stabilizing selection line is less than the high line but more than the low line. Figure 1 shows the mean number of progeny produced per female in high, low and stabilizing selection lines.

A comparison of mean number of progeny produced per female between different lines was done by means of *t*-test (Table 2). It is evident that the difference is significant ($P < 0.001$) between high and low lines and also between high and stabilizing lines ($P < 0.001$). However, the difference in mean number of progeny between low and stabilizing lines is not significant ($P > 0.05$). These results indicate that the flies having more bristles have greater fertility than those with low and intermediate number of bristles. Although the difference between low and stabilizing lines is not significant statistically, the flies from stabilizing selection line produce more progeny and show higher fertility than the low line flies.

It has been found that *D. ananassae* flies possessing high number of sternopleural bristles are more successful in mating than those with low number of bristles[6]. Thus *D. ananassae* flies with high number of sternopleural bristles are more successful in mating and also show greater fertility than the flies with low number of sternopleural bristles. This provides evidence for a positive correlation between sternopleural bristle number, mating propensity and fertility in *D. ananassae*.

Chronic arsenic toxicity in West Bengal

I have read with interest the paper 'Arsenic in ground water in seven districts of West Bengal, India – The biggest arsenic calamity in the world', by Mandal *et al.* (*Curr. Sci.*, 1996, **70**, 976–986). Without undermining the gravity of arsenic calamity in West Bengal, I believe that many figures presented in the paper are not based on materials and methods used for the scientific presentation. Materials investigated in the study are water samples of the affected villages and hair, nail, skin and urine samples of some of the people residing in those villages. No scientific epidemiological methodology was described in the paper. Under the circumstances, how was the figure of 20% of the people suffering from chronic arsenic toxicity due to drinking arsenic contaminated water arrived at? Similarly the statement that more than 200,000 people have skin lesions is conjectural. The figure may be much less or much more. Unless an epidemiological survey using statistically designed sampling method involving the whole affected region is carried out one cannot be sure regarding the total number of the affected people.

It needs to be emphasized that diagnosis of chronic arsenic toxicity on the basis of the only finding of diffuse melanosis is fraught with over diagnosis of dark complexioned rural population as suffering from the clinical disease. One is therefore not sure whether 60% of children of Madanpur village of Murshidabad are actually suffering from chronic arsenicosis.

It needs to be further stated that muscle biopsy is not done for the confirmation of diagnosis of chronic arsenic toxicity. Though detection of high level of arsenic in body tissues like nail, hair, skin scale in association of characteristic clinical manifestations of chronic arsenic toxicity confirm the diagnosis of arsenicosis, one can have definitive features of the disease in absence of elevation of arsenic level in those tissues.

We have recently completed an epidemiological survey of South 24 Parganas, one of the affected districts with financial assistance from Rajiv Gandhi National Drinking Water Mission.

We have observed typical raindrop pigmentation of the skin and thickening of the palm and soles characteristic of chronic arsenicosis in 8.82% (152) and 3.64% (368) respectively among 4171 persons who were drinking arsenic-contaminated water (0.05–3.2 mg/l). On the other hand, pigmentation was found in 13 cases and thickening of palm and sole in 4 cases out of 3235 persons drinking water having arsenic level between 0.01 and 0.05 mg/l. None of the 277 people drinking water having arsenic level less than 0.01 mg/l had any pigmentation of skin or keratosis.

Since 1983 we have investigated 248 patients suffering from chronic arsenic toxicity due to drinking arsenic-contaminated water and attending our Post Graduate Medical Institute. The common presenting features found in these patients were rain-drop pigmentation (94.35%), thickening of palm and sole (65.3%), dyspepsia (65%), cough with or without expectoration (62.5%) and burning sensation of the eyes (29.8%). Important physical signs were anaemia (43.9%), hepatomegaly (76.6%), splenomegaly (29.4%), rhonchi and crepitations of the lung due to restrictive and/or obstructive lung disease (30.24%) and polyneuropathy (8.04%). Skin cancer was found in 2% of the case.

The clinical manifestations of chronic arsenicosis as observed in West Bengal are varied and more severe than those observed in other parts of the world.

D. N. GUHA MAZUMDER

Department of Gastroenterology,
Institute of Post-Graduate Medical
Education and Research,
Calcutta 700 020, India

Mandal et al. reply:

We appreciate Guha Mazumder's comments but some clarifications are necessary.

For the last 2 years the School of Environmental Studies (SOES) is studying in detail *only one block* out of 55 arsenic affected blocks of 7 districts. The study is made on the anticipation that the results of a detailed study in one block may permit extrapolation of the situation of other blocks. Some blocks according to our survey report are known as seriously affected, like Domkal in Murshidabad, Kaliachalk in Malda and some blocks not so much affected as Baruipur and Sonarpur in South 24-Parganas and moderately affected are some blocks as Basirhat I, Deganga of North 24-Parganas. We have chosen Deganga block for a detailed study. Table 1 summarizes a detailed survey report of Deganga block for a two-year period.

Table 1. Survey report of Deganga block under North 24-Parganas*

Parameters studied	
Total area of Deganga	201.05 sq. km
Total population of Deganga	234142
Total no. of Gram Panchate (G.P.) in Deganga	14
Total no. of G.P. where arsenic in water above 0.05 mg/l	14
No. of G.P. where arsenic patients were detected	10
Total no. of Mouzas	108
Total no. of Mouzas where arsenic in tubewell water more than 0.05 mg/l	93
Total no. of tubewells in Deganga (almost)	15000
Total no. of tubewells analysed for arsenic	8500
% of the tubewells having arsenic within 0.01–0.049 mg/l	18%
% of the tubewells having arsenic above 0.05 mg/l	40%
Total shallow tubewells in use for agriculture (recently started this work)	110
% of the shallow tubewells having arsenic above 0.05 mg/l	43%
Total no. of school tubewells analysed for arsenic	84
% of the school tubewells having arsenic above 0.05 mg/l	50%
Total no. urine samples analysed	4867
% of urine samples having arsenic above permissible limit (40 µg/1.5 l/day)	86%
Total no. of nail samples analysed	1450
% of nail samples having arsenic above permissible limit (1.08 mg/kg)	78%
Total no. of hair samples analysed	1360
% of hair samples having arsenic above permissible limit (1 mg/kg)	48%

* For the last 2 years seven persons are engaged six days a week for survey work in Deganga.

Table 2. Analytical report of water, hair, nails and urine of South 24-Parganas district*

Sample	Total no. of samples analysed	Total no. of samples having arsenic above maximum permissible limit	Percentage of samples having arsenic content above maximum permissible limit	Range from above maximum permissible limit
Water	458	249 (above 0.05 mg/l)	54.37	0.05–2.22 mg/l
Urine	467	232 (above 40 µg/1.5 l/day)	49.68	40.00–9375 µg/1.5 l/day
Hair	509	274 (above 1 mg/kg)	53.83	1.00–7.43 mg/kg
Nail	464	246 (above 1.08 mg/kg)	53.02	1.08–57.4 mg/kg

Maximum permissible limit of arsenic in drinking water : 0.05 mg/l.
Normal range of arsenic in hair : 0.08–0.25 mg/kg.
Normal range of arsenic in nail : 0.43–1.08 mg/kg.
Normal range of arsenic in urine : 5–40 µg/1.5 l/day.
* These are the results of a joint project of School of Environmental Studies with D. N. Guha Mazumder in epidemiological study of South 24-Parganas.

It is clear that 234,142 people were consuming tubewell water from 15,000 tubewells (our survey reveals that most of the people drink tubewell water). On an average, 40% of the total tubewells we have surveyed (8500) contain arsenic above 0.05 mg/l, leading to the estimate of 93,600 people in Deganga block alone drinking arsenic-contaminated water. Assuming conservatively only 50% of the value we have calculated is correct, then even 2.55 million people were drinking arsenic contaminated water above 0.05 mg/l in 55 blocks.

Chakraborti and Saha[1] studied the incidence of arsenical dermatosis in 14 villages of West Bengal in 1987. Dermatosis was characterized by diffuse and palmoplanter melanosis and keratosis. According to their study the lowest arsenic concentration in water producing dermatosis was found to be 0.2 mg/l. In our study at Deganga block, about 7.3% tubewells have arsenic concentration above 0.2 mg/l. So, at Deganga block about 17,000 people are drinking arsenic-contaminated water and according to the study of Chakraborti and Saha these people, i.e. about 18% of the people drinking arsenic-contaminated water may have dermatological symptoms. We mentioned at the very beginning that Deganga is a moderately-affected block in seven districts. So our observation of about 20% of the people showing arsenical skin lesions out of the total people drinking arsenic-contaminated water in West Bengal may not be ruled out.

In West Bengal the affected villagers are farmers and they consume a high amount of water (5–6 l per day). Several studies all over the world provide quantitative toxicity data in human following chronic oral exposure to arsenic. Taking together, these studies clearly indicate that chronic intakes of about 10 µg/kg/day or higher may result in dermatological and other signs of arsenical toxicity[2]. The study of Chakraborti and Saha identified a Lowest Observed – Adverse – Effect-Level (LOAEL) of 18 µg As/kg/day of dermal and hepatic effects. This value is strongly supported by several other studies that identified similar LOAEL values: Hindmarsh *et al.*[3] LOAEL = 19 µg/kg/day; Cerbrian *et al.*[4] LOAEL = 14 µg/kg/day; Abernathy *et al.*[5] LOAEL = 14 µg/kg/day.

Table 4 of our published paper in *Current Science* reports that approximately 20% of the population exposed to arsenic-contaminated water in Taiwan, Chile, Argentina, Mexico, Thailand have arsenical skin lesions. This is similar to our prediction that 20% of the total population drinking arsenic-contaminated water above 0.05 mg/l (1.1 million) may have arsenical skin lesions. Also our survey in many villages shows that up to 40% of the people have arsenical skin lesions. In one such village (Shanpukur, Deganga) D. N. Guha Mazumder went with us and we found that 40 people out of 60 we surveyed had arsenical skin manifestation. The dermatological study carried out in Deganga over the last 2 years will be published soon.

Further, D. N. Guha Mazumder reports that recently he has completed an epidemiological survey of South 24-Parganas, one of the affected districts with financial support from Rajiv Gandhi National Drinking Water Mission (RGNDWM). In fact, one of us (DC) is a co-investigator on this project and all water (458), hair (509), nails (464),

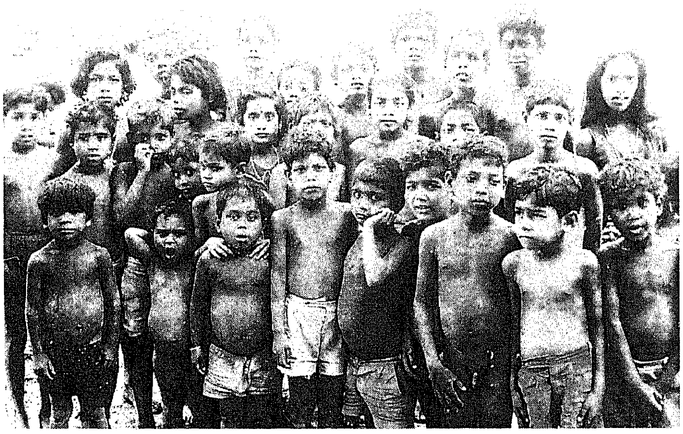

Figure 1.

urine (467) were analysed in our laboratory. Table 2 shows the water, hair, nail, urine analysis report of an epidemiological survey in South 24-Parganas. A large population who have no skin manifestation but high arsenic in hair nails, urine may be subclinically affected. The report of Guha Mazumder to RGNDWM states that, he has identified arsenical skin lesions in some people drinking water containing arsenic in the range 0.01 to 0.05 mg/l.

Although the WHO recommended value in drinking water is 0.01 mg/l, many countries including India believe 0.05 mg/l is the safe limit. Thus according to Guha Mazumder even if people get arsenical skin lesions drinking arsenic-contaminated water from 0.01 to 0.05 mg/l then the magnitude may be much higher than we anticipated.

In response to the comment 'Findings of diffuse melanosis is fraught with over-diagnosis of dark complexioned rural population as suffering from the clinical disease', we like to state that due to over length of the paper we could not provide the details of analysis of hair, nail and dermatological symptoms of the Madanpur village children. Table 3 gives the arsenic in hair, nail and dermatological features of some of the children and Figure 1 is the children of Madanpur village having arsenical melanosis (60%).

The following points will further explain the relation of dermatological symptoms and arsenic toxicity.

Pigmentations and arsenical toxicity

In the art of diagnosis of a disease, history is of prime importance followed by clinical examination findings which have to be confirmed by laboratory and other investigations. Findings of one clinical sign without correlation of the other two (history and investigations) never points to the disease. There are

Table 4. Area-wise family distribution of arsenical dermatosis

Village	District	No. of families	Population	No. of the affected family	Percentage	Total members of the affected family	No. of the affected persons	% of affection	
								In village	In family
Gangapur, Barasat	North 24-Parganas	68	243	11	16.18	55	23	9.46	41.82
Ramnagar	South 24-Parganas	24	248	10	41.70	63	58	23.00	92.10

Kachua, Binimoypara, Habra	North 24-Parganas	35	148	22	62.90	116	75	50.70	64.70
Kalobari, Habra	North 24-Parganas	39	168	17	43.59	101	36	21.43	35.64
Madra	Bardhaman	12	763	3	25.00	14	13	17.10	92.86
Charmajdia	Nadia	15	83	3	20.00	35	18	21.69	51.43
Gopalnagar, Karimpur	Nadia	7	51	7	100.00	51	44	86.27	86.27
Katlamari,	Murshidabad	48	335	44	91.67	317	175	52.24	55.20
9	5	270	1471	104	49.63	831	482	35.77	58.00

too many causes of isolated melanosis (diffuse or spotted) as well as isolated keratosis (diffuse or spotted). A clinician should never call racial pigmentation (i.e. Africans), dark coloured persons, solar melanosis, drug-induced melanosis, haemochromatosis, suprarenal deficiency (Addisson's disease), ochronosis, xeroderma pigmentosa and many other hyperpigmentary conditions as arsenical melanosis, because there are distinctive diagnostic criteria of each condition. The differentiating features of arsenical melanosis from all other hyperpigmentary states are taught to the students of dermatology.

When both melanosis and keratosis are present in the same patient, the problem of diagnosis becomes simplified pointing to arsenical dermatosis but these features are not present during birth or before 2 years.

As the keratin layer of palms and soles is thick compared to that of soft skin of body, palms and soles remain non-dark in dark skinned persons which becomes dark in some pathological melanotic states, easily recognized by comparing with the palms of unaffected dark persons.

In Mandapur village arsenical melanosis was pointed to the acquired darkening of palms, not from general pigmentation alone. These were confirmed by high arsenic in nails and hair (Table 3).

Arsenical melanosis is an acquired condition contrary to racial, genetic and other congenital pigmentations.

Clinical expression

From the analysis of arsenical dermatosis in 9 villages in 1985 by K. C. Saha (Table 4) it can be easily seen that all the individuals of the affected family do not have clinical signs of the disease though many of them later on developed the clinical disease if the intake of contaminated water was continued.

Many of these apparent normal subjects show high arsenic in nails, hair and skin scales proving their subclinical arsenical toxicity.

In my grouping of the stages of arsenicosis, the different stages of clinical expression have been clearly mentioned e.g. (i) Chemical or transient phase, (ii) Subclinical or persisting phase, (iii) Clinical melanosis phase, (iv) Clinical melanokeratotic phase, (v) Phase of internal complications (liver, muscles and other organs), (vi) Carcinoma.

Though arsenicosis is a generalized disease, clinical expression in skin appears earlier than the complicating phase of internal toxicity.

Muscle biopsy

For the diagnosis of arsenical toxicity, easy available tissues like skin scales, nails and hair and skin biopsy are recommended rather than routine muscle biopsy, liver or kidney biopsy.

HEP research in the Indian context

I wish to make a few comments on the special section on high energy physics (*Curr. Sci.*, 1996, **71**, 109–127) in this note. G. Rajasekaran says that new ideas for particle accelerators have to be discovered or there will be an end to HEP by about 2010 AD. Is Indian science ready to entertain new ideas? The idea to discuss HEP in the 21st century itself is not new; it is a borrowed one. Ramachandran lists outstanding questions for the early 21st century suggested by Gross, Witten and Kane. There is nothing wrong in relying upon experts, but the country's science leadership almost always follows the frontiers set in the West. It is unfortunate, but true, that the research environment in our country is so sterile and conformist that an original mind has to opt out of the system to sustain creativity. I doubt, if C. J. Joshi whose leading contribution in the plasma beat wave accelerator has been noted by A. Sen, would have got necessary support had he been in India.

Idea-wise, I think alternatives to the experimental philosophy embodied in the 1911 Rutherford scattering experiment might be worth looking at. After all, the aim of HEP is to search for a fundamental entity and foundational theory; and for that maybe going to higher and higher energies doing Rutherford scattering-like experiment is not the right choice. A plethora of elementary particles could be just the energy clumps created due to accelerating fields, having no fundamental significance. Why cannot a few massless particles be the building blocks of matter? Though neutrino oscillation and finite non-zero mass are of current interest in view of the unresolved solar neutrino problem, a neat theory with massless neutrinos could be envisaged for composite structure of photon and this together with the electron, might be the basic constituents of matter. De Broglie did consider this hypothesis, however, at that time muon neutrino was not known and the objections to this idea essentially originated from quantum theory, and the massive photon predicted in this theory conflicted with massless photon. Recently the possibility of topological quantization as an alternative to quantum theory has been explored, and some significant advances in the knot theory made. In particular, the discovery of the Jones polynomial in 1984 which can distinguish mirror image of a knot, and Witten's physical interpretation given in 1988 using 2+1 dimensional field theory are important for the present discussion. One might revive the idea that neutrino is a space–time trefoil knot in the light of these new discoveries (H. Jehle in 1975 considered a trefoil model). These ideas are at present what Rajasekaran calls the 'crazy ideas', however, such alternatives need to be given attention since the physics at Planck energy and early universe is very speculative, and the standard model has at least two major drawbacks, i.e. large number (as many as 20) of adjustable parameters and mathematical weakness of dealing with infinities in renormalization procedure.

Rajasekaran's proposal for a task force of a mutidisciplinary team of experts for new discovery in accelerators is endorsed by Ramachandran. In the most successful laboratories the world over, this approach has been in practice since long; unfortunately in India such proposals adorn the recorded speeches of eminent scientists, and are seldom implemented. Unless the problems at implementation level are sorted out, the think-tank proposal by Rajasekaran is likely to remain wishful thinking.

Ramachandran notes the criticisms voiced against heavy funding for doing science for the sake of it, and tries to justify public support for HEP, citing its impact on other branches of science and high-tech fall-outs of accelerator R&D. In 1994, the *CERN Courier* highlighted the spin off and technology transfer from HEP research. Hoffman in an article (*CERN Courier* 1994, **34**, 7–14) provided an exhaustive discussion on the subject. My question is: what is the spinoff of HEP in India? Ramachandran has not given any example from India. Unless a definite 'market value' in terms of indigenous technology development is specified, the proposal for building high energy accelerator (in the range of 10 GeV–20 GeV) shall be an avoidable burden on the public funding.

S. C. TIWARI

1, Kusum Kutir,
Mahamanapuri,
Varanasi 221 005, India

Rajasekaran and Ramachandran reply:

S. C. Tiwari's comments appear to be somewhat obtuse, generally lamenting on the poor impact of Indian science. The special section on the contrary, is a status report on High Energy Physics in the global context, although it includes some suggestions relevant to this country. The criticism that proposals such as research on new methods of acceleration are seldom implemented in India is a valid one. The point of repeating such proposals, nevertheless, is the hope that it will stimulate some young minds to think in this direction. It may be appropriate to mention here that for the first time, a School on Accelerator Physics is going to be held in India (School on 'The Physics of Beams' at the Centre for Advanced Technology, Indore, 13–25 January 1997). Hopefully this will be the first step towards the goal of generating new ideas on particle acceleration.

Instead of pursuing the beaten track of scattering-type experiments, can one envisage alternative experimental routes to deeper regions of space–time? This is an interesting question. However, Tiwari's list of speculations on basic structure does not answer this question. They are rather vague and even if they could be made a part of a consistent theoretical structure, they also have to be confronted by experiments. What is required is a new experimental paradigm.

We shall not enter into the broader question of public support to fundamental science here. It is an important question already discussed at various fora.

Ecological economics – Towards a synthesis of two disjunct disciplines

M. K. Pandit

The basis of all human activity is the use of natural resources, which also constitute the basic life support system. All economic activity, directly or indirectly, derives its sustenance from the environmental resources. The correlation between economic growth and natural resource depletion has of late attracted the attention of economists, but they form only a minority. The present article addresses basic issues leading to differing perceptions among ecologists and economists as far as economic growth is concerned and also tries to explore how this gap could be narrowed. The paper also reviews in brief some of the most recent international debates relating to ecological economics. The intricate problems of economic evaluation of ecosystems and the difficulties encountered in this process have been highlighted.

THOSE of us who were fortunate to have gone through the special issue of *Ecological Economics*[1] would agree how a meaningful dialogue between ecologists and economists has attempted to bridge the wide gap between the two most dominating disciplines of the twentyfirst century. This process had, however, started much earlier with the works of Costanza and Daly[2], Costanza[3], and Maxwell and Costanza[4]. The Asko meeting, organized by the Beijer International Institute of Ecological Economics in September, 1994 in the archipelago outside of Stockholm, was an important landmark in further concretization of this process of dialogue and consenus. The participants included eminent economists and ecologists and the dialogue resulted in a joint article by the distinguished scholars, led by Kenneth Arrow, which got published in *Science*[5]. However, Robert Costanza, a co-author of the Arrow *et al.* article, in his introductory essay on 'Economic growth, carrying capacity, and the environment' in the special issue[1] has outlined the reason that 'like any consensus statement, Arrow *et al.* leave many things vague and only scratch the surface of many others[6]'. It was, therefore, logical to elicit further response to the paper from a group of invited scholars, who could feel free to offer positive, negative or both responses which is not possible in a consenus group. These responses were slated to be published in three separate journals and one of them is *Ecological Economics* which is being discussed here. One of the commentators[7] in the issue pointed out that the article by Arrow *et al.* was some sort of 'dog bites man story', in the context of 'the article's authorship, novelty of the concept and the journal's prestige and readership'. That was perhaps the reason it initiated a debate and a discourse which could have academic implications on one end and possibly political on the other. However, in terms of the novelty, it does not seem to be a 'man bites dog story' as was said to be. There are indications of such a thinking in economics much earlier. Here it would be interesting to refer to an obituary essay by Herman E. Daly[8] who, while paying tribute to his distinguished teacher, Nicholas Georgescu-Roegen, mentioned that there was a great need for introspection among economists, who refuted Georgescu's revolutionary ideas not by reasoning, but rather by keeping silent or making 'the lame remark' that his recent work was 'not really economics'. The revolutionary ideas were contained in Georgescu's *Entropy Law and the Economic Process*[9] and *Analytical Economics*[10], but even after three decades standard economics textbooks have ignored these reformist ideas of Georgescu-Roegen. Daly in this essay has drawn the readers' attention to Paul Samuelson's Preface to *Analytical Economics* in which he referred to Georgescu-Roegen as a 'scholar's scholar', an 'economist's economist' and eulogized him elsewhere by saying, 'I defy any informed economist to remain complacent after meditating over this essay'. But what was preached was never practised. Samuelson's 'influential textbooks', to quote Daly, have not contained a trace of Georgescu's ideas. Why, for example, was it not possible for the concept of 'entropic flow' to occupy the core of economic theory? The 'circular flow' continued to have sway over economic policy because in this path it was theoretically possible to achieve a continuous economic growth through abstract exchange value (debt, purchasing power) which has no physical dimension[8]. For example, the circular flow diagram conveys the meaning of the economic process as an iso-

---

M. K. Pandit is in the Centre for Inter-disciplinary Studies of Mountain & Hill Environment, University of Delhi South Campus, Benito Juarez Road, New Delhi 110 021, India.

lated circular flow from the manufacturers to the users and back again, without any inlets or outlets. In sharp contrast is the Georgescu-Roegen's view of one-way flow which begins with resources and ends with waste. He called it 'entropic flow' and highlighted its role in the maintenance of economic process. In his analysis he brought out clearly that the entropic flow necessarily induces changes in the environment on which it depends, because what is released as waste is qualitatively different from what is taken in[8]. Georgescu also explained that inclusion of physical dimension in the circular flow of economic process had not been considered at all by economists. Georgescu-Roegen used the second law of thermodynamics or the entropy law to explain the matter–energy flow in economic process by relating it with the environment in terms of resource utilization and production of waste. Consider conversion of soil (clay) into bricks which are then used for construction of a building and one can in no way retrieve soil from the concrete mass. Also add to the process amount of energy used up in converting clay into bricks. The system, therefore, ends up with taking in low entropy energy-matter and producing high entropy energy-matter. Daly argues that growth in entropic flow encounters physical barriers like depletion, pollution and ecological disruption. Since, in mainstream economics, growth in GNP has been treated as synonymous with the economic growth, it has been impossible to set limits to which resources can be exploited and converted into capital. Georgescu-Rogen considered substituting capital for resources, an idea propounded by the neoclassical school, as the cardinal sin of economics. He therefore, could not perhaps expect a better deal from his peers. So much for the 'disciplinarian' attitudes.

Ecology and economics

There is a highly striking similarity between physical sciences and economics, of course via mathematics, in achieving results through submission to experimental data and their verification by empirical evidence. Also that when 'economic phenomena are analysed thoroughly they display existence of regularities which are just as striking as those we find in physical sciences'[11]. It is this virtue of economics which has been exploited in the past and also in the present day neoclassical thinking. For instance, the theory that the resource constraints of entropic flow can be overcome by substituting capital for resources owes its origin to the Cobb-Douglas type production functions. But in reality how much substitutability is possible between fund and flow remains a moot question! Conversion of resources into capital would follow that not only more capital is required for the purpose, but also more resources are needed to generate fund flow. More production to generate capital would also result in depreciation, depletion, pollution and disruption. In the words of Daly, 'to conceive of capital as a near-perfect substitute for resources, as is frequently done under the influence of Cobb-Douglas type production functions, is to believe that one can make the same house with twice as many saws, but half the lumber. Not to mention the problem that more saws require more resources for their production[8]'. It is on this count of over-mathematization of economics and the elevation of technique over substance[12] that has, in a way, led to the wedge between ecology and economics.

Biology in general and ecology in particular, compared to other scientific disciplines, seem to exhibit lesser regularities/generalities which could be analysed and forecast. 'Ecology has deep-rooted characteristics that make its problems more difficult to solve than, for example, those of physics[13]'. Therefore, modelling exercises and projections, derived through mathematical equations, for solving ecological problems, more often than not, fall flat while dealing with the intricacies of life phenomena. Since problem solving is a difficult task in ecology, some authors have defined it as 'the most intractable legitimate science ever developed[13]'. Consider extrapolation of an observation made on one organism to all organisms inhabiting the same ecosystem. For instance, temperate forests in Alps and Himalaya harbour *Sorbus aucuparia*, cannot be generalized to mean that biotic communities of the two biomes are similar. Similarly, populations of a species, distributed in time and space, may have similar genetic make up, but differ greatly in their ecological properties. Prediction of likely habitats of these species-populations, using analytical tools, simply does not work because populations of same species may inhabit extremely contrasting habitats. A practical weakness of the approach, using regularity or generality as a basic criterion in problem solving in ecology, is that predictions generated are not sufficiently precise to answer specific questions about specific individuals and localities. Similarly, theories like sigmoid population growth equation, also known as logistic or Verhulst-Pearl equation, are 'pedagogically useful but not applicable to specific situations, because they ignore such complications as age distributions, time lags and nonlinear interactions that characterize actual populations[14,15]'. The problem is further complicated when equations and the analyses derived from these are applied to complex life-form situations like ecosystems.

One such analysis, based on equations and extrapolations, which has of late attracted great attention among economists and biologists alike, relates to environmental and natural resource accounting. A plethora of literature is now available on the subject of system of national accounts (SNA) and a review of the debate was published by UNEP in 1993 (ref. 16). In the majority economic view, the basic assumption in the whole SNA analysis revolves around the GNP as the index of growth, which in turn is based on the quantification of goods and services, and stocks and flows. There is, however, a growing realization among economists that if the welfare of future generations is to be kept in mind then the net national product (NNP) is a better index than GNP. These economists[17] are of the view that 'changes in stocks of natural resources have typically not been included in the SNA. As many of these resources generate essential life supporting services, their exclusion may severely distort the NNP estimates. It should be of highest priority to try to include changes in the complete asset base in the accounts'. Even for estimation of NNP, in the ecological context, the evaluation will embrace the natural capital, which is an ecosystem or the species therein. For estimation of NNP, it is natural that, while taking care of the ecological constraints, we must resort to shadow pricing of goods and services of an ecosystem. To achieve this sub-goal it is necessary to build demand supply curves for the various ecological functions. A number of methodologies are being attempted internationally to evaluate ecological functions in terms of services, but agreement on these seems a remote possibility, even among economists[16]. It is extremely difficult to build demand supply curves, precisely because we are unable to know how and which functions to quantify in an ecosystem. Applying economic tools of shadow pricing would involve methodologies like opportunity cost, revealed preferences, willingness to pay and accept, travel cost and many more. All these methodologies suffer from one basic flaw – they are all anthropocentric and thus ignore all real natural functions of an ecosystem. It can be argued here if there can be any other view than 'anthropocentric' in economics. At the outset it seems extremely difficult and impracticable, but in long range view, economics cannot escape from the reality that the resources, which form the feed of economy, cannot be exploited unsustainably for long. Economics has to be on the lookout for alternate development paths, which are sustainable. Carrying capacity based development and the holistic context of institutional economics are some of the useful approaches for achieving sustainability[18,19].

On a somewhat transformed note the neoclassical school believes that after all one can quantify most of the variables operating within an ecosystem and model the effect of different scenarios that could arise and, therefore, select a development path that could be termed as sustainable. As stated above, whatever be the methodology this analysis cannot escape the basic bias towards human species and the subservience of all other life to it. Let us take an example of a terrestrial ecosystem and consider whatever could be natural functions of a pristine ecosystem and then let us also find out what are human aspirations linked to this ecosystem (Figure 1).

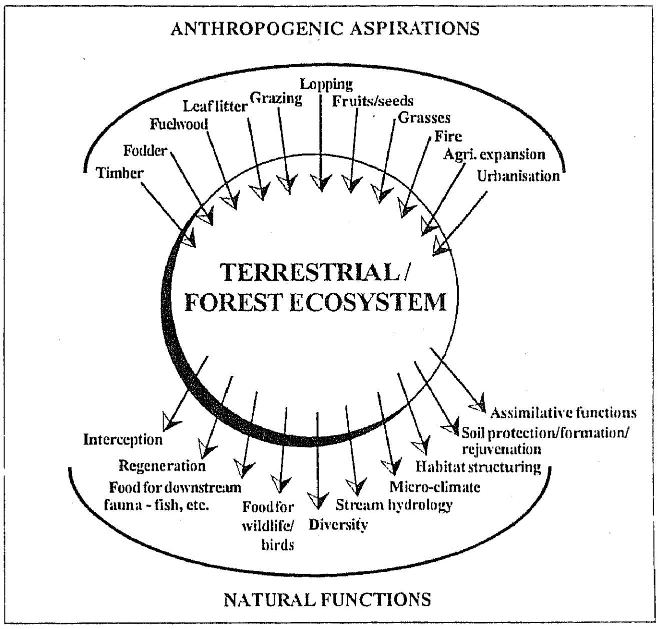

Figure 1. A simplified summary of anthropogenic pressures on a forest ecosystem and its natural functions. Note the diversity of natural ecosystem functions ranging from maintenance, regulation, habitat structuring, assimilation, etc. Any one or a mix of human activities as shown in the top of figure can severely damage or reduce the natural functions, which in turn would destroy the very base on which that human activity depends. Such natural functions, therefore, cannot be ignored while attempting natural resource accounting.

Table 1. Components included in modified forest accounts

Yield	Maintenance	Stock
Timber	Maintenance	Forest inventory
Harvest of berries		Berry-yielding herbs
Mushroom		Mycelium
Meat (bag)	Game protection	Game population
Recreation	Various activities	Various
Biodiversity	Fauna/flora protection	Survival conditions
Effects on hydrological flows	Measures that affect run off	Forest inventory, bare lands, ditches, etc.
Fixing of carbon	Silviculture and boarding (non-harvesting)	Carbon pools
Buffering of acid rain, tree nutrition	Liming, fertilization	Content of exchangeable base cations in soil and vegetation
Nitrogen leaching	Construction of nitrogen sinks	Nitrogen-fixing capacity
Reindeer forage		Lichen stocks

Source: ref. 20.

From an economic analysis point of view, accounting in a natural ecosystem is done broadly for its functions like production/yield, maintenance and stock (see Table 1). When we try to understand the natural ecosystem

Table 2. Modified NNP accounts for income from Swedish forests, 1987

Market value of timber	18.63
Inputs from other sectors	–3.14
Stock growth	3.8
Silviculture	– 1.55
Subtotal 1	17.74
Berries	0.5
Mushrooms	0.55
Meat from game	0.47
Subtotal 2	1.52
Biodiversity	– 0.6
Carbon pools	3.8
Exchangeable cations in soil	– 0.6
Lichen stocks	– 0.02
Subtotal 3	2.58
Total net income	**21.84**

functions as outlined in Figure 1, it would be clear how little justice we do to ecology by evaluating or accounting only that which is of direct benefit to *Homo sapiens*. The natural functions listed in the Figure 1 may again only be a miniscule of the total processes operating and products being generated within that ecosystem. The evaluation leaves no scope for assessment of countless interactive processes which operate on a time-scale varying from millionth of a second (at molecular level) to millions of years (at ecosystem level). Table 2 represents the results of an exercise some authors[20] in Sweden carried out based on the components selected for accounting as shown in Table 1. One can, almost instantly, see a dichotomy between the desired outcome and the actual outcome. It is only timber, berries, mushrooms and meat from game which are added to accounts. However, the most important part, the biodiversity, which has made all other functions possible is subtracted, as if it were a liability on the system. Timber, berries, mushrooms and meat all consumed by man, are therefore, not natural functions of an ecosystem to the extent that man has extricated himself from this ecosystem through a 'civilizational process'. His dependence on forest produce cannot be equated with that of a tiger, elephant or a reindeer. Man's relation with the forest is increasingly becoming a unidirectional process, while that of wildlife is dynamic and losses and gains flow both ways.

What is, therefore, important is the understanding that *the wood* is not timber alone. What is also important is that inventory of species, as outlined in Table 1, cannot be accounted separately; the *parts* cannot be summed up as a *whole*. A forest cannot be treated like a car whose chassis, engine, gear box, etc. can be accounted individually and then totalled into an entity called car. What needs to be appreciated is that a structure we term as an ecosystem is the product of millions of years of interactions and adjustments among its components, and its biotic and the abiotic characteristics. Therefore, evaluating only a tiny fraction of this vast organism, spread both in time and space, can only be a notional exercise. The results of such an exercise, based on half truths, are going to be grossly misleading. The argument that some data, which can be bad data, is better than no data[21] is bad in intent in the same way as bad economics cannot be better than no economics. The reason is preference, while accounting, to some data like timber or non-forest timber produce over other species of seemingly modest standing in a natural ecosystem. It leads us to a situation where it becomes terribly bad ecology. In a natural ecosystem there are no preferential treatments – the high and the lowly, the mighty and the meek, are allocated resources on an equitable basis. The evidence for this comes from the fact that in a climax natural ecosystem it is generally *K-selected* species, which co-exist with a high degree of species diversity, and leave enough resources and space for others to prosper. In sharp contrast is the situation of the highly-disturbed ecosystems where it is mostly *r-selected* species, which are weedy, allelopathic and dominate to oust others. Applying classical or neo-classical economic approaches to ecosystem analysis for resource accounting would sharply bring into focus that face of economics which will juxtapose human selfishness with the co-existing nature of ecology operating in natural ecosystems. It is here that the role of eminent and influential economists can bring about a positive transformation, which shall not be perceived as correction of current and prevalent economic thought, but its evolutionary responsibility.

Keeping in mind the long term goal of sustainable development, many seminal thinkers of this century have discussed the relation between economic growth and environmental quality, and the link between economic activity and the carrying capacity and resilience of the environment. The debate aimed at establishing a substantive dialogue among economists and ecologists for exploring the possibility of an interdisciplinary consensus on the issues of economic growth, carrying capacity and the environment is a well-directed step towards synthesis of the two disjunct disciplines[1,5]. These useful efforts have to be received with admiration, support and understanding, for that can help us in evolving a methodology that allows the coming generations of *Homo sapiens* and also our contemporary life-forms to feel secure and assured of life enjoyment as is intended in the best spirit of economic thought. It is in this context that economics can find ecology to be useful. Economics tends to assume that change takes place in a fairly continuous fashion, but change in an ecosystem may be of capricious nature resulting from the response to destabilizing factor/s rather than a process of graduated change[22]. From ecology we learn the lesson of 'holism'. In other words, if environmental responses to economic change have to be predicted, various interactions and links within and between ecosystems have to be fully fathomed. The concern – how can one dispense with the anthropocentric principle of value in economics and how can a 'holistic' state be accomplished – may be genuine. But if the aim of sustainable development has to be achieved, a realization must start in right earnest that 'ecologically bounded-possibilities of using natural resources are taken as a normative starting-point for the development of economic theory[18]'. There is a great and urgent need to strengthen the new school of thought based on an institutional framework. This framework shall neither be based on anthropocentric and close-ended mathematical models, nor on a reductionistic–mechanistic argument, but on a holistic, evolutionary, open-ended and pluralistic methodological paradigm. These reformist views[23] have started gaining acceptance among economists, though only in a limited way. If we fail in this endeavour then the existing imbalance of power in the society, which helps the 'vested economic interests to put their individual short-term aspirations ahead of the collective and long-term interests of a sustainable society', will continue to increase[18]. Our success will lie in forging towards an ecological-economics synthesis. Barbier *et al.*[24] have enunciated a number of steps to enable this synthesis. Better communication between different disciplines and development of interdisciplinary approach have been suggested to be the first step towards this goal followed by improved research collaboration between organizations and individuals. This aim could be an achievable one. After all there are many common grounds of meeting in ecology and economics – equity, resource allocation, micro-economics (welfare of individuals/species), macro-economics (welfare of populations/communities/ecosystems/biosphere), stocks, flows, goods, services, etc. These are not merely semantic similarities, but real scientific regularities shared by the two disciplines. Ecology and economics are not such aliens to each other as many sceptics may think.

ACKNOWLEDGEMENTS. I am grateful to Prof. Virendra Kumar for valuable suggestions and for providing facilities to work. I have greatly benefitted from the discussions with Mr. Pushpam Kumar on the economic aspects.

A glimpse into the fascinating world of fullerenes

T. Pradeep

Regional Sophisticated Instrumentation Centre and Department of Chemistry, Indian Institute of Technology, Chennai 600 036, India

Fullerenes, carbon nanotubes and onions have caught the imagination of the entire scientific community. The interest seems to be growing unabated; about two papers per day are being published today. This article sketches the fascinating area of this new allotrope of carbon, maybe the only allotrope of any element discovered in 20th century, focusing primarily on C_{60}. The early history, synthesis and characterization, mass spectrometry, derivatization, orientational ordering, pressure effects, superconductivity, magnetism and photophysical properties of fullerenes and fullerene-based compounds will be discussed. The science of buckminsterfullerene, and fullerenes in general, is still dominated by spectroscopy and chemical physics. Although many applications were proposed in the early days of fullerenes, many of them turned out to be disappointments. However, potential uses of fullerene-based materials in photophysical, biological and chemical applications are increasingly recognized.

THE role of serendipity in scientific discoveries is widely recognized. The story of buckminsterfullerene[1], C_{60} and fullerenes in general, is no exception. Scientists in their fascination to understand the chemistry of interstellar molecules, hit upon an unusual and most extraordinary discovery in the history of chemistry. The molecule they discovered had sixty equivalent carbon atoms which formed the pattern of a football giving it the highest symmetry. Theoretical predictions[2] of such structures were known from 1970. There is no molecule formed by the same atom in chemistry as big as buckminsterfullerene. Elemental carbon has been known for millennia to be occurring in two polymorphic forms, graphite and diamond. Graphite has two dimensional layers of sp^2 hybridized carbon atoms interlinked by weak van der Waals forces. Since the inter-layer interaction is weak, graphite is used as a lubricant. Diamond, however, is one of the hardest materials known to man. This property arises from the strong three-dimensional bonding in diamond in which each sp^3 hybridized carbon atom is bonded to four other similar atoms. Fullerenes constitute another allotrope of carbon, probably the first allotrope of any element discovered in recent times. Figure 1 shows the structures of graphite, diamond and C_{60}. There are also other all-carbon molecules similar to C_{60} with cage structure, collectively called fullerenes in honour of the famous American architect Buckminster Fuller whose geodesic domes are landmarks of 20th century architecture. There are other forms of carbon such as carbon rings[3] which are receiving considerable attention today.

The 1996 Nobel Prize in Chemistry was awarded to Sir Harold Kroto of University of Sussex, UK and Robert Curl and Richard Smalley of Rice University, Houston, Texas, for their work on buckminsterfullerene.

It was only natural for a molecule of such immense beauty to attract the whole of the scientific commu-

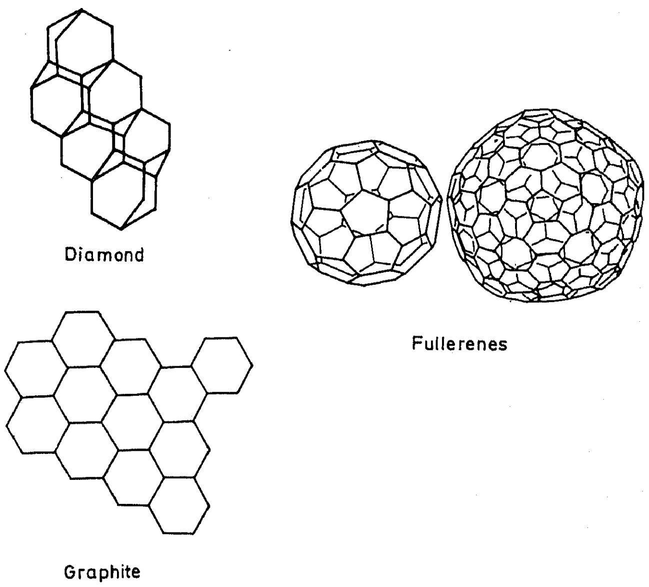

Figure 1. A schematic representation of the structures of graphite, diamond and fullerenes. While the two-dimensional sheets formed by hexagons are packed one over another in graphite, the diamond structure is three-dimensional. Only two fullerenes are shown. The smaller one is buckminsterfullerene, C_{60}. The bonds between hexagons are more like double bonds showing the corannulene-type substructure. The double bonds are localized exocyclic to the pentagons giving [5]radialene character to the pentagons and cyclohexa-1,3,5-triene character to the hexagons.

nity[4,5]. The structure, spectroscopy, chemistry, materials science and applications have been intensely investigated. Because of all these, buckminsterfullerene became the subject matter of nine out of ten of the most cited papers in chemistry in 1991. The position improved further in 1992 to make ten out of ten. According to statistics[1], one paper per week got published in this area from 1985 to 1990. After 1990, it is said do be one per day. In 1995, it was slightly less than two per day.

Molecules with 70, 76, 84 and other numbers of carbon atoms were soon characterized. Developments in 1991 showed that these molecules need not be found only with tens and hundreds of atoms but also with thousands of atoms. These giant molecules of carbon occur as nanometer size tubes and balls which are called carbon nanotubes and onions[6] respectively. A number of new geometries are proposed in recent researches[7]. The chemistry and physics of the new forms of carbon will continue to excite scientists in the coming years.

In this article, I intend to give an account of the chemistry, physics and materials science of this new form of carbon in a rather illustrative fashion. I may not present a balanced view of the subject matter as my own interests in the area are rather limited. There have been numerous conferences on fullerenes and even on specialized topics of fullerene chemistry and physics over the years. Several books[4,5] on fullerenes have appeared in the recent past and a comprehensive review in the limited space is nothing but impossible.

Discovery and early years

As noted earlier, the search for certain linear molecules of carbon normally found in the interstellar region called cyanopolyynes, was the starting point of this search[8]. Some of these molecules of the type H–C≡C–C≡C–C≡N or HC_5N have been synthesized in the laboratory. These molecules containing seven, nine and eleven carbons, were detected by radio-astronomy. However, studies of carbon arc have shown the presence of molecules containing as many as 33 carbon atoms. This was the time when Smalley and co-workers in Houston were working with a newly-developed cluster source[9] which used lasers for evaporation, supersonic molecular beam expansion for clustering and photoionization mass spectrometry for detecting the products. Similar studies were also done by Rohlfing *et al.*[10] in Exxon[10]. Their studies on graphite which preceded those of Smalley and colleagues showed the presence of carbon clusters heavier than C_{33}, but interestingly no odd number cluster was seen. Soon after the beginning of these measurements, it was observed that species such as HC_7N and HC_9N are formed in the reaction of C_n ($n < 30$) with H_2 and N_2. However, the major discovery turned out to be not the detection of cyanpolyynes but the unsually abundant species C_{60}, which dominated the mass spectrum under certain clustering conditions[11]. There were other heavier clusters too. It was found that these clusters were particularly unreactive compared to the lower clusters. Reactivity and photofragmentation studies showed that the 60 atom cluster is extremely stable. The observed chemistry could be explained if one assumes the graphitic sheet to transform into a hollow chicken-wire cage similar to the domes of Buckminster Fuller[12]. Such a closed cage requires that[13] $12 = 3n_3 + 2n_4 + 1n_5 + 0n_6 - 1n_7 - 2n_8 - \ldots$, where n_k is the number of k-sided faces. For carbon, the only values of k are 5 and 6, although 7 is also possible as has been detected recently in carbon nanotubes[14]. This means that there should be 12 pentagonal faces and the number of hexagonal faces are arbitrary. In C_{60}, there are 12 pentagonal faces and 20 hexagonal faces. Fullerenes, the class of closed cage molecules, have the general formula C_{20+2n6}. C_{60} has only one chemically distinct carbon atom. However, in C_{70} there are five distinct carbon atoms. In larger fullerenes there is the possibility of isomers and some fullerenes are also chiral. Very recent studies have shown that there are many isomers to some fullerenes than previously thought of[15]. However, because of the isolated pentagon rule (observed generally), which places pentagons separated by hexagons, the number of isomers is limited.

The experimental apparatus used in the discovery of C_{60} is shown in Figure 2. This set-up is now commercially available for the study of a variety of clusters. A rotating disk of graphite is irradiated with a powerful laser to evaporate carbon. As the laser falls on the disk, a stream of helium gas is passed over the disk by releasing a valve. The gas carries the evaporated carbon species with it and during its passage to the nozzle, the species in the vapour undergo clustering. The cluster

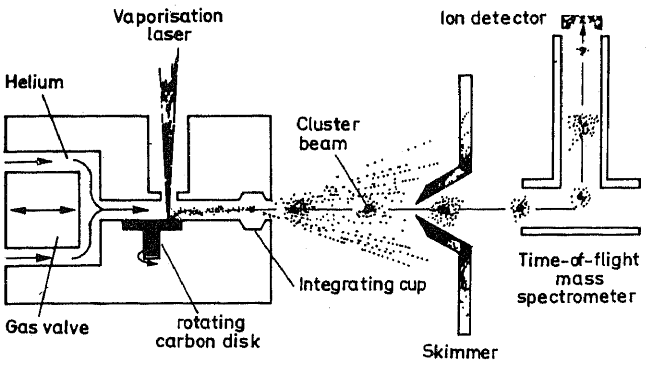

Figure 2. The experimental set-up used to discover C_{60}. The graphite disk is evaporated with a NdYAG laser and the evaporated carbon plasma is cooled by a stream of helium coming from a pulsed valve. The clusters of carbon are produced in the integration cup and are expanded into vacuum. The ions are detected by time of flight mass spectrometry (from ref. 1).

Box 1. Synthesis and purification of fullerenes

For the synthesis of fullerenes all that you need is a welding transformer, a chamber connected to a vacuum pump (even a single stage oil sealed rotary pump is adequate) and some graphite rods. The graphite electrodes are brought in close contact with each other and an arc is struck in an atmosphere of 100–200 Torr of helium or argon. To sustain the arc, a voltage of 20 V (AC or DC) may be necessary. For a graphite rod 6 mm in diameter, about 50–200 A current may be consumed. Generally, spectroscopic pure graphite of high porosity is used so that evaporation rate is high. The soot generated is collected on water-cooled surfaces which could even be the inner walls of the vacuum chamber. After sustaining the arc for several minutes, the vacuum is broken and the soot is collected and soxhlet extracted for about 5–6 hours in toluene or benzene resulting in a dark reddish-brown solution which is a mixture of fullerenes. 20–30% of the soot so collected is soluble, this soluble material is subjected to chromatographic separation[107]. Over the years, several simple methods have been discovered including the filtration technique over an activated charcoal–silica gel column[108]. About 80% of the soluble material is C_{60}, which can be collected in one pass using toluene as the mobile phase. C_{70} can be separated using toluene/*o*-dichlorobenzene mixture as eluant. Repeated chromatography may be necessary to get pure C_{70}. C_{60} solution is violet in colour while that of C_{70} is reddish-brown. Higher fullerenes C_{76}, C_{78}, C_{82}, etc. require HPLC for purification[109]. Spectroscopic properties of several of these fullerenes are now known. Normally, preparation of a gram of C_{60} requires about 5 hours of work. But many of the higher fullerenes require over 250 hours to make about 1 mg. C_{60} and C_{70} are now commercially available from several sources. C_{60} is about $175 a gram but C_{70} is not yet affordable for synthetic chemists. Therefore, a majority of the studies reported is on C_{60}. Fullerenes crystallized from saturated solutions retain solvent molecules and removing them may require long hours of vacuum drying. Crystal growth by vapour transport is an excellent method to grow millimeter size crystals devoid of solvent for sensitive measurements. For solid state spectroscopic measurements, it is better to use evaporated fullerene films in high or ultra high vacuum to avoid solvent contamination. Evaporation is also used as a method of purification as there is substantial difference in the onset of evaporation between C_{60} and C_{70}. Calixarenes (bowl-shaped macrocycles with hydrophobic cavities) have been used recently[110] in the purification of fullerenes. See Figure 4 for a schematic procedure of synthesis and purification.

Arc evaporation is not the unique way of making C_{60}. Fullerenes have been found in flames[111], upon chemical vapour deposition used to produce diamond[112], in a 1.85 billion year old bolide impact crater[113] as well as from spacecrafts[114]. It has also been made from diamond[115]. No one has made it by chemical reactions but such a possibility has excited many organic chemists[116]. It has been synthesized from camphor recently[117]. Mass spectrometry has shown that higher clusters of carbons could be formed by laser evaporation of polymers[118]. Highly unsaturated carbonaceous ring systems upon laser evaporation[119] produce C_{60}. There are several other exotic means of producing C_{60}. However, the total synthesis would indeed be a landmark in chemistry; approaches to this have been suggested[120].

Synthesis and purification was followed by the characterization of this material by a variety of spectroscopic techniques. The pivotal role played by mass spectrometry in characterizing fullerenes cannot be overemphasized. NMR showing a single line corresponding to the equivalence of the carbon atoms[22], single crystal X-ray structure resolving the atomic positions[121], characterization by UV/VIS (refs 107, 122), IR and Raman[123] spectroscopies, etc. soon followed. Predicted electronic structure was confirmed by HeI and HeII photoelectron spectroscopies[124].

beam emanating from the nozzle is selected by a skimmer. The clusters are then subjected to mass analysis by time of flight mass spectrometry. Under certain experimental conditions, the mass spectrum was very similar to that reported previously, showing a distribution of even-numbered species. But a variation in the experimental conditions, especially the introduction of the integration cup (see Figure 2), increased the intensity of the sixty atom cluster to such a point that in some experiments only C_{60} and C_{70} were seen (Figure 3).

At the same time, experiments were also done using a Fourier transform ion-cyclotron resonance (FT-ICR) apparatus. In this set of experiments, mass selected cluster ions were subjected to reactions with a variety of gases. C_{60}^+ was extremely unreactive to gases such as O_2, NH_3 and NO. On the contrary, clusters of other elements such as Si showed high reactivity. In fact no evidence was there to show that Si_{60}^+ was special. A body of other experimental data was accumulated by the Houston group on the photophysics, photodetachment

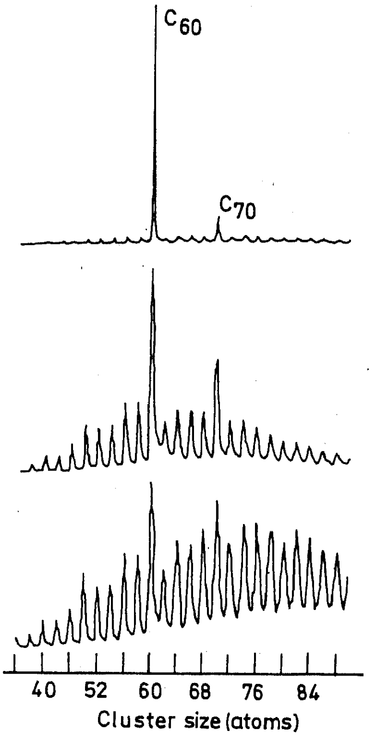

Figure 3. The mass spectrum of the carbon clusters under various experimental conditions. Under certain conditions, only C_{60} and C_{70} are seen (from ref. 1).

and optical spectrum of C_{60}. None of these studies gave any evidence to suspect the proposed structure.

For nearly five years, C_{60} was truly a chemical physicists playground. A large number of theoretical papers got published on the electronic structure[16], reactivity[17], magnetism[18] and a number of other properties of C_{60}. The studies were made easy by the very high symmetry of the proposed structure. In fact a close similarity between the observed peaks in the IR spectrum of an evaporated carbon soot and the theoretical frequencies[19] made Krätschmer and colleagues[20] look for C_{60} in the soot. They were working on laboratory-produced carbon soot in order to understand the interstellar spectrum of carbonaceous materials. The soot they obtained after evaporating graphite resistively in an atmosphere of helium contained four bands in the infrared region. The absorption frequencies correlated well with the proposed bands of C_{60}. Application of solvent extraction yielded significant quantities of fullerenes[21] from the soot and a host of techniques were applied to the characterization of this newly made form of carbon. For a description of the synthetic procedure, see Box 1.

Mass spectrometry and ion/molecule reactions

Soon after a method of macroscopic synthesis of C_{60}, several ion/molecule reaction studies were performed[22].

In the early days, fullerenes were expensive and mass spectrometer was the ideal reaction vessel. C_{60}^- and $C_{60}H^+$ were produced by chemical ionization (CI) with methane[23]. It was shown that C_{60}^- was 15 times more abundant than $C_{60}H^+$, consistent with the high electron affinity. Methane CI spectrum showed protonated fullerenes and adducts of fullerenes with C_2H_5. Collision-induced dissociation of C_{60}^+ in the keV range with helium showed the expected C_{58}^+, C_{56}^+, etc. fragments like in the earlier photofragmentation study. Fragmentation of C_{60}^{2+} yielded only C_n^{2+}, not C_n^+ in contrast to polycyclic aromatic hydrocarbons (PAHs) which undergo charge separation reactions. In addition to collision-induced dissociation (CID), surface-induced dissociation[24] was also performed. Collisions on both silicon and graphite surfaces showed that C_{60} does not dissociate appreciably at collision energies in the range of 200–300 eV. A number of studies have confirmed this unusual stability and has been attributed to the 'resilience' of the molecule. Similar properties have been predicted for its hydrides also[25]. C_{60} collision also leads to delayed ionization and thermionic emission[26]. Surface collision experiments have been reported on higher fullerenes and metallofullerenes as well[27]. Mass spectrometry has also been used to study thermodynamic properties of fullerenes[28].

In addition to the fragmentation, endohedral complex formation is also observed when high energy collisions are performed[29]. Eight keV collision of helium with C_{60}^+ produced a number of C_{n+4}^+ mass peaks. When the collision gas was changed to ^3He, the peaks shifted by one

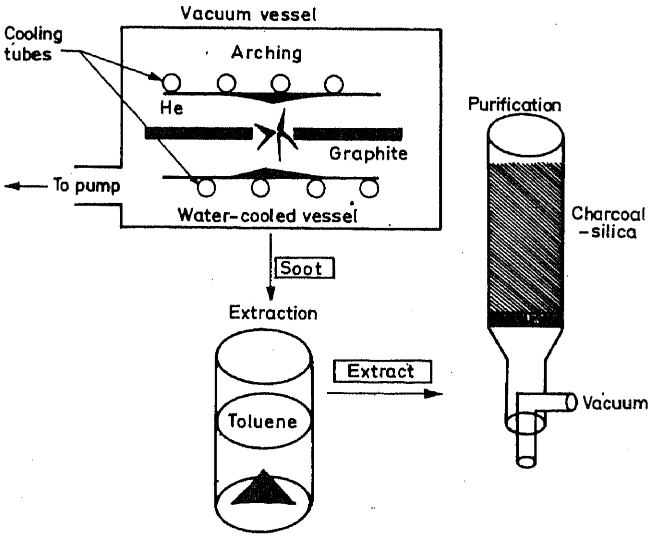

Figure 4. A schematic of the experimental procedure used to make gram quantities of fullerenes. The soot collected after arc evaporation of graphite is extracted with toluene and the soluble material is subjected to chromatographic separation (adapted from Rao, C. N. R. and Seshadri, R., in *Organic Molecular Solids* (ed Jones, W.), CRC Press, in press).

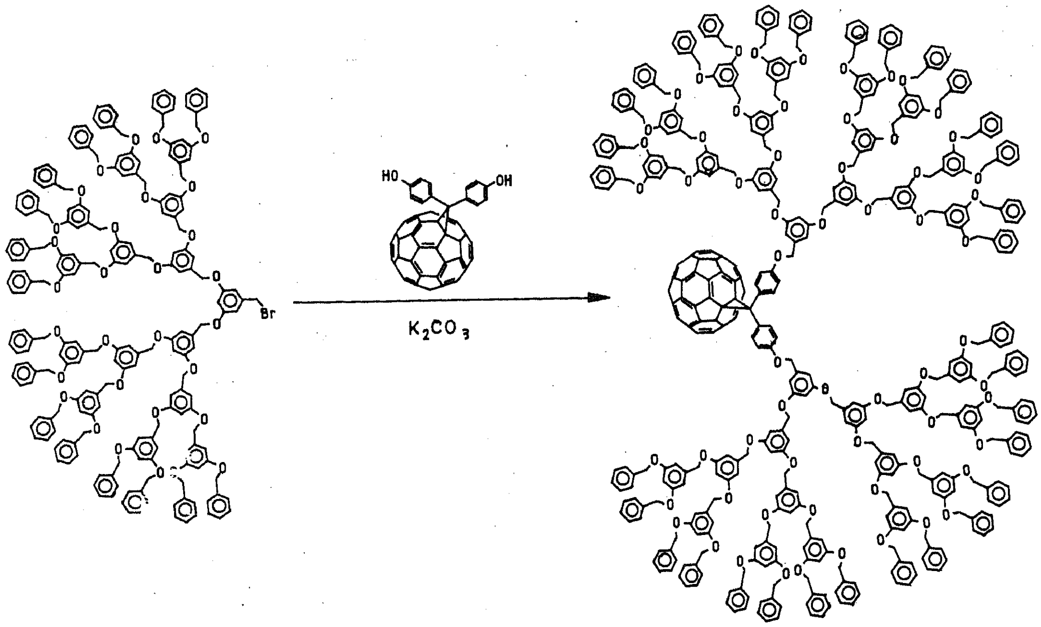

Figure 5. Schematic showing the synthesis of dendritic methanofullerene, using the established dentritic growth procedures (from ref. 132).

mass unit showing that the peak was due to the addition of helium atoms to C_{60}. Others did experiments in different types of hybrid tandem mass spectrometers and confirmed the results. Ion kinetic energy and CID measurements showed unambiguously that $He^+@C_{60}$ (the @ symbolism implies that the species prior to @ is within the cage of the fullerene after the symbol) is an endohedral complex. Similar measurements were repeated with C_{60}^{2+} and C_{60}^{3+}. C_{70}^+ and C_{84}^+ were also shown to form endohedrals. $Ne^+@C_{60}$ and $Ar^+@C_{60}$ are hard to observe in conventional spectrometers due to large energy losses, but they have been seen in specially designed instruments (see also the section on endohedral complexes).

In addition to the work on pure C_{60}, mass spectrometry has been used extensively to characterize the derivatives of C_{60} formed by reactions[30]. The identification of Birch reduction products of C_{60} was done with electron impact (EI) mass spectrometry. The products of C_{70} were also studied by EI. Reaction products with fluorine showed mass peaks at $C_{60}F_{36}^+$ and $C_{70}F_{40}^+$. These products fragment by elimination of F, CF_3 and C_2F_5. Methylated C_{60} showed products with 1 to 24 methyl groups. C_{60} and C_{70} were found to add to aromatic molecules such as benzene, toluene, xylene, anisole and bromobenzene[31]. (See Box 2 for a discussion of the chemistry of fullerenes.)

The fullerene cage itself could include other elements such as boron[32] and nitrogen[33]. Evaporation of boron nitride doped graphite disk produced boron doped fullerenes[32] such as $C_{60-n}B_n^+$ with $n = 0$ to 6. Photodissociation showed that these species are resistant to fragmentation, but reactions with ammonia showed the acidic behaviour of boron atoms. Species such as $C_{60-n}B_n(NH_3)_n^+$ were observed showing that boron has been incorporated into the cage. Substituted fullerenes such as $C_{59}NH$ are now prepared by synthetic chemistry[34].

Photoionization time of flight mass spectrometry has been used to show that clusters of C_{60} are indeed formed during vapourization[35]. Intensity anomalies in the mass spectrum have been detected corresponding to $(C_{60})_n^+$ where $n = 13$, 19, 23, 35, 39, 43, 46 and 55. The numbers suggest that the closed shell clusters $n = 13$ and 55 are probably icosahedra. The magic numbers are similar to the clusters of Xe and Ar. In Figure 6 we show the structure of the icosahedral cluster, $(C_{60})_{13}$.

Fullerenes undergo coalescence reactions in the gas phase. In laser evaporation of fullerene films, it was found that the mass spectra show peaks at very high masses above m/z 720 with enhanced intensities in the range of $(C_{60})_n^+$ (Figure 7)[36]. This proposes the fusion of C_{60} cages to form larger cage structures. The identity of the products was also studied by surface-induced dissociation, which showed that the clusters are hard to dissociate and no parent fullerene is formed. This excludes the interpretation that the peaks could be due to difullerene-like structures. The reaction is supposed to be taking place in the excited dense plasma. Similar coalescence reactions have been reported by others also.

Box 2. Chemistry of fullerenes in the condensed phase

Originally it was thought that C_{60} is an aromatic molecule because there are about 12,500 possible resonance structures. However, it should be remembered that in systems where pentagons are near hexagons, the system avoids double bonds in pentagons. The presence of double bonds in petagons reduces the bond distances, increasing the strain. For C_{60} there is only one structure which avoids double bonds in pentagons. This means that the delocalization of electrons is poor and C_{60} is poorly aromatic[125]. This 'poorly aromatic' classification immediately suggests certain type of chemistry. C_{60} can be visualized in terms of corannulene subunits with two distinct chemical bonds. The 60 6–6 bonds (between hexagons) with a bond length of ca. 1.38 Å have more double bond character than the 60 6–5 bonds (between pentagons and hexagons) of bond length ca. 1.45 Å; which are more like single bonds. This means that the pentagonal rings are extremely strained and insertion of a double bond in the 6–5 ring can bring in instability to the tune of 8.5 kcal/mol (ref. 126). However, describing its chemistry in terms of substructures such as radialene and paracyclene (see Figure 1) does not reflect the chemical reality fully since these substructures are planar while fullerenes are spherical. Fullerenes are strained and continuous and describing their chemistry in terms of a strained weakly aromatic molecule may be more appropriate[127].

Since fullerenes have only carbon atoms, substitution reactions cannot be done with them. However, such reaction could be done on its derivatives. The cages consist of sp^2 hybridized carbon atoms which have –I inductive effect. Therefore, fullerenes are strongly electron attracting and they react readily with nucleophiles and the reactions are similar to those of poorly-conjugated alkenes. The important problem is the number of addition products each reagent is going to bring about. A given product can also have a large number of structural isomers. Added to this, they may have very little solubility in organic solvents. Many of them do not have high stability due to the strain caused by the addition and therefore they may revert to parent fullerene under mass spectrometric examination. Only a few of them crystallize easily so that single crystal examination is possible. Added to this, the study has to be performed with very small quantity of material, often milligrams, although the situation has substantially improved in recent years. Sometimes, the purification procedures leave only tiny quantities of pure compound at the end. In many a case, purification of isomers is very difficult which makes complete understanding of the chemistry extremely time consuming, often impossible. Therefore, a large number of reactions are still not fully studied. However, there are certain investigations which stand out and have resulted in unique products. Because of its comparatively easy availability and due to its unique symmetry, C_{60} has been subjected to more detailed examinations.

Early electrochemical studies suggested that fullerene C_{60} undergoes six reversible reductions[128] corresponding to the complete filling of the t_{1u} LUMO. The early C_{60} chemistry revolved around this high electron affinity of the cage. Adducts of C_{60} with radicals, nucleophiles, carbenes and dienophiles have been reported. Functionalization leading to η^2 complexes of transition metals[129] was the early organometallic chemistry reported. Alkylation of C_{60} leading to methanofullerenes[130] is being intensely pursued by the groups of Wudl, Rubin and Diederich. A detailed account of this can be found in a recent book by Hirsch[5]. These reactions have been shown to result in fullerene polymers[131], fullerene dendrimers[132] (see Figure 5), fullerene-based HIV protease inhibitors[133], fullerene nucleotide conjugates[134] and a number of other potentially useful materials. The electrochemical and photophysical characteristics of fullerene adducts can be technologically interesting. Although the chemistry of C_{60} is intensely investigated, that of higher fullerenes is beginning to attract attention. Because of the presence of large number of non-equivalent bonds, the product distribution is more complex. Nanotubes of carbon are also subjected to solution phase chemistry in a number of laboratories[135].

Another type of reaction which has not been observed before has been the addition of C_{60} and C_2 in the gas phase[37]. In this study, a C_{60} film was bombarded by high energy ions. The mass spectrum of the produced ions shows peaks at C_{60}, C_{60+2}, C_{60+4}, etc. all the way up to C_{108}, the mass limit of the instrument as shown in Figure 7. This suggests that the C_n fragments add back to C_{60} in the region called 'selvedge', the region immediately above the condensed phase where ion/molecule reactions occur. In fact such addition reactions are shown to occur without any activation barrier[38].

Endohedral chemistry of fullerenes

The cavity in the 7 Å diameter buckminsterfullerene molecule has intrigued chemists ever since the discovery

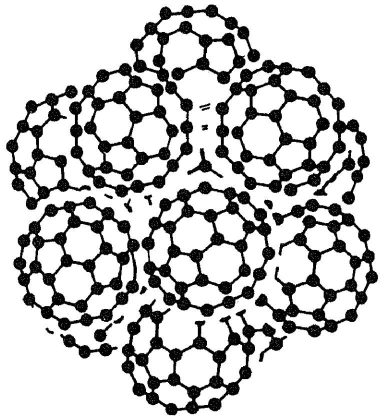

Figure 6. The icosahedral cluster $(C_{60})_{13}$ (from ref. 35).

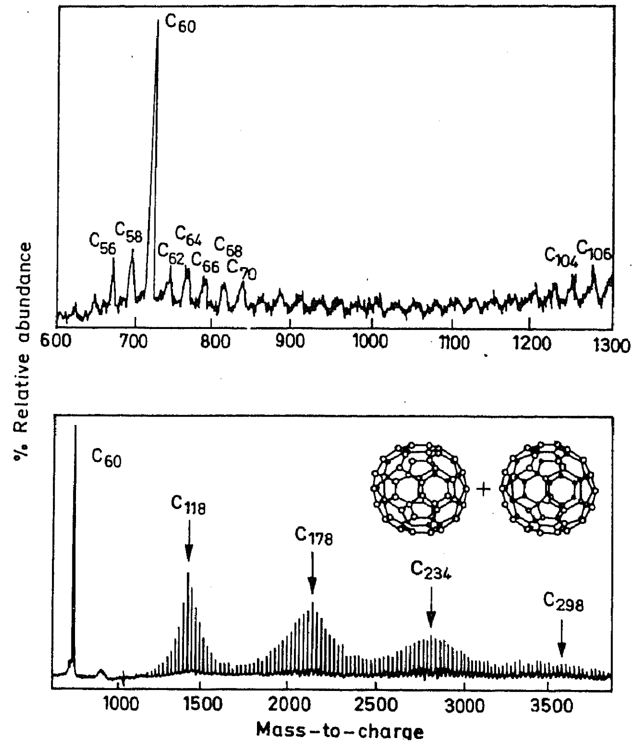

Figure 7. *Bottom*, Mass spectrum of a laser evaporated C_{60} film showing coalescence of fullerenes. Mass peaks are seen at $(C_{60})_n$ (from ref. 36). *Top*, Collision of high energy ions on C_{60} results in the addition of C_2 units to C_{60}. The mass spectrum shown here shows the addition of a number of such species (from ref. 37).

of fullerenes. Later, Smalley and colleagues[39] showed that laser evaporation of graphite impregnated with La_2O_3 can give La@C_{82} and the product could be extracted in toluene. The molecule was shown to be a radical exhibiting EPR hyperfine structure[40]. Mass spectral evidence for other endohedrals was soon available. High-energy collision experiments involving fullerene ions and noble gases were shown to result in noble gas encapsulated fullerenes[29]. For a substantial period of time, characteristic mass spectral fragmentation pattern was the only experimental evidence for the existence of endohedral fullerenes. The fact that He could be put into the cage prompted Saunders to probe the chemistry of endohedrals through ^{3}He NMR[41]. Rg@C_{60} (Rg = rare gas) molecules have been synthesized by a high temperature–high pressure method[42]. Studies showed the high diamagnetic shielding of the inner C_{60} surface indicating the existence of a high degree of aromaticity[43]. The ^{3}He endohedral chemistry is now being extended to the study of derivatives of C_{60} (refs 43, 44) and isomers of higher fullerenes[15]. Results show that there are at least eight C_{78} isomers and nine C_{84} isomers, much higher than originally suggested. La@C_{82}, La@C_{80}, La@C_{76} and a number of Y, Sc and Mn endohedrals have been prepared and purified. The electrochemical, electronic and magnetic properties of these materials have been investigated[45,46]. Gd@C_{82} is paramagnetic down to 3 K (ref. 47). There are theoretical predictions on the various electronic properties of endohedrals but experimental confirmation is awaited. A recent development in the endohedral chemistry is the preparation of Li@C_{60} by low energy ion-beam collision of Li^+ on a C_{60} film[48].

Orientational ordering

Of the several properties of fullerenes, a widely investigated aspect is the orientational ordering. Generally molecules of a high point group symmetry crystallize with a certain degree of orientational disorder. Some lower fullerenes are highly spherical and are held together by weak van der Waals forces, the molecular orientations need not be ordered as in the case of an ordered crystal. This high asymmetry is evidenced by the fact that large thermal parameters are necessary to fit the observed diffraction patterns. This symmetry is the reason why C_{60} had to be fixed with a handle by complexation to refine the atomic positions as was done by Hawkins[121].

In the pure form, because of its high symmetry and weak intermolecular interaction, C_{60} rotates freely in the lattice. This may lead to interesting properties such as the unusual flow of liquids over C_{60} film[49]. This rotation can be frozen at low temperatures, resulting in an orientational ordering. Upon reaction or by co-crystallization, which inhibits free rotation of C_{60} molecules, the atomic positions have been studied. At room temperature, C_{60} gives a sharp NMR signal at 143 ppm and the signal broadens at low temperatures as a result of chemical shift anisotropy[50]. This is due to the dynamic nature of the disorder, the orientational correlation times are of the order of 16 picoseconds. The orientationally

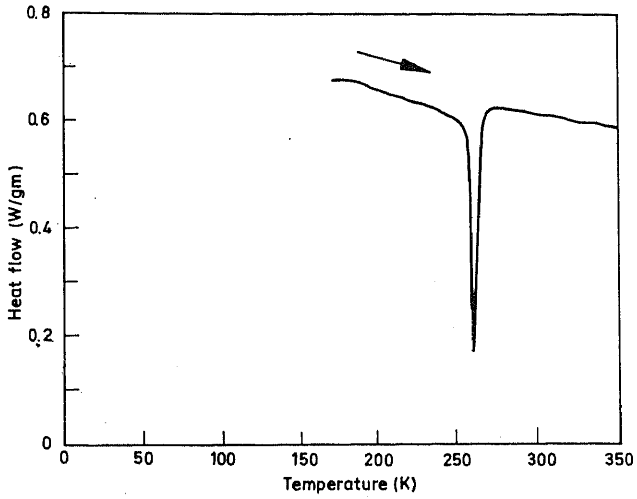

Figure 8. Results of a differential scanning calorimetric measurement of a powder sample of C_{60}. The arrow indicates that the data were taken upon warming (from ref. 51).

disordered fcc phase undergoes a transition to a sc phase at 248 K (ref. 51). In Figure 8, a differential scanning calorimetry trace of the transition is shown. In the sc phase, the rotation exists only along preferred axis. NMR studies have shown that below the ordering temperature the molecules jump between preferred orientations over a barrier of 3000 K (ref. 50). Phase transitions can be modelled which show that simple L-J potentials reproduce experimental behaviour. Charge-transfer effects are, however, important[52]. Neutron diffraction studies indeed provide a strong support to this suggestion in which it is found that the electron-rich bonds of one molecule are located close to the electron poor pentagon rings of the adjacent molecule[53].

Orientational ordering results can be seen in IR and Raman spectroscopies also[54]. A glassy phase has been observed around 80 K when molecular rotations are completely frozen[55]. It may be mentioned that many of the derivatives of C_{60} are also spherical and phase transitions of this type may be observed in them. Recently we have[56] observed such a transition in $C_{60}Br_{24}$.

C_{70} undergoes two phase transitions at 337 and 276 K and these transitions have been studied by IR and Raman spectroscopies[57]. Diffraction studies suggest a monoclinic structure for the lowest temperature phase and rhombohedral or hexagonal structure for the in-between phase[58]. Complete orientational freezing happens only at 130 K. Upon phase transition, the intramolecular phonons undergo hardening, a general feature observed for both C_{60} and C_{70}. Resistivity measurements have proved that there are two phase transitions in C_{60} and three in C_{70} (ref. 59).

Pressure effects

Both C_{60} and C_{70} are soft solids and their compressibilities are comparable to the *c*-axis compressibility of graphite. Upon application of pressure, the orientational ordering temperature increases at a rate of 10 K/kbar (ref. 60). Around 20 GPa, C_{60} undergoes a transition to a lower symmetry structure[61]. Above 22 GPa the material undergoes amorphization and the phase shows evidence for sp^3 hybridized carbon. In C_{70} amorphization happens around 12 GPa and only sp^2 hybridized carbon is seen[62]. This suggests that while polymerization via Diels–Alder addition might be happening in C_{60}, no such reaction occurs in C_{70}. Polymerization upon light irradiation has been observed in C_{60} (ref. 63). Under extremely high pressures, it is possible to convert C_{60} to diamond at low temperatures[64]. Such a conversion is seen in C_{70} also.

At fairly low pressures below the amorphization pressure, the photoluminescence band originally at 1.6 eV undergoes a redshift[65]. At a pressure of 3.2 GPa the band merges with the background, corresponding to the collapse of the photoluminescent gap. This arises due to the broadening of the HOMO and LUMO which is a result of shortening of the inter-molecular distance and concomitant increase in the interball hopping integral. This study has implication to the low temperature electrical properties found in doped fullerenes.

Conductivity and superconductivity in doped fullerenes

Doping with potassium, corresponding to the stoichometry K_3C_{60}, produces a superconductor with a transition temperature of 19.8 K (refs 66, 67) (Figure 9). The K_xC_{60} phase

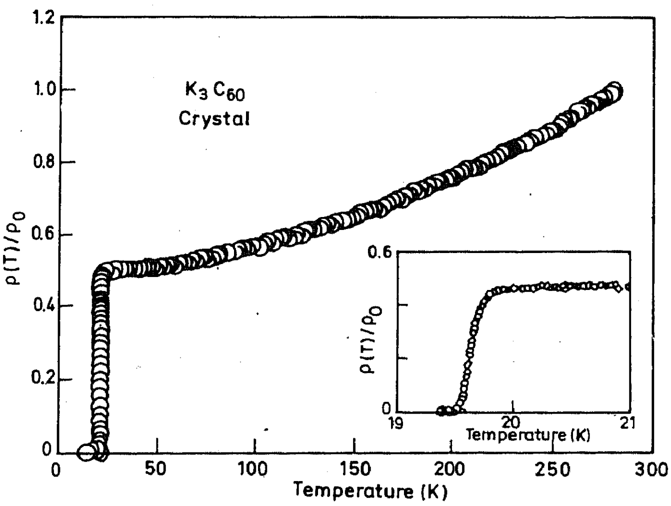

Figure 9. Normalised DC electrical resistivity (ρT) of a K_3C_{60} single crystal. The T_c observed is 19.8 K. ρ_0 is the resistivity at $T = 280$ K (from ref. 67). Inset shows the transition in detail.

was earlier found to be metallic[68]. It is interesting to note that doping graphite with potassium also results in superconductivity, but at extremely low temperatures. However, doping of Na and Li does not result in superconductivity, but other alkali metals do produce superconductors with higher transition temperature (T_c). Mixtures of metals also show the same phenomenon. Because the t_{1u} LUMO is triply degenerate, six electrons can be pumped into C_{60}. Six more can be placed in the t_{1g} LUMO. These electrons can be easily transferred from metal atoms placed in the tetrahedral and octahedral voids of fcc C_{60}. The highest T_c organic superconductor, Rb_2CsC_{60} has a T_c of 31 K (ref. 69). A_6B_{60} (bcc) and A_4C_{60} (bct) phases are non-superconducting[70]. Electron spectroscopy shows that continuous filling of the LUMO happens upon doping but on prolonged exposure, the LUMO band is shifted below E_f – making it an insulator[71]. Upon exposure to transition metals, the *d* states grow near E_f and incomplete metal to C_{60} charge-transfer is observed[72]. Studies show that T_c is a function of interball separation. Thus, intramolecular phonons are responsible for the superconducting ground states in these materials. Superconductivity in A_3C_{60} has been treated as a special case of BCS theory with intermediate electron-phonon coupling[73]. Ca_3C_{60} (ref. 74), Ba_6C_{60} (ref. 75) and Sm_3C_{60} (ref. 76) are superconducting. Superconductivity in higher fullerenes has not been reported, probably due to lower symmetry.

Ferromagnetism in C_{60}.TDAE

Another important property which arises as a result of change-transfer is ferromagnetism. Organic ferromagnetism is a rare phenomenon and is proved conclusively only in a few systems. So far there is only one donor which is shown to produce ferromagnetism as a result of complexation with C_{60}, which is TDAE, tetrakisdimethylaminoethylene[77]. The T_c observed is 16.1 K, which is the highest T_c found for an organic material so far. The material belongs to the monoclinic system with short C_{60}–C_{60} contact along *c* axis[78]. The quasi one-dimensional behaviour has been suggested by susceptibility measurements also[79]. Single electron transfer has been confirmed by EPR[79,80] and Raman studies[81]. Magnetic and electrical transport properties of C_{60}.TDAE have been reported on single crystals also[82]. A number of organic donors have been investigated for potential organic magnetism. Though all of them show pronounced magnetic correlation, no ferromagnetism has been reported[83]. In C_{60}.TDAE, spontaneous magnetization has been verified by zero-field muon spin relaxation technique as well[84].

Optical properties

C_{60} trapped in molecular sieves gives intense red light[85]. Light transmitting properties of C_{60} embedded silica films have been investigated[86]. C_{60} is found to be an interesting material for nonlinear optics, especially for third harmonic generation[87]. C_{60} derivatives would also be interesting in this regard. Third harmonic generation optical susceptibility of C_{70} film is interpreted in terms of the totally symmetric ground state along with two excited states; a one-photon state and a two-photon state[88]. Photoconduction and photoinduced electron transfer, optical switching properties and second harmonic generation are also thoroughly investigated. Several recent conferences have devoted exclusive sessions on the photophysics of fullerenes[89].

Two unusual properties

C_{60} shows anomalous solubility behaviour. Normal solutes show a linear temperature dependence of solubility. In most cases, the solubility increases upon warming. In inorganic systems unusual phenomena are seen due to solute–solvent interactions. Studies of solubility of C_{60} studied in a number of solvents indicate that there is a solubility maximum at near-room temperature[90] (280 K), dissolution is endothermic below room temperature and exothermic above. The results have been interpreted as due to a phase change in solid C_{60} modified by wetting due to solvent. Solubility maximum in organic materials is unprecedented.

Ordinarily materials have a critical point above which the distinction between liquid and solid disappears. The liquid is not seen below the triple point where solid and vapour coexist. C_{60} is one substance in which no liquid phase exists according to theoretical investigations of the phase diagram[91], although the question is still not resolved[92]. If at all such a liquid phase exists, it will be only at high temperatures above 1800 K where the molecules may not be stable.

Carbon nanotubes and onions

Fullerenes need not be found in spherical shape. Upon DC evaporation of carbon, the material deposited on the cathode was found to have tube-like structures of several nanometer length with closed tips[93] such as the one shown in Figure 10. Not only five and six but also seven-membered rings are found in these tubes. There can be single-walled tubes, but most common are multi-walled. These tubes are less susceptible to combustion; therefore, heating in oxygen is a method of cleaning them. The most essential feature of nanotube formation appears to be the presence of high electric fields at the tip of the tubes[94]. The presence of carbon–inert gas plasma make the growing tube end fluid-like. The mechanism is akin to the electrochemical growth processes. The growing tube end closes as a result of instabilities in the plasma. The tubes thus formed have been

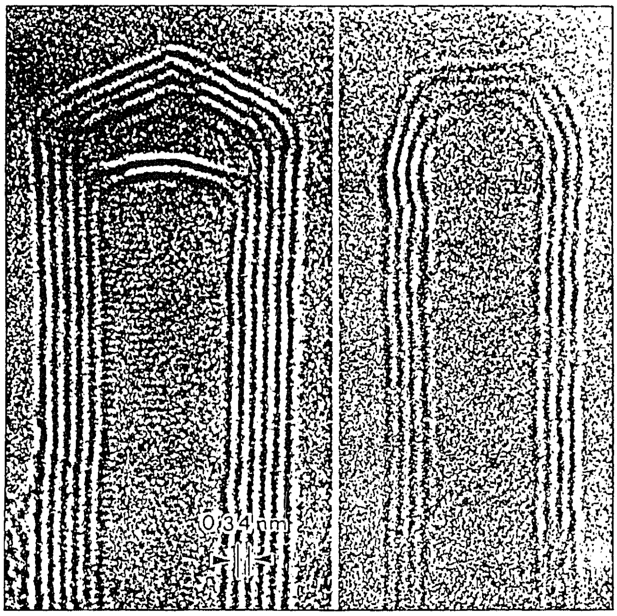

Figure 10. Bucky tubes of different dimensions. The figures are transmission electron micrographs. These are multi-shell tubes. The inner diameter and the length of the tube can vary. Along the body the tube is formed by hexagons and at the ends pentagons are required for closure (from ref. 93).

characterized by X-ray diffraction[95] and Raman[96] spectroscopy.

The structure of nanotubes makes their electronic properties very interesting. Calculations show that these materials could be good electrical conductors[97] and even superconductors (below 1 mK)[98] and the diameter of these tubes can be varied to tune the electrical transport properties. Experimental studies show that the tubes are semiconducting and the behaviour is similar to graphite[99]. Mechanically, the tubes do not have high aspect ratios, making them unsuitable for reinforcing purposes. However, experiments are underway to improve this parameter[100]. A recent application of nanotubes is their use in STM as contact tips.

Tubes can be filled with metals upon opening the tips with oxygen[101]. The probability of making nanoscale wires of metals has enthused many scientists. Lead has been put into the tubes by heating the tubes with lead oxide[95]. Such materials may have interesting magnetic properties[102]. Tube tips can also be opened by chemical methods such as boiling with HNO_3 and if boiled in the presence of metal salts, metals can be incorporated into the tubes.

Carbon onions are also formed along with tubes. These near-spherical large molecules are also found with single or multiple shells and can be filled with metal or metal-carbide particles[103]. Nanoparticles of metals could be placed in these onions so that they are resistant to oxidation, at the same time physical properties such as magentism are unaffected. It has been found that the electron beams of a TEM can be used to open the onion, stuff it with metal and empty it again[104]. It is also possible to use the onion shell as pressure vessels so that the graphite inside can be converted to diamond upon electron beam exposure[105].

Perspectives

The science of fullerenes is still dominated by chemical physics aspects. A quick glance through the literature of the past two years shows that organic chemistry of fullerenes is still in its infancy. The challenges involved in the characterization of derivatives are understandable and complete understanding of a particular reaction requires the application of several tools simultaneously. Therefore, it is very clear that chemical physics and related areas will continue to dominate fullerene research. Of course in the near future, carbon tubules and onions will add more colour to the physics and chemistry of carbon. Materials science of fullerenes is one area which has reached a certain stage of maturity and Indian contributions are particularly noteworthy[106]. Buckyball has brought delight to theorists and the excitements will continue. But it is a pity that in spite of the great many discoveries made, fullerenes have not made long inroads into other areas. C_{60} and its brothers have collectively caught our imagination and in effect it has become the most intensely researched single molecule of 20th century. Probably it may indeed be its greatest legacy.

In the present study we assessed plasma and platelet monoamine content using high performance liquid chromatography (HPLC). The study included 22 subjects consisting of 12 freshly-detected male diabetic patients and 10 age and sex-matched healthy controls. The same parameters were measured in streptozotocin-induced diabetic rat models consisting of controls, diabetic and insulin-treated diabetic rats. The platelet counts were significantly reduced ($P < 0.05$) in rat models as well as human diabetic samples. The plasma norepinephrine (NE) and epinephrine (EPI) concentrations were significantly increased ($P < 0.05$). The platelet showed a significant increase ($P < 0.01$) in NE, EPI and serotonin content. Increase in the plasma and platelet content of neurotransmitters may be due to increased sympathetic function, which is an adaptation for the decreased platelet count observed in our study. The results indicate that changes in the neurotransmitter content of the platelet may be a good index to assess the neurotransmitter status in pathological condition such as diabetes mellitus.

THE role of neurotransmitters in diseased condition has been studied using post-mortem brain samples which are often not reliable since conditions of collection and preservation of such samples are not uniform and there is hardly any choice of age, sex or status of disease. It has therefore become necessary to develop a peripheral model for studying neurotransmitter changes. The blood platelets can be used as a peripheral model since there are structural, morphological and physiological similarities between platelets and synaptosomes[1,2]. Platelets, like synaptosomes are limited by a membrane and contain mitochondria, storage granules, lysosomes, glycogen particles, microtubules and microfilaments[1]. They accumulate monoamines by an active transport mechanism located in the cell membrane and store high concentration of serotonin (5-hydroxytryptamine, 5-HT) in storage granules. The platelets and synaptosomes also possess monamine oxidase which metabolizes serotonin and other amines. Thus we have used platelet as a peripheral model and quantitated NE, EPI and 5-HT by HPLC method to assess monoamine alterations in diabetic patients and streptozotocin-induced diabetes in an animal model.

Three months old male Sprague-Dawley rats of ~180 g body weight were used for all experiments. They were housed in separate cages under 12 h light period and 12 h dark period. They were maintained on standard food pellets and tap water *ad libitum*. Diabetes was induced by a single intrafemoral dose (45 mg/kg body wt.) of STZ prepared in citrate buffer (pH 4.5) (refs 3, 4). The animals were randomly divided into three groups, i.e. controls, diabetic and insulin-treated diabetic groups with 4–6 animals in each group. The insulin-treated diabetic group received a daily dose (1 unit/kg body weight) of Lente insulin. The dose was increased daily according to the blood glucose level. Glucose was measured by GOD-PAP glucose estimation kits (MERCK) (Table 1).

Blood samples from diabetic patients were obtained from freshly-diagnosed cases with a fasting blood sugar level ranging from 150 to 200 mg/dl and with 1.5–2.0 mg urine sugar. None of the patients had any infection or secondary complications and were non-ketotic at the time of sample collection. Only male volunteers between age groups 40 and 60 were selected for the experiment. Patients with any other complications or on drugs were excluded from the study. The controls were age and sex matched.

About 10 ml of blood was collected from human volunteers by ante cubital venipuncture into 1 ml of Alsever's solution (acid/citrate/dextrose pH 5.0). Platelets were prepared according to the method of Steven *et al.*[5] The platelets were counted using a Neubaeur haemocytometer under a phase contrast microscope.

20 µl supernatant from sonicated platelet pellets in 0.1 ml of 0.4 M perchloric acid was injected into an HPLC system integrated with an electrochemical detector to determine the neurotransmitter contents. HPLC separation conditions were followed as previously reported[6]. The monoamine values were expressed per million platelets. 1.0 ml plasma was diluted in equal volume of distilled water. 50 µl of 5 mM sodium

Table 1. Blood glucose levels and body weight of experimental animals

	Blood glucose level (mg/dl)	Body weight (g)
Control *n* = 4	103.28 ± 3.76	174.58 ± 1.69
Diabetic *n* = 6	223.58 ± 20.79*	126.25 ± 4.37*

ND – not detected.

Values are mean ± S.D of 4–6 separate determinations.

bisulphite was added to it followed by 250 µl of 1 M Tris buffer pH 8.6. Acid alumina (20 mg) was then added, mixed for 20 min, the supernatant aspirated off and alumina was washed with 2.0 ml of sodium bisulphite. To the final pellet of alumina, 0.2 ml of 0.1N perchloric acid was added. The supernatant was filtered and used for HPLC determination of monoamines. 20 µl of extracted sample was injected into a Shimadzu HPLC apparatus connected to a C-18 reverse-phase column. The mobile phase consisted of 75 mM sodium phosphate monobasic, 1 mM sodium octyl sulphonate, 50 µM EDTA and 8% acetonitrile. The pH was adjusted to 3.25 with phosphoric acid and filtered through a Millipore filter. A flow rate of 1 ml/min was used. The monoamines were identified using electrochemical detector. The peaks were identified by relative retention time with standards and the contents were calculated using a Shimadzu integrator (Chromatopac CR6A) interfaced with the detector. Data were statistically analysed by Student's *t* test.

Blood glucose levels of all patients screened were significantly high ($P < 0.05$) compared with controls (diabetic 191.9 ± 7.6 mg/dl, controls 102.2 ± 5.3 mg/dl). Circulating plasma NE and EPI were increased ($P < 0.05$) in human samples. There was a significant increase ($P < 0.01$) in platelet NE, EPI and 5-HT content when compared to controls. The platelet count was significantly reduced ($P < 0.05$) in diabetic patients (Table 2).

Plasma NE and EPI content in experimental animals showed a significant increase ($P < 0.05$), but the increase in plasma NE of diabetic rats was less compared to humans. The EPI and 5-HT content of diabetic rat platelets showed a significant increase ($P < 0.01$). The insulin-treated group showed a decrease in platelet EPI content ($P < 0.01$) compared to diabetic untreated group. There was a significant reduction in platelet counts of diabetic rats ($P < 0.05$) compared to control. The insulin treatment to diabetic rats showed an increasing trend in platelet count but was not significant (Table 3).

The results of the present study showed a diabetic-induced change in the levels of platelet monoamines. In both humans and rats, the plasma NE and EPI levels were significantly high. A similar trend was seen in platelet NE and EPI content of human samples. The content in rat platelets was significantly high, while the NE content could not be detected. The increase in NE and EPI content of human platelets corresponded with the increase in plasma NE and EPI concentration. The same pattern was observed in rat model. But in diabetic rats the increase in plasma NE level was very low compared to human samples. This may be the reason for undetectable level of platelet NE in rats. The increase in plasma NE and EPI observed in experimental diabetes as well as human subjects may be due to the increased output of sympathetic stimulation in both these cases. Previous studies have shown the involvement of sympathetic nervous system in elevating plasma NE and EPI in diabetic condition. The adrenal glands may also be involved in bringing about an increase in EPI[7]. Martin *et al.*[8,9] reported increased serotonin content in human and rat platelet in diabetic condition. Acute myocardial infarction showed a similar platelet 5-HT content[10]. There are also reports of altered NE, EPI and 5-HT in brain regions of diabetic rat models as well as humans[11].

The present study showed a decrease in platelet number in diabetic patients as well as in rat models which supports our earlier report on decreased number of platelets in diabetic rats[12]. The increased content of neurotransmitters observed in plasma and platelets may be similar to the increased sympathetic stimulation observed in our previous studies in pyridoxine-deficient animal models[13]. The increase in monoamine uptake by the platelets can be due to alteration of platelet membrane potential[14]. Kjeldsen *et al.*[15] have reported that a depletion of sodium in the diet can increase the monoamine uptake by the platelets. It appears that the changes in rat and human samples of plasma monoamines are correspondingly reflected in the platelet monoamines. Thus it is suggested that the platelets can be used for measuring the levels of NE, EPI and 5-HT in diabetic condition and the platelet content of these neurotransmitters is altered in untreated diabetes.

A Mössbauer spectroscopic study of the Pipliya-1 meteorite

K. L. Shrivastava, R. P. Tripathi* and V. K. Vaya

Department of Geology and *Department of Physics, JNV University, Jodhpur 342 005, India

A recently fallen stony type meteorite in Rajasthan namely Pipliya-1 meteorite has been investigated using Mössbauer spectroscopy at 300 K. The obtained Mössbauer parameters resemble pigeonite to a greater extent, among pyroxene. The ratio of Fe^{2+} inner doublet and Fe^{2+} outer doublet confirm the textural interpretations of the geothermal history of the pyroxene. Presence of a weak Fe^{3+} doublet is probably indicating the change in the oxidation state of Fe^{2+} in the meteroite itself because of shock phenomenon.

THE Pipliya-1 meteorite is one of the two Pipliya meteor showers fallen on 20 June 1996 at 20.30 h at village Pipliya Kalan (Lat. 26°2'5": Long 73°56'30"), Pali, Rajasthan, India. A preliminary study of the same has been reported recently[1]. In this paper the Mössbauer spectroscopic study of the Pipliya-1 meteorite is reported.

The Pipliya-1 meteorite has a glossy pitch black crust of nearly 500 μm thickness. Under the fused crust it has typical characters of a stony meteorite. The rock as a whole is a complex breccia consisting chiefly of two types of fragments (type A and type B, welded together), and a few xenoliths[1]. Type A is a fine-grained, gray rock while type B is a coarse-grained, grayish-white rock as reported[1]. The thin sections under petrological microscope reveal[1] that type A is composed of grains of pyroxene (65%), plagioclase (25%), opaque minerals (6%), and some xenoliths (4%). Type B is composed of pyroxenes (55%), plagioclase (40%) and opaque minerals (5%). Pyroxene is clinopyroxene of pale pink colour, nonpleochroic with moderate extinction angles.

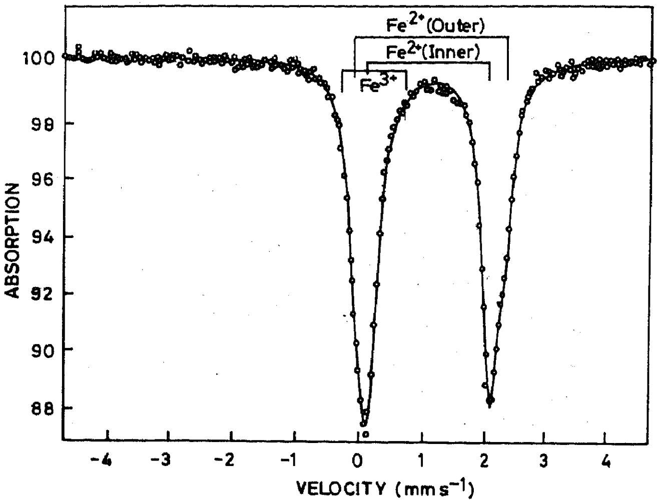

Figure 1. Mössbauer spectrum of rock type A of Pipliya-1 meteorite at 300 K.

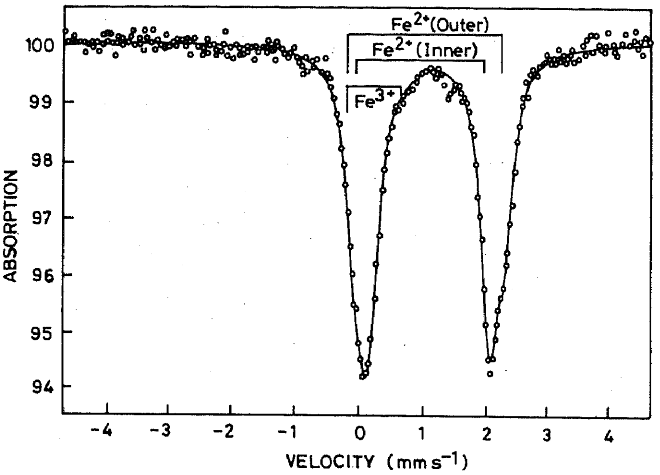

Figure 2. Mössbauer spectrum of rock type B of Pipliya-1 meteorite at 300 K.

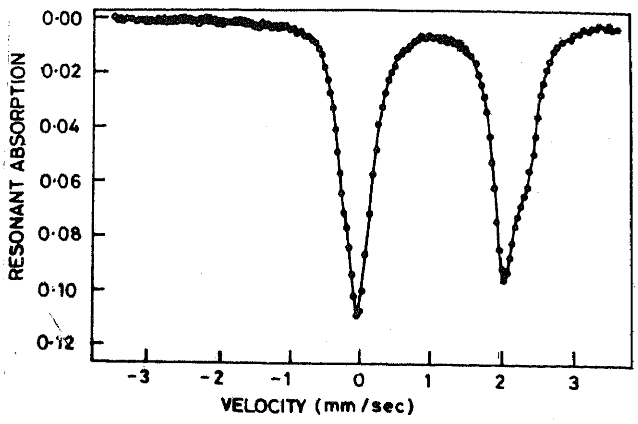

Figure 3. Resonant absorption spectrum of Fe^{57} (295 K) in pigeonite separated from a coarse-grained basalt of the Apollo 11 landing site at Mare Tranquillitatis (ref. 3).

The Mössbauer spectra for both type A and type B have been recorded at 300 K. The thin absorber was prepared by sandwiching fine powder in a sample holder of 2.5 cm diameter. A constant acceleration type Mössbauer spectrometer was used with 25 mCi, Co^{57} in Rh matrix source. All the spectra were computer fitted using a computer program given by Meerwal[2] with some modifications. This program assumes the spectrum to be the sum of Lorentzians. In the present study, the width and the intensity of the two halves of a quaderupole doublet were constrained to be equal. The various permutations and combinations were tried out and iterations were continued till minimum and acceptable χ^2 (goodness of fit parameter) was obtained. The solid lines in the spectra reported here, represent the computer-fitted curves and the dots are the experimental points. This IS (Isomer Shift) values are recorded with respect to the centroid of an α-iron foil. The positions of the individual doublets are marked on the spectrum.

Mössbauer spectrum of type A and type B rocks, constituting breccia of the Pipliya-1 meteorite is shown in Figure 1 and Figure 2. The Mössbauer parameters of the same are given in Table 1. The Mössbauer spectrum of a pigeonite sample obtained from a coarse-grained basalt of Appolo 11 landing site at Lunar is also given in Figure 3 for comparison[3]. The Mössbauer spectra of one terrestrial orthopyroxene (hypersthene) and one clinopyroxene (augite) are given in Figure 4 and Figure 5, respectively for comparison[4].

Several workers have reported the Mössbauer spectra of ortho and clino-pyroxenes[5–15]. The Mössbauer parameters of pyroxenes obtained by the earlier workers are presented in Table 2. In orthopyroxenes, the inner quadrupole doublet (which has smaller QS value) is attributed to Fe^{2+} in M2 site and outer quadrupole doublet is attributed to Fe^{2+} in the M1 site (which has larger QS value). On the other hand, the clinopyroxenes show their inner quadrupole doublet attributed to M1 site and the outer doublet to Fe^{2+} in M2 site. This is because in orthopyroxenes, the M2 site is more distorted than the M1 site, while in the clinopyroxenes M1 site is more distorted than the M2 site.

The Mössbauer spectra of Pipliya-1 meteorite samples show two intense quadrupole doublets but χ^2 values is significantly improved if a very weak doublet is also considered to be present in the fitting. The Mössbauer parameters for both the intense quadrupole doublets are characteristic of Fe^{2+} in high-spin state. On the other hand, a weak doublet indicates the presence of iron in Fe^{3+} state.

Table 1. Mössbauer parameters for Pipliya-1 meteorite at 300 K

Sample (meteorite)	Quadrupole split (QS) (mm s^{-1})	Isomer shift (IS) (mm s^{-1})	Line width (LW) (mm s^{-1})	Relative area (RA)	Doublet	$\frac{Fe^{2+}\ inner}{Fe^{2+}\ outer}$ (Ratio)	χ^2 (per 243 degree of freedom)
Rock type A	1.94	1.09	0.34	71.77	Fe^{2+} doublet (inner)		
	0.93	0.26	0.32	5.25	Fe^{3+} doublet	$\frac{71.77}{21.98} = 3.28$	1.36
	2.40	1.13	0.29	21.98	Fe^{2+} doublet (outer)		
Rock type B	1.92	1.09	0.37	68.01	Fe^{2+} doublet (inner)		
	1.05	0.26	0.27	4.54	Fe^{3+} doublet	$\frac{68.01}{27.45} = 2.47$	1.42
	2.39	1.12	0.32	27.45	Fe^{2+} doublet (outer)		

Table 2. Mössbauer parameters reported for the pyroxenes

Pyroxene	Outer doublet IS (mm s^{-1})	Outer doublet QS (mm s^{-1})	Inner doublet IS (mm s^{-1})	Inner doublet QS (mm s^{-1})	Reference and remarks
Diospside	1.15	2.95	1.15	2.06	Ref. 4 (average of two samples)
Orthopyroxenes	1.16	2.57	1.14	2.04	Ref. 7 (average of seven samples)
Hypersthene	1.15	3.00	1.15	2.14	Ref. 4 (average of two samples)
Pigeonite	1.15	2.5	1.15	2.0	Ref. 3 (calculated from spectra of one Lunar sample)
Augite	1.12	2.72	1.10	2.11	Ref. 4 (one sample)

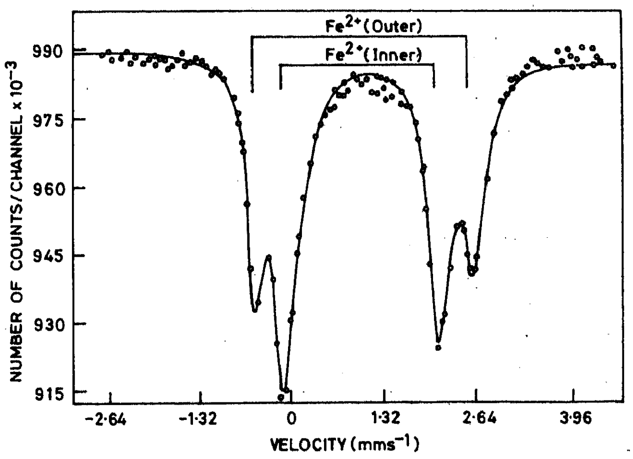

Figure 4. Mössbauer spectrum of terrestrial ordered hypersthene sample at 300 K (ref. 4).

The petrographic studies carried out earlier[1] indicated the presence of appreciable amount of clinopyroxenes in the Pipliya-1 meteorite samples. The Mössbauer parameters obtained in the present investigation (Table 1) also show those values which are characteristic of iron in clinopyroxenes. The large resonance absorption indicates the presence of higher concentration of iron in the sample, which is generally the case in pigeonite because it contains more $FeSiO_3$ component in solid solution. A comparison of the spectra obtained for the Pipliya-1 meteorite with the spectrum of Lunar sample[3] has been made. Both show pigeonite. Although there is no Fe^{3+} in Lunar basalt sample[3], both show similar line shape and Mössbauer parameters, which further strengthen the conclusion regarding the presence of pigeonite. Furthermore, Mössbauer parameters obtained presently (Table 1), do not tally with those reported for orthopyroxenes nor with those of other clinopyroxenes (Table 2).

As far as difference in the Mössbauer absorption in the meteorite samples is concerned, an observation can be made that the relative quantity of pyroxene is more in rock type A than rock type B. This observation is well within the limitation that the thickness of the absorbers for both the types was approximately the same,

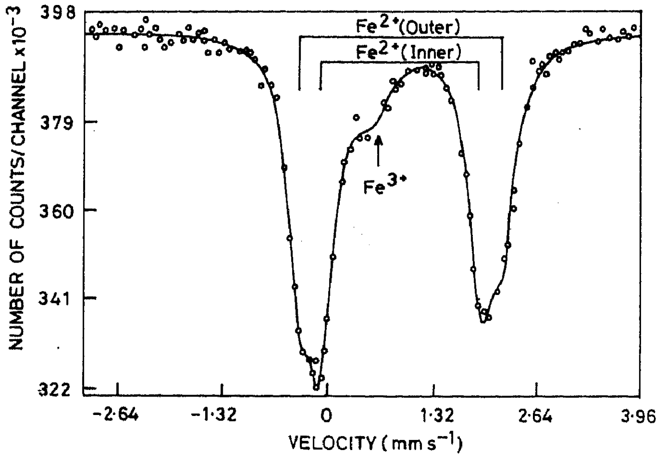

Figure 5. Mössbauer spectrum of terrestrial augite sample at 300 K (ref. 4).

assuming that the 'f-fraction' (recoil free fraction) for pyroxenes in both the types is the same (which is generally the case).

The ratio of Fe^{2+} inner/Fe^{2+} outer is dependent on the geothermal history of the pyroxene[16]. Table 1 shows that the Fe^{2+} inner/Fe^{2+} outer ratio for rock type A is 3.28 and for rock type B is 2.47. It shows that rock type B has more equilibrium distribution and must have undergone slow cooling in comparison with the fast cooling of the rock type A. The conclusion is in accordance with the interpretation in the text.

The fine-grained texture of rock type A is evidence of fast cooling in comparison with the medium-to coarse-grained texture of rock type B showing slow cooling.

A Fe^{3+} doublet of weak intensity has been fitted in the Mössbauer spectra. This peak could have been due to the change in the oxidation state of Fe^{2+} in the meteorite itself because of shock phenomenon. However, this assignment should be considered with caution because the intensity of the doublet is quite weak.

Altruistic behaviour in *Dictyostelium discoideum* explained on the basis of individual selection

Daniella Atzmony*, Amotz Zahavi* and Vidyanand Nanjundiah**

*Institute for Nature Conservation Research, Tel-Aviv University, Tel-Aviv 69978, Israel.

**Center for Ecological Sciences and Developmental Biology and Genetics Laboratory, Indian Institute of Science, Bangalore 560 012, India

It is often argued that natural selection acting at the level of the individual may not be sufficient to explain the evolution of altruism. We suggest that before accepting such a point of view in any specific instance, the parsimonious course would be to examine all possible ways in which individual-level selection might act and rule out its sufficiency only when the postulated means for its action are either inherently improbable or experimentally disproven. As an illustration we propose an evolutionary model, based on the individual cell as the unit of selection, for the maintenance of 'altruistic' behaviour by pre-stalk cells in the social amoeba *Dictyostelium discoideum*.

EVOLUTION by natural selection proceeds via the accumulation of successive adaptations that serve to increase the reproductive fitness of an individual measured over its lifetime. Obviously, traits that appear to be detrimental to the fitness of an individual but advantageous to another individual – or to a group – are difficult to reconcile with this view of natural selection. It has been proposed that in order to explain the existence of such traits, one may need to invoke the action of selection at the group, meaning supra-individual, level. Group selection can work in two ways. It may operate directly, between groups[1], or indirectly, within groups – thereby superficially resembling individual selection –, when the groups contain individuals with a significant degree of genetic relatedness. In the latter situation, known as kin selection, kinship makes it possible for the fitness of either of two interacting individuals to be greater than that of the same individual in the absence of interaction[2]. This is because kinship leads to an increase in the probability that both of them carry copies of one or more genes for promoting altruism that are identical by descent. Thus, although an individual may choose to reduce the number of offspring that it has, it may nevertheless benefit genetically if it thereby enhances the reproductive fitness of the second individual to a sufficient extent. Here 'sufficient' means that after devaluing for the coefficient of genetic relatedness, the first individual leaves behind more copies of its genes (albeit indirectly) than it would otherwise. Then, the frequency of an 'altruistic' gene can increase in time and the gene can spread through the population. Indeed, it is often held that such a gene's eye-view is the correct way to think of all evolutionary adaptations, whether in solitary organisms or in social groups[3]. In an extreme situation the first individual may forego reproducing entirely and yet the trait may persist successfully through generations.

Although sound in principle, the concepts of group selection and kin selection have problems in practice[4,5]. Group selection involving non-kin demands special population structures that may not always exist, and explanations based on kin selection can flounder if genetic relatedness is not as high as is demanded by theory[6]. Besides, both models, as well as those based on 'reciprocal altruism'[7], are potentially unstable[8]: they are susceptible to exploitation by 'cheaters', individuals whose contribution to the group is in some sense lower than the benefits they derive from the group. Therefore groups also need to possess the ability to detect cheaters and nullify their effect. The inherent instability of group selection (in which term we also include kin selection) makes it a matter of paramount importance to push arguments based on individual-level selection to their logical conclusion. Except when it can be shown to be inherently improbable or experimentally disproven, such an undertaking has two merits. One, it forces us to think of all possible routes whereby the expected lifetime reproductive success of an individual might be enhanced. And two, it opens up a far richer picture of the evolutionary process for subsequent analysis and testing than a group-selection explanation does; see ref. 9 for an example. We now develop this thesis for the case of division of labour in *D. discoideum*.

But before doing so, it might help to reiterate the essential operational differences between the various models for the evolution of sociality listed above. These differences pertain to the calculation of fitness. For illustrative purposes, let us imagine that we are dealing with a pair of interacting individuals at a time and are comparing expected values of lifetime fitnesses between two situations, one in which cooperation (apparent altruism) is exhibited and the other in which it is not. In a group selection model the average fitness of the pair increases by virtue of altruism. Reciprocal altruism guarantees that each individual gains by cooperation, but only if reciprocity is assured. With kin selection each member of the pair benefits by cooperation because it shares genes with the other (the relevant measure of fitness being inclusive fitness). And under all three schemes a prospective cheater gains most of all unless appropriate counter-measures are implemented. On the other hand, in an individual selection model the only relevant parameter is the intrinsic phenotype of the individual. Given differences in phenotype, reproductive fitnesses will also differ. There is no question of a cheater exploiting the situation because a prospective cheater will also have to take its place, so to speak, in the phenotypic hierarchy – which is equivalent to a fitness hierarchy.

The Dictyostelid slime molds, of which *Dictyostelium discoideum* is the best-studied species, are among the most primitive examples of social organization[10]. Unicellular amoebae aggregate to form a colony within which division of labour takes an extreme form: one subset of amoebae dies and forms a rigid, upright stalk and the other subset forms a ball of spores above the stalk[11]. By making use of a variety of criteria based on staining with vital dyes[11], fluorescence-activated cell sorting[12] and patterns of gene expression[13] it is possible to distinguish between pre-stalk and pre-spore amoebae. Also, the two presumptive cell types are spatially segregated: in the migratory, slug-shaped stage of development that the aggregation goes through, pre-stalk cells occupy approximately the anterior fifth and pre-spore amoebae the posterior four-fifths[14].

After differentiating into spores, pre-spore amoebae come to lie on top of the stalk, meaning at a height above the level of the substratum. It seems reasonable to assume that spore fitness is enhanced thereby, because elevation should improve the chances of successful spore dispersal. On all grounds the pre-spore strategy makes obvious reproductive sense. On the contrary pre-stalk amoebae appear to exhibit altruistic behaviour because in the course of improving the chances of spore dispersal and so increasing the fitness of pre-spore amoebae, their own direct reproductive fitness is reduced to zero. It has been questioned whether such altruistic traits can be accounted for on the basis of individual-level selection (see, for example, ref. 15).

Previous attempts to explain the evolution of sociality in the cellular slime molds have made use, either implicitly or explicitly, of group selection or kin selection arguments[16–19] or have used Evolutionarily Stable Strategy-based reasoning[20] that gives rise to a situation that is also unstable with respect to exploitation by cheaters. There is one experiment that seems to favour kin selection in *D. discoideum*[21], but aspects of its methodology make interpretation somewhat difficult: the authors take the ratio of sorus diameter to stalk height as a measure of the ratio of spore to stalk numbers, and this may not be a good approximation when the stalk is more than one cell thick. In contrast to these earlier models, we now proceed to argue in favour of the proposal that the seemingly suicidal behaviour of pre-stalk amoebae may have a conventional, Darwinian (meaning, individual selection-based) explanation. Under laboratory conditions, *Dictyostelium* aggregations are commonly clonal; but the average degree of relatedness within aggregations in the wild is unknown. Therefore, quite apart from the fact that a high degree of genetic relatedness *per se* would not argue against individual-level selection, the relevance of kin selection in the wild remains a moot question. However, as will be made evident, the reasoning that we use remains valid irrespective of the degree of kinship.

Dictyostelium amoebae emerge from spores, go through a phase of feeding and cell division via mitosis, and proceed to aggregate once the local food supply is exhausted[11]. Our central assumption is that at the time of aggregation there are cell-to-cell variations in phenotypic quality. By quality we mean a parameter that is related to individual fitness; for example, quality may be measurable in terms of the level of metabolizable sugars accumulated by a cell during feeding[22,23]. Quality is, firstly, a relative measure. Secondly, it varies from one cell to another in a quasi-continuous manner. However, for the sake of simplicity we assume that cellular quality can have just two (relative) values. Thus there are high quality (HQ) and low quality (LQ) cells. Our basic contention is that phenotypic selection will ensure that HQ cells stand a high chance of sporulating whereas LQ cells have a low chance of doing likewise. It is evident that such an outcome is intrinsically stable. Genetic differences need not come into the picture at all: obviously, quality may have a genetic component, but as far as the theory goes the cells could be genetically identical. We point out that there is experimental support for a functional non-equivalence between pre-aggregation amoebae as assumed here[12].

A second assumption is that amoebae can assess each other's quality by means of intercellular signals. Signalling may either precede aggregation (for example, via Conditioned Medium Factor, CMF; ref. 24) or follow aggregation (for example, via cyclic AMP; ref. 25 or via Differentiation Inducing Factor, DIF; ref. 26). HQ cells proceed to differentiate along the pre-spore pathway and also attempt to coerce LQ cells to adopting the pre-stalk pathway. The metabolite DIF may be an agent of coercion (see below). The options open to LQ cells are severely restricted. They can choose to stay out of the aggregate and remain solitary, but if they do so they are certain to die[27]. Alternatively, they can join the aggregate and cooperate with pre-spore cells to begin with, all the while exploring opportunities to escape what appears to be their fate and survive, perhaps eventually sporulate. The probability of succeeding in the enterprise is small but not zero: there is evidence that spores can arise from amoebae in which pre-stalk-specific genes were previously expressed[28]. Also, undifferentiated amoebae have been reported in the spore mass and may be a second kind of 'escaper' pre-stalk cells[29,30]. In any event, LQ cells will favour the pre-stalk option even when by doing so their chances of survival are infinitesimal, because the other option – not to aggregate – results in certain death.

DIF (a doubly chlorinated hexanone; ref. 31) and closely related compounds with similar effects are produced by amoebae after aggregation and act as cellular poisons[32]. In low-density assays they cause cells to die and become stalk-like[33]. Curiously, while it is the pre-stalk cells that die and pre-spore cells that give rise to the next generation, the level of DIF is higher in pre-spore cells than in pre-stalk cells[34]. In terms of physiology, the reason behind this is that pre-stalk cells make an enzyme, DIF dechlorinase, that breaks down DIF[26]. But in terms of group (or kin) selection, this does not make sense. Why should pre-stalk cells actively lower the level of a metabolite that is pushing them further, as it were, along the pathway of altruism? On the other hand, individual level selection would suggest that pre-stalk cells (being of relatively lower quality) are inherently more susceptible to DIF than pre-spore cells. Therefore, whereas pre-spore cells are able to continue on the pre-spore pathway in the face of a high local concentration of DIF, pre-stalk cells need to take active steps to break it down in order to prevent early death. Loomis[36] and we[30] have discussed models for pattern formation involving intercellular interaction based on assumptions similar to the ones made here (in particular, Loomis suggests that pre-spore cells may be more resistant to DIF than pre-stalk cells). Recent evidence indicates that there is a heterogeneity even within the pre-spore class; only some pre-spore amoebae exhibit a transient shift to the pre-stalk class (in the sense that their level of intracellular calcium increases) upon stimulation by DIF[35].

A number of testable inferences follow from our model. The existence of a cell-to-cell variation in quality can be tested by sorting presumptive stalk and spore cells at the pre-aggregative stage and probing individuals from each class in respect of fitness-related variables. If the (internal) nutritional reserve available when (external) food supply runs out is a measure of cellular quality, and if DIF plays the role that we suggest it does, one would expect that there is both a higher level of DIF, as well as a greater resistance to DIF, in amoebae grown on a rich medium when compared to amoebae grown on a poor medium. Finally, if DIF acts like an intercellular poison, as it appears to, the operation of individual-level selection would imply that its use as a poison must be a side effect. The primary reason why DIF is made by individual cells would be for their own direct benefit. For, suppose the sole use of DIF was as an agent of coercion against other cells. In that case it would be a metabolic saving, and so of selective advantage, to a pre-spore cell to derive the benefit of the DIF made by other pre-spore cells but to make none itself. Thus a putative 'cheater' prĕ-spore cell that derived the benefits of the DIF made by many other pre-spore cells, but made none itself, would be selectively favoured over the rest. Of what direct benefit might DIF be? One possibility is that DIF protects individual amoeboe or spore cells from microbial attack. It would be worthwhile to look for the presence of DIF in spores. These experiments are currently underway.

In conclusion, we point out that *D. discoideum* by no means exhausts the enormous range of developmental strategies that are seen in the Dictyostelids and their relatives[10,16]. There are species in which a single amoeba can sporulate, species in which the stalk is an extracellular product and species in which cells die and produce a stalk continuously during the course of migration. A careful and detailed study of each case will be needed before we can similarly attempt to explain its evolutionary origins on the basis of individual-level selection.

Possible evidences of animal life in Neoproterozoic Deoban microfossil assemblage, Garhwal Lesser Himalaya, Uttar Pradesh

Purnima Srivastava and S. Kumar

Department of Geology, Lucknow University, Lucknow 226 007, India

An exceptionally well-preserved microfossil assemblage comprising bacteria, cyanobacteria, algae, fungi, acritarchs and forms exhibiting rather complex/unusual morphology from the black-bedded chert of the Deoban Formation (Garhwal Lesser Himalaya) points to a complex ecosystem of the Neoproterozoic times. The Deoban assemblage is interpreted to have been preserved in the algal-mat facies. Of special interest in this context is the discovery of three problematic forms of questionable affinity. These are comparable to the members of Nematoda and Annelida phyla of the animal kingdom. This suggests that the advent of heterotrophy among animals in its incipient form started in Neoproterozoic which ultimately facilitated the evolution of more complex and advanced communities of multicellular organization in later geological times.

THE late Proterozoic life is represented by Ediacaran soft-bodied animals, acritarchs, prokaryotes, eukaryotes, trace fossils and stromatolites. In recent years many commendable efforts have been made to document the rich fossil records from different parts of the globe which have made the Proterozoic history of life quite impressive and informative. Though the records of plant fossils representing the ancient ecosystem are many[1–6], those dealing with the animal life in the Proterozoic are very few[7–9] and lack the firm basis for assignments of affinities. But during this eon animals must have evolved which ultimately gave rise to well-diversified fauna at the beginning of Cambrian.

The present paper documents three forms from the Deoban Formation of Lesser Himalaya, seen in random thin sections of black-bedded cherts associated with dolostones, which possibly represent the animal organization. Of these, two forms are comparable to some extent with living worms belonging to invertebrate phyla Annelida and Nematoda respectively and the third one is compared with a back-filled burrow. They occur in association with a diversified microfossil assemblage undoubtedly assignable to plant kingdom. The assemblage in general is dominated by benthic population of cyanobacteria, referable to *Siphonophycus*, *Myxococcoides* and *Eoentophysalis*[10–12].

The Deoban Formation is ca. 1000 m thick carbonate sequence ideally exposed near Deoban Hill in the Chakrata area of Dehradun district. The Deoban Formation overlies the Simla Slates possibly with a thrusted contact and is overlain by the Mandhali Formation (Figures 1, 2). The fossiliferous chert samples have been collected from the Deoban Forest Rest House–Chakrata mule track. The lithology is represented by micritic dolostone with intercalations of shale, oolitic dolostone and stromatolite-bearing horizons. These

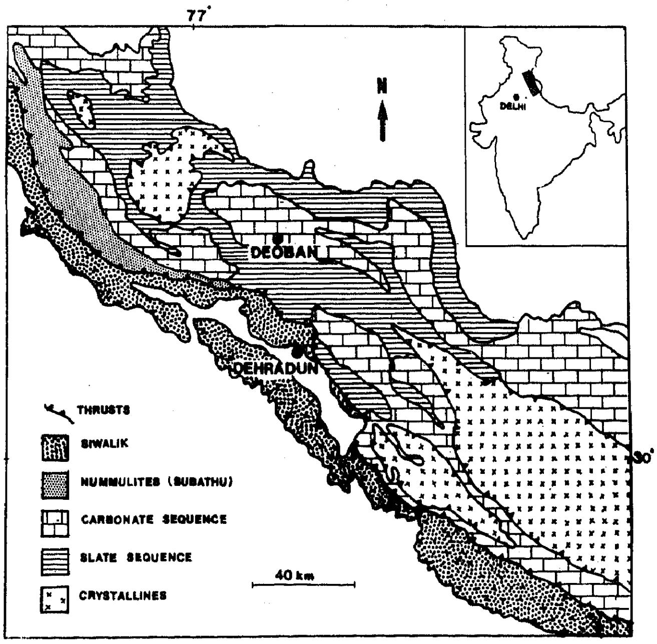

Figure 1. Location and geological map of Garhwal region of Uttar Pradesh (Simplified after ref. 23).

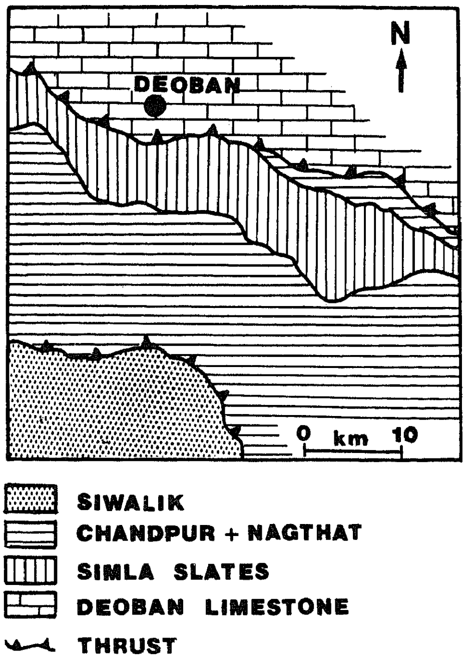

Figure 2. Geological map showing distribution of stratigraphic units in the Chakrata area, Garhwal Himalaya, India (after ref. 15).

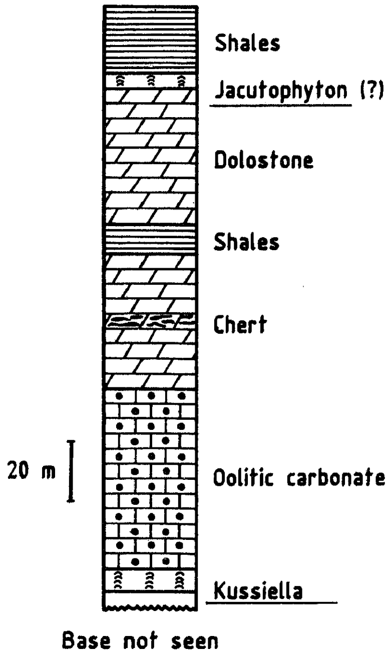

Figure 3. Position of fossiliferous chert in the litholog of the Deoban formation.

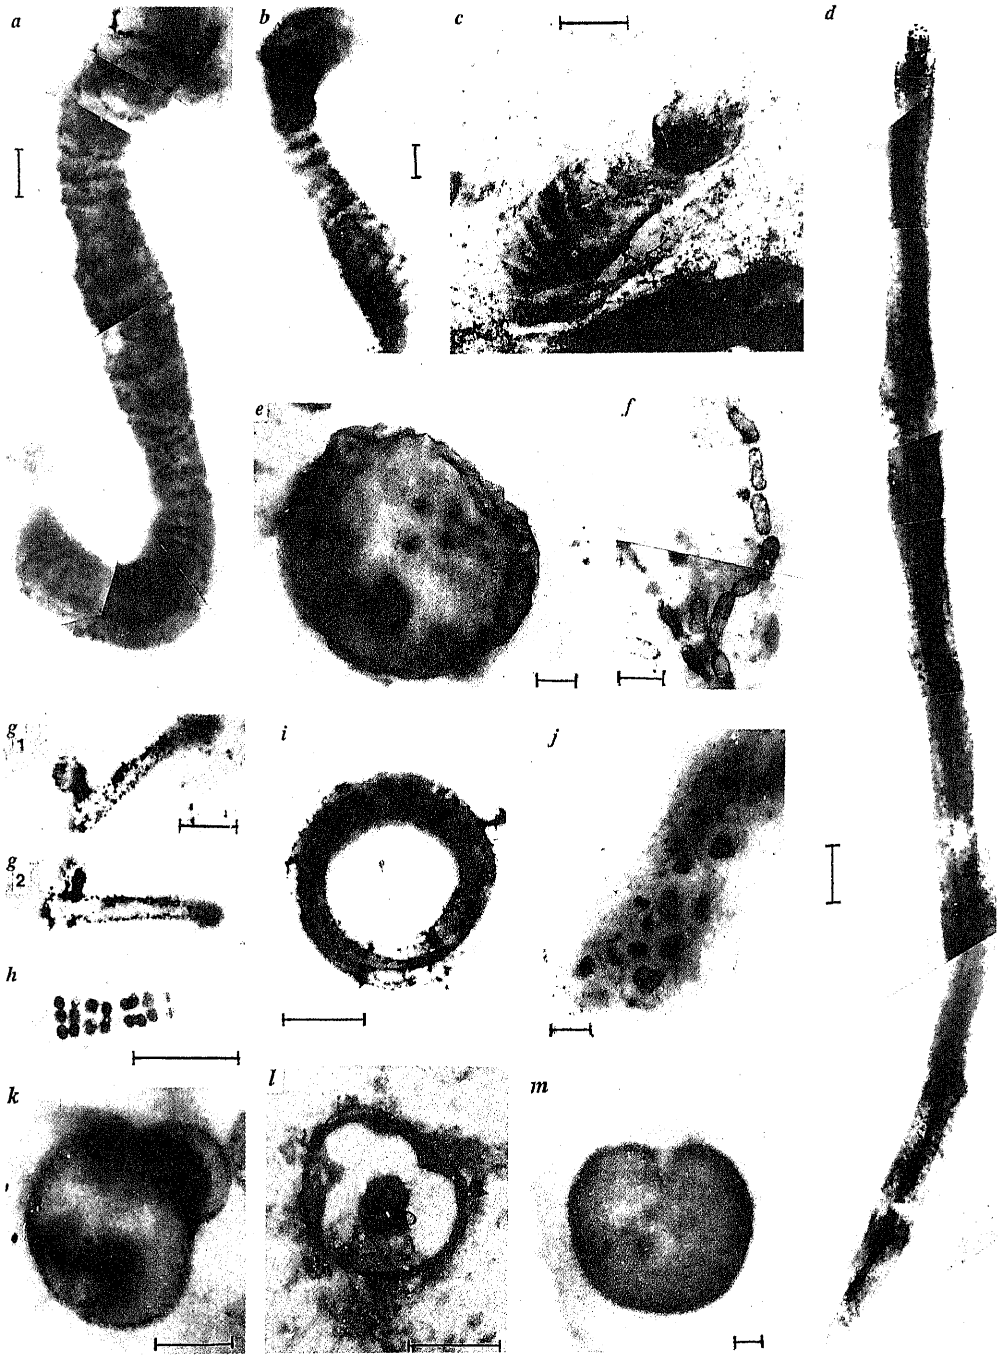

Figure 4. Microfossils from the Deoban Formation, India. All the photomicrographs are from petrographic thin sections of chert housed in Museum of Department of Geology, Lucknow University, Lucknow. Scale bar in all figures represents 10 μm except for the *c* and *l* where it represents 100 μm. ***a–b***, Partitioned worm-like structure, constricted at partitions; ***c***, Back-filled burrow or a microstromatolite-like structure preserved in chert; ***d***, Nonseptate, long, tubular body (comparable to worm of Nematodean affinity) tapered at posterior end. Gut-like tubular structure is seen running throughout its length and projected median part (at the anterior end) and back shifted side margins are also seen; ***e***, Folded walled acritarch; ***f***, Coccus/bacillus bacterial structures arranged in a row; g_1–g_2, Bud-like structure comparable to fungal budding. ***h***, Cyanobacterial or algae-like structures; ***i***, Spirally coiled form (*Obruchevella* sp.) in cross-sectional view where 3–4 whorls are seen. ***j***, Typical arrangement of cells (as in Chlorophyceae); ***k***, Fungal budding (?); ***l***, Sphaeromorph (*Trachysphaeridium* like acritarch); ***m***, Spherical body with 'V' shaped opening.

bands, nodules and lenticles of fossiliferous black chert occur within the carbonates. The position of fossiliferous chert is marked on the lithological column (Figure 3). The chert horizon lies between the two stromatolite-bearing units. The overlying unit contains stromatolite *Jacutophyton* (?) and the underlying unit is characterized by *Kussiella*[13].

The Deoban microfossil assemblage represents a very complex and advanced ecosystem[11,12]. In general the assemblage is dominated by coccoid and filamentous forms of cyanobacterial affinity, though the presence of algal, fungal, bacterial and acritarch forms has also been noticed. Micron-sized coccus and bacillus forms are the smallest forms (1–2 μm) of bacterial affinity (Figure 4*f*). The occurrence of structures comparable to fungal hyphae, bud-like structures (Figure 4 g_1, g_2), typical cellular organization characteristic of chlorophycean forms (Figure 4 *h*, *j*) and large-sized organic walled acritarchs (Figure 4 *e*, *l*) strongly support the presence of eukaryotes among the Deoban microfossil assemblage. In addition, the biostratigraphically significant cyanobacterial form *Obruchevella*[14] (Figure 4 *i*) adds to the complexity of this ecosystem.

In absence of radiometric dates there is no general agreement regarding the age of the Deoban Formation. The age has been suggested from Lower Riphean to Lower Cambrian[13,15]. On the basis of microfossil assemblage especially the presence of *Obruchevella*, large-sized acritarchs and absence of megafossils including trace fossils and noticeable absence of typical Vendian forms (well developed acanthomorphs), the age of the Deoban Formation should be pre-Vandian, i.e. Upper Riphean.

The morphological details of the three problematic forms are: An annulated sinuous and septate filamentous body which is slightly constricted at septa (Figure 4 *a*, *b*). The diameter is almost uniform (10–12 μm) throughout the length except at the ends, which show marked increase in diameter (14–15 μm, 3 specimens traced). The maximum length measured is 280 μm. An elongated tube-like structure running parallel to outer margins is seen in one specimen.

The morphology of these specimens partly resembles Oscillatoriacean filaments (a number of easily identifiable oscillatoriacean specimens present in the Deoban assemblage), but can be differentiated by presence of marked sinuous architecture, broader terminals and annulation. These features make their comparison difficult with any of the extant plant groups and opens an option to compare them with miniatured extant worms belonging to the invertebrate phyla Annelida (Coelomate) or members of the phylum Nematoda known as *Desmoscolex* and *Epsilonema*[8,16,17]. *Rectia costata*[18], a Precambrian fossil from Russia also shows some resemblance with the present form. A megascopic worm-like metazoan (?) fossil named as *Pararenicola huaiyuanensis*[19] from an Upper Sinian Formation of China also shows a comparable morphology (except the dimensions).

A single specimen (Figure 4 *d*) showing a nonseptate tubular, unornamented body tapering at one end (with almost uniform diameter: 10–11 μm) is seen. The other end, probably the anterior one shows a prominently projecting median tube with slightly backshifted side margins. Length measured is 360 μm (single specimen traced).

Eomycetopsis (*siberiensis* sp.)[20], now merged into *Siphonophycus*[2, 21] can be compared with this specimen in diameter and nonseptate tubular body. However, the presence of projected median tube (which continues throughout its length) at one end of the body and tapering at the opposite end differentiates the Deoban specimen from the *Siphonophycus*. These features while supporting its independent entity, indicate some resemblance to *Echinotheristus*; which is placed under the phylum Nematoda[16]. Its projected end can be interpreted as the anterior part comprising mouth and tapered end as the posterior end representing the anal region. The median tube might be its gut as in the case of extant forms.

Living nematodes are usually millimeter sized but can be of microscopic dimensions also. They can be parasitic or nonparasitic in nature. Nonparasitic nematodes are benthic animals and live in interstitial spaces of algal mats, especially the aquatic sediments and soil[16]. This general habitat and mode of occurrence are the additional parameters that support the animal nature of this specimen (Figure 4 *d*) as the Deoban microfossil assemblage is interpreted to have flourished in an algal mat facies[11,12]. The Deoban chert shows presence of well-developed algal laminites comprising abundantly mat building populations; coccoides and filaments.

A single specimen exhibiting semicircular, multilamellate structure where lamellae are curved and each embraces the other. Diameter ranges between 130 and 170 μm, length measured is 380 μm (single specimen traced, Figure 4 *c*).

This particular form shows some resemblance to a cyanobacterial fossil form *Polybessurus*[22] and laminated constrictional features like microstromatolites. The present form can be differentiated from *Polybessurus* by the absence of cone-like structure. To some extent the morphology does favour its assignment to a back-filled burrow[8]: an animal trace-like structure (produced by some worm-like meiofaunal animal that peristaltically moved through sediment) or a microstromatolite.

If these rare and morphologically unusual forms are accepted as animal fossils, they will certainly enhance the significance and complexity of Deoban's ecosystem prevailing at the time of its sedimentation. Despite the controversy about the precise age, an exceptionally well-preserved, highly diversified assemblage of the Deoban microfossils may certainly provide a unique insight into the early stages of animal evolution. It appears that stromatolite-building microbial mat communities played an important role in the evolutionary processes.

The presence of animal life is important as it bears on the viability of the Deoban ecosystem in sustaining the relatively complex producer herbivore (heterotrophs) dominated food chains. This is in contrast to the earlier simple producer food chain based ecosystem that had dominated the global scene for hundreds of millions of years. Once established, the heterotrophy (among animals) may have accelerated the pace of evolution of a still complicated living system that gave rise to complex and more advanced multicellular animal organization in the Late Proterozoic times.

Ecology and Equity. The Use and Abuse of Nature in Contemporary India. M. Gadgil and R. Guha. Penguin India, 56, Nehru Place, New Delhi 110 019. Price: Rs 135. 213 pp.

At a time when environmental concerns are viewed with distrust and contempt by the policy makers, Madhav Gadgil and Ramachandra Guha's book *Ecology and Equity* comes to us like a whiff of fresh air. There is a lack of proper social scientific analysis on environmental problems in India – more so of any plausible solutions. The authors fill this vacuum by building up an analysis on empirical evidence and when they offer solutions the reader cannot but agree with them.

In this book we come face to face with the real India – the miseries faced by the ecological refugees and the impenetrable iron triangle of beneficiaries, administrators and decision makers.

The real beneficiaries of economic development are only one sixth of the population who are the omnivores. They are rich and powerful. On the other hand, the ecosystem people or the 'biosphere-people' are dependent on nature and hence very close to it. The ecological refugees are large in number and are those people who have been overlooked during the process of large-scale 'development projects'. The authors point out that while there could be no environmental movement which is totally opposed to economic development, for, that would isolate our country on the world map, the appropriate solution would be to integrate and blend conflicting objectives of economic growth and environment protection at every step.

In the first part of the book the authors delve into the past and trace environmental degradation to the colonial days when the British wanted to retain India as a colony purely for economic reasons, namely for its raw materials. As a consequence of breakdown of traditional land and water management practices, there has been a progressive degradation of our coasts, inland water, forests, grazing lands and farmlands. This section is very informative but at times makes repetitive reading. And for scholars familiar with the history of preindependent India, there is nothing new.

The most interesting theme is, however, the classification of the Indian population by the use of resources as governed by the iron-triangle of beneficiaries, administrators and decision makers. State subsidies have given rise to this state of affairs and the omnivores of the iron-triangle are adopting a method of exhaustive resource use at the expense of the ecological refugees and ecosystem people.

That the state machinery has failed abysmally in its performance is evident to everyone, but Gadgil and Guha do not stop there. This seemingly unassuming book is as full of data and information as it is of rhetoric. The second part of the book deals with the 'India that might be' where the authors start with the three main prevalent streams of ideologies namely Gandhism, the Marxist's utopia and the capitalist dream. Gadgil and Guha argue that neither Gandhism nor Marxist philosophy nor capitalism alone can cure the ills of our society. The blend of all the three has been called conservative–democratic–socialism. The emphasis on strong local community from the Gandhian tradition, the democratic institution and private enterprise from liberal capitalism and equity from Marxism have synthesized this conservative–liberal–socialism which is the answer to push India towards better growth and development. With effective decentralization and empowerment of the local people, this could be a solution.

In a country full of contrasts as the authors quote Vikram Seth:

> . . .
> And why is it that Minister's Hill
> And Babu's Barrow drink their fill
> Through every season, dry or wet,
> When all the common people get
> Is water on alternate days?

This book makes a realistic and frank assessment. A truly well written book – a must for every planner and the environment conscious.

Electrochemistry: The spreading reach of biology

Bioelectrochemistry of Biomacromolecules. G. Lenaz and G. Milazzo, eds. Birkhauser Verlag AG, PO Box 133, CH-4010, Basel, Switzerland. Price: SFR 198.

Biology has intruded into many areas of physics and chemistry and a whole host of subdisciplines now carry the prefix 'bio'. This ubiquitous prefix is found twice in the title of this book which is devoted to the 'bioelectrochemistry' of 'biomacromolecules'. This is the fifth volume in a series entitled 'Bioelectrochemistry: Principles and Practice'. Originally conceived as a comprehensive treatise on bioelectrochemistry by Giulio Milazzo, these volumes have undergone a transformation to a series of multiauthor volumes after his untimely death in 1993.

Electrochemistry has its origins in biology with the work of Galvani and Volta as the forerunner of much of modern day electrochemical research. This volume begins with two comprehensive chapters on the structures of nucleic acids and proteins which form almost half the book (182 pages). Here electrochemistry remains very much in the background. The chapter by Brabec, kleinwächter and Vetterl on nucleic acids is notable for its comprehensive treatment of the electrical properties of these polyanions. The discussion on the behaviour of DNA in electric fields and the dielectric properties of DNA may be useful to readers who normally have recourse only to conventional biochemistry texts, which place overwhelming emphasis on molecular structure and biochemical properties.

The article by Dan Urry on proteins is largely based on the author's own, seminal work on polypeptides, related to the fibrous protein elastin. This chapter makes fascinating reading and much of what is said here may in fact be unfamiliar to those conditioned to discussions of folding based on crystal structures of globular proteins. Although, early structural concepts in this field developed from studies of insoluble, fibrous proteins like collagen, keratin and elastin (and of course synthetic polypeptides), the later flood of information on globular structures has submerged most early work. I found the discussion of hydrophobic interactions and temperature effects illuminating. Urry highlights the marvelous process of 'crystallization upon heating' found in a cyclododecapeptide of elastin. The phenomenon of self assembly into more ordered structures on raising the temperature is indeed well known in the connective tissue proteins. The 'boiled egg' is of course a common everyday example. In more recent times, 'cold denaturation' of proteins has become a fashionable subject for study. This is 'of course the same reversible molecular process' as the heat induced ordering, as pointed out by Urry.

This chapter provides a fascinating extension to mechanochemical effects and electromechanical transduction, with dramatic examples of hydrophobicity-induced pK_a shifts. Which student of biochemistry would not be surprised to hear that it is possible to change the pK_a of an aspartic acid sidechain carboxyl by 6 units (a million fold change in acidity!).

Electrochemistry in its formal form finally appears in two chapters on redox proteins (Hill, Moore and Nabi Rahni) and applications of voltammetric methods (Armstrong). Finally we see cyclic voltammograms, the unmistakable sign that biology is giving way to electrochemistry. This section is instructive for its discussion of methodology and also for the range of applications (Fe–S clusters, proto-linked electron transfer and electron transfer in reductases and dehydrogenases). For the non-specialist reader there is a useful section on the glucose biosensor, now available as a 'glucose pen' for diabetics anxiously following their own sugar levels.

Sulphur is the most oxidizable element commonly found in proteins. Thiol-disulphide chemistry is central to life, as comprehensively reviewed by Gilbert. There is a wealth of information here which is not commonly found in other reviews of the area, particularly redox potentials in diverse proteins. There is yet another chapter on iron-sulphur proteins (Feinberg and Ryan) with a little overlap to earlier sections. The concluding chapter on glycosamino glycans (Pye) appears strangely out of place. While these are undoubtedly changed, the connection to the theme of the book is not readily apparent.

In summary, this is a readable book with many nuggets of useful information. The reference lists are slightly dated and the index is not very helpful. This volume must find a place in libraries that count electrochemists and biochemists amongst their clientele.

P. BALARAM

Molecular Biophysics Unit,
Indian Institute of Science,
Bangalore 560 012, India

COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH
(CSIR), NEW DELHI, INDIA

ADVERTISEMENT NO. 17/96

Position: Director, Central Salt & Marine Chemicals Research Institute (CS&MCRI), Bhavnagar (Gujarat).

CSIR, a premier agency established by the Govt. of India to undertake scientific and industrial research in the country, is looking for a suitable scientist/technologist for the post of Director for its Central Salt & Marine Chemicals Research Institute (CS&MCRI), Bhavnagar. The Institute is devoted to carrying out research and development work in the fields of salt, marine and other allied inorganic chemicals; to developing technologies for the desalination of brackish and sea water; to carrying out survey and promoting cultivation and utilization of marine algae and promoting exploitation of coastal dune sand and saline soils through introduction and cultivation of indigenous and exotic plants of industrial value. The major R&D programmes of the Institute relate to salt and salt engineering, marine chemicals, desalination of brackish/saline water, ion-exchange resins and polymers, reverse osmosis, marine algae, inorganic chemicals, photoinorganic chemistry and phytosalinity. The Institute also conducts short-term training courses in the areas of its specialization and takes up consultancy work especially in the areas related to salt production and desalination of water. The Institute has two field stations at Mandapam (Tamil Nadu) and Berhampur (Orissa).

The post carries the pay scale of Rs. 5900–200–7300 plus allowances as admissible to Central Govt. officials. The appointment to the post will be on contract for a period of six years or superannuation, whichever is earlier.

For further details, please contact the Director-General, CSIR, Rafi Marg, New Delhi 110 001, India, Fax: 3710618, Telex: 031–65202 CSIR IN, 031–66147 CSIR IN, Gram: CONSEARCH, NEW DELHI.

Interested candidates may send their complete biodata by **25 February 1997** to the Director-General, CSIR, Rafi Marg, New Delhi 110 001.

POSTDOCTORAL RESEARCH PROGRAMME IN LIFE SCIENCES AND BIOTECHNOLOGY
INDIAN INSTITUTE OF SCIENCE, BANGALORE

(A Programme sponsored by the Department of Biotechnology, Government of India)

Postdoctoral Research Associateships (approx. 10 positions) are available for bright young scientists to work in the frontier areas of modern biology at different departments of the Biological Sciences Division of the Institute. The Associateship is purely temporary and is tenable for a maximum period of 2 years starting from 1 April 1997. The award is given initially for a period of one year and is renewable for the second year on satisfactory performance.

Candidates holding Ph D degree in any branch of Life Sciences/Chemistry/Physics or M D and a uniformly good academic background are eligible for selection. Candidates who have already submitted the Ph D thesis but are awaiting the formal award of the degree are also eligible to apply, but they will be appointed as Research Associates (Provisional) till they obtain the degree. Minimum consolidated emoluments of Research Associates will vary from Rs 4000 to Rs 4500 p.m. Single room accommodation will be provided in the hostel for the selected candidates.

Candidates may apply on plain paper with biodata, list of publications (include reprints of important papers published), copies of degree certificates (B Sc, M Sc, Ph D), brief one-page synopsis of Ph D thesis, 2 letters of references (academic) and a declaration by the candidate stating that in case selected for the associateship, he/she will complete the 2 year tenure of the programme. The interviews for the associateships will be held in IISc by second/third week of March 1997.

Applications should be addressed to **Prof. K. P. Gopinathan, Chairman, Microbiology and Cell Biology Department, Indian Institute of Science, Bangalore 560 012**, to reach him before the end of February 1997, and should be clearly marked on the envelope as **DBT Post-Doctoral Associateship**.

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine. G., in *Biology of Bats* (ed. Wimsatt. W. A), Academic Press, New York. 1970. vol 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

How much water does a tree drink?

The futuristic Hollywood movie 'Water World' depicts a state of world where due to melting of ice caps, our earth is over-inundated with water and the dearest thing on earth for which humankind fights is not gold but soil mined from under water. Fortunately or unfortunately, such a scenario, if it arrives at all, is very far ahead and ahead enough that we need not worry now. On the contrary, among the major resources, what is immediately valued, after the liquid gold, is not soil but water. Our water tables are dipping, water sources are dwindling and despite two thirds of world being covered with water there are scary predictions that water scarcity might catalyse the escalation of inter-human conflicts. (Are we not already witnessing them between our states and with our neighbouring countries?)

Obviously the concern has been about the type of trees we are planting in our living habitats. What if a tree planted in an area consumes more water than the rains received there? We are probably in for a negative balance of the water and we are eating away our future resources. This exactly was the issue that dragged Eucalyptus into the controversy as a 'tree that depletes our water tables'. The sorry state is that we do not yet have an unanimous account of the water budgets for Eucalyptus; for that matter we do not have such accounts for almost all trees around us. And Eucalyptus was probably singularly pointed at.

To avoid these confusions we need to know how much water a tree transpires in a day, in a year and in its lifetime. As usual, simpler the question, the more difficult it is to answer. Anil Graves from Auroville and Pedro Berlinner and Israel Gev from Israel have attempted to analyse exactly this in their paper (**page 196**) in this issue. Following the observations that the water table in and around Auroville is falling down and that spuriously or otherwise this is coinciding with the planting of trees at the Ashram, the investigators were prompted to prepare a balance sheet of water use by the two most dominant trees planted here, viz. *Acacia auriculiformis* and *Peltophorum pterocarpum.*

The most significant contribution of their work, besides computing the water use by the trees, is the use of a non-destructive method of estimating the rate of sap flow through the plant. They did this by giving a heat pulse across the stem at a point and measuring the rate of diffusion of this heat through the sap as it moves through the stem. Since the heat is transported by convection slowly through the sap, the temperature sensing terminal, thermistor, kept at 15 mm above the source of the heat pulse starts registering a gradual rise in temperature with time and once the 'heat wave' passes the thermistor, it starts recording a fall in temperature. The time taken for maximum temperature to be recorded by the thermistor offers an indication of the velocity of sap flow. By suitable calibrations, Anil Grave's group measured the rate of water flow and from thence the total amount of water moved in a given time.

Accordingly they estimated that in a typical day during April, about 110 liters of water flows in *P. pterocarpum* and about 14 liters in *A. auriculiformis*. Extending the computations further and with certain appropriate assumptions, they estimate that the two species show a sap flux of 8150 and 2350 liters per tree respectively in an year. This accounts for about 13% of the rainfall received in the area occupied by the trees which might go up to about 30% if other losses are included. Thus the predominant trees of the Ashram do not appear detrimental for the water table of the area. Independent of the validity of these conclusions their study suggests a way of developing a balance sheet for the water use for trees, an issue that is bothering a lot many crop physiologists.

K. N. Ganeshaiah

Dental composite

The Council of Scientific and Industrial Research of the United Kingdom published in 1980 the results of an extensive survey conducted by it on the worldwide consumption of biomaterials and biomedical devices. Surprisingly, more than 37% of the total expenditure on medical materials and devices was on dental materials. The Sree Chitra Tirunal Institute for Medical Sciences and Technology, Thiruvananthapuram conducted a nation-wide survey of the consumption of biomaterials and devices in India in 1985. Interestingly it was found that 35% of the country's total outlay in the biomedical area went into dental materials and devices, very close to the global average.

The sad fact is that even now most of this demand is met by very expensive imports even for run-of-the-mill materials like stainless steel strips, and zinc phosphate cements.

There is a vague feeling that the Chitra Institute is interested in cardiac and neuro problems only. In fact the Institute has done considerable work in the area of dental care. Products such as dental bands, cements, and fillers have been developed by it over the years.

In this issue, V. Kalliyana Krishnan and V. Yamuna describe (**page 192**) the latest development on light cured radio-opaque composite fillers. UV cured fillers have been around for quite some time. But UV cured systems, especially with the mouth so close to the eyes, pose a potential hazard. Light cured composites are relatively new even abroad.

It is encouraging that this expensive and sophisticated material imported till now can be indigenously produced.

NATIONAL INSTITUTE OF IMMUNOLOGY
NEW DELHI 110 067

WANTED BIOMEDICAL SCIENTISTS

The National Institute of Immunology, New Delhi, would like to recruit **Biomedical Scientists** holding Indian citizenship as investigators leading their own groups responsible for research projects and teaching in the biomedical sciences. A demonstrated record of scientific productivity in the form of peer-reviewed publications in scientific journals of repute and/or internationally valid patents is essential, as is some indication of independence in scientific thinking. At least four years of post doctoral experience would be desirable.

Academic fields

The Institute's primary goal is to gain insights and understanding into the interplay of the immune system and diseases so as to facilitate the development of new approaches to their amelioration. Accordingly, interests and ideas in the study of mammalian systems at the level of transcriptional regulation, signal transduction, cell biology, cellular biochemistry, developmental biology, physiology and structural biology especially in the analysis of the immune system will be considered with much interest. Research areas involving host–pathogen interactions, covering the entire range of expertise and interest from the statistical and epidemiological to the cellular and molecular levels, will also be specially welcome. The Institute also invites scientists in the areas of bioinformatics and of primate biology to apply; scientists in these areas will be asked to function as central 'Service' facility resources in addition to their research as principal investigators.

Remuneration

Appointments offered will range from staff scientist III upwards (equivalent to university positions of lecturer or assistant professor upwards). Length of experience and the quality of the scientific productivity record will be major factors in deciding the level of appointment as well as the salary offered. Shared laboratory space and some initial intramural funding will be provided. Investigators are expected and will be encouraged to bring in extramural project-based funding for research expenses. Some housing is available on campus.

Application

Interested people are asked to send in a detailed biodata providing details of qualification, professional experience /achievements, positions held, with copies of notable papers where appropriate and the names, addresses, fax numbers, telephone numbers and the electronic mail addresses of three potential referees addressed to the Director, National Institute of Immunology, Aruna Asaf Ali Marg, New Delhi 110 067. People working in Govt/Autonomous/Public sector institutions within India are requested to have their applications forwarded through proper channels. The applications from candidates, residing in India, should accompany, except in case of Scheduled Castes/Tribes, a bank draft for Rs 15 in favour of the Director of the Institute. Out station candidates called for the interview shall be paid single second class rail fare to and fro by shortest route on production of the proof of the same. **Those who have already applied in response to the advertisement released in other issues, need not apply again.**

CURRENT SCIENCE

Volume 72 Number 3 10 February 1997

CORRESPONDENCE

Science education

I have read with interest Modak's article (*Curr. Sci.*, 1996, **71**, 960–967) on a subject which has been uppermost in the minds of many biologists. He should be congratulated on giving shape to the teaching of such an integrated course in life science in our universities. The suggestions made on the structure of the course, in his well thought out table on pp. 965–966, are very comprehensive, making room for choosing specialized streams and optional courses. Perhaps one can add that inclusion of field work in the 4th and 5th years would make the somewhat overweighted theoretical portions in each year a more holistic approach to a 5-year M Sc programme. Creativity can come, in a large measure, by exposing young minds to the marvels of Nature in addition to what they can get within the four walls of the laboratory.

The observations on managements and elected governments made by Modak are essentially what exist today. His remarks on teachers thriving on private coaching classes and tuitions while disregarding their professional obligations in the classroom and laboratory summarize the general apathy to the maintenance of high values in education by the teaching community. Many of us have been silent observers of this new and undesirable trend.

The nationwide debate on the pros and cons of the National Science University (NSU) has done us good in that it has raised hopes that, some day, in the not too distant future, a bold and imaginative government will muster the political will to overcome any obstacle in the establishment of the NSU. I, for one, live in the hope that Modak's proposals need not wait for the day NSU becomes a reality before this century is out. If the Vice-chancellors of all our universities press for implementation of the proposed NSU, it would be an achievement. I cannot understand why, if there can be exclusive universities for most of the Indian languages (and now the one contemplated for Urdu), and also for professional streams like Agriculture, Medicine, Veterinary sciences, what is the problem in an NSU exclusively for basic sciences and mathematics?

I would urge the Vice-chancellors of Indian universities to catalyse the UGC and the Inter-University Board to initiate a plan of action for this 5-year integrated course not only in the life sciences but also in other disciplines of the physical sciences. The unseen hand behind all the rush to seek admission to professional courses is really the parental anxiety to see their wards take to, willy-nilly, medical and engineering courses. If this psychology is to undergo a change, scholarships/fellowships have to be offered liberally to assist the discerning science students to opt for a career in science of a very provocative type (which the integrated Masters' course can offer) albeit parental pressures.

T. S. SADASIVAN

'Gokulam', 86/1, M. K. Amman Koil
Street, Mylapore,
Madras 600 004, India

I was delighted to read the article 'Science Education in Indian Universities: Proposal for a 5-year integrated M Sc course in life sciences', by Sohan P. Modak (*Curr. Sci.*, 1996, **71**, 960–967). His concern and caution coupled with a positive proposal for a potentially beneficial course could be welcome by all concerned but it is only implementation that has always been a 'bottleneck' in this country. I am surprised that the author is unaware of an ongoing near-identical programme in life sciences at Bharathidasan University, Tiruchirapalli existing for nearly a decade now. This 5-year integrated programme, which is the brain-child of its earlier Vice-Chancellor A. Gnanam, attracts over thousand plus 2 completed applicants each year for the entrance test in which only 24 get selected. As the programme is that of the University, funded by the State Government, nearly 70% of the seats are reserved for various communities, leaving only 30% for open competition. If some central agencies come forward to fund this programme, nearly the reverse could be the situation. Although the students out of this programme prove infinitely superior to regular postgraduate students from other colleges and universities and have been successfully placed in academic institutions and industries in India and abroad, the programme cannot be considered a total success because of the usual bottlenecks. Among the important ones are – the lack of proper funding for recurring and non-recurring expenses in running the course, lack of adequate faculty and infrastructure, etc. We often have to be content with excellent proposals and programmes which cannot be implemented in this country with its complexity of problems and highly varied priorities of the powers that be.

CORRESPONDENCE

And now about urban langurs

Correspondence from Jayashree Datta 'Observations on urban rhesus monkeys' (*Curr. Sci.*, 1996, **71**, 941) makes interesting reading and deserves further study. In the same tone here is an observation about urban langurs which probably draws our attention on another aspect of human activity, viz. cutting trees.

I observed a drastic change in the behaviour of langurs (black-faced monkeys) around my town in Dharwad district of Karnataka. They seemed to have become cleverer (?) and bolder in a short period of about 20 years. Earlier whenever a troop of langurs descended on our kitchen garden, they used to sit on the roof top and wait for an opportunity to safely enter the garden. As soon as someone came close by or climbed the terrace they would run away and find another roof top some 100 metres or more away. They were generally timid, but they might have attacked the same garden the next day.

To my surprise I found that now they are not afraid and even sit on a neighbour's tree only 10 metres away. They skillfully avoid stones thrown at them but sit on the tree very obstinately. This behaviour is seen with several troops and is quite common. How did their behaviour change in such a short period? When I was talking to others who also had observed this change, an explanation was given and appears plausible: The forests in the area have been converted to agricultural land. The cultivation depends on rain and hence the land is barren after harvesting. The irrigated land (mostly well irrigated) is very well protected and monkeys are driven out of such areas. The trees (usually tamarind and some neem) around the town which used to shelter these monkeys have gradually disappeared. Hence out of sheer helplessness, they have learned to sit even at a close distance and avoid stones or any other missiles thrown at them. The vacant area in town also has decreased and the monkeys have to live closer to the humans.

OPINION

Impact of the new economic policy on science and technology in India

P. N. Andhare

The implications of new economic policy and liberalization for Science and Technology in India are discussed. The result of two conditions imposed by Govt Agencies before sanctioning of financial support is highlighted and a strong plea is made for withdrawal of these two conditions. The perils of evaluating S&T based upon profit generation instead of quest of knowledge are emphasized.

A cornerstone of the Government economic philosophy in the wake of liberalization and new economic policy is its STRONG BELIEF that the 'market' can be allowed to be the master, monitor, judge and guide of all its economic decisions. Having watched the stagnation of the last fifty years, one cannot find fault with this philosophy. Nevertheless, it needs to be pointed out that however wholesome this belief may be in the area of production, services and utilities provided by the state, blind extension of this belief to all segments of society could lead to an unmitigated disaster. This realization finds an echo in the increased allocation for health, education, infrastructure, etc. in the last budget. A struggle is, therefore, on in the minds of policy makers of India to identify sectors, where the influence of the 'market' has to be curtailed, lest it should become detrimental to the national interest.

Resource crunch in S&T

It may sound as incredible if a scientist were to suggest that market forces should not be allowed to dictate the growth and development of science and technology in India. Very few realize that science has its own limitations and that it too needs careful nurturing, it needs inputs of an order that cannot be provided by 'markets'. It is precisely for this reason that all nations stand solidly behind their S&T organizations, protecting them against the vicissitudes of market vagaries. However, under the influence of liberalization and new economic policy, the Government of India has embarked upon a strange scheme – which is designed specifically to foster S&T in India, but which ends up scuttling the very ship of S&T in India.

Critics would hardly agree. DST and DOE will be cited as examples of Government's strong commitment to S&T in India. The public at large is also impressed by financial allocations for these departments – viz. around Rs 500 crores p.a. As often pointed out, the resource crunch in Indian S&T establishment is nothing but a 'wolf's cry', with both DST and DOE returning unused crores of rupees annually earmarked to support S&T activities in India.

Why should Indian scientists complain about a resource crunch, when DST and DOE's annual grant go abegging for want of worthy project proposals – is a legitimate question that needs to be answered. A similar cry was heard last year from private sector about lack of liquidity in markets – though both Government of India and Reserve Bank vociferously denied this. This happened due to Government's decision that banks must increase their CRR, i.e. cash reserve ratio resulting in the so-called liquidity crunch making it difficult for private industry to raise short term loans from the banks, though the banks had ample money to lend. This bears a striking resemblance to the resource crunch faced by S&T in India. In our land of paradoxes, our Government is quite capable of killing a fly sitting on one's nose with a hammer and then feigning innocence and surprise at the sight of a bleeding nose.

Flawed policy of DST and DOE

Precisely the same thing is happening in the decision-making chambers of DST and DOE. Both these departments have imposed two draconian conditions on any S&T project submitted to them for financial support. These two conditions are so heavily skewed against R&D that they nip in bud any S&T proposal even before its evaluation on scientific merit. These two conditions are:

(i) A project proposal will be considered for financial support only, if industry is willing to put its money in the project.

(ii) Industry must also give an advance undertaking that it will productionize the R&D resulting from the project proposal.

Both these are eminently desirable conditions. The only difficulty is that they cannot be met in practice. Why should industry put its money in any external R&D when it can as well use it internally for its own profit making? Why and how should an industry give an undertaking that it would productionize R&D results in advance well before the commencement of a project leave alone its completion? This belies all logic, is against the very spirit of R&D and betrays total ignorance of the dynamics of R&D. Industry can never give such an undertaking nor can a scientist ever demand such an undertaking knowing fully well that the success ratio of any R&D project is well below unity. Both these conditions are impossible to meet in India. DST and DOE, privately concede this and officially insist on its fulfillment. This has resulted in virtual strangulation of Indian S&T in the last few years. These two conditions are responsible for the tragicomic situation – resulting in unused grants with DST and DOE on one hand, and unused labs and unutilized scientists on the other hand, in a large number of CSIR and defence labs. As long as these two conditions remain in force, S&T in India will continue to suffer from the resource crunch, despite plenty of money in the coffers of DST and DOE, just as industry is suffering from a liquidity crunch.

Influence

The problem of S&T in India is, however, graver. Unlike industry, it has no lobby of its own to plead for its cause. Science as a body is much less organized. Industry can mount a campaign through CII, FICCI, CHOGAM, etc. – whether it is a question of a liquidity crunch in the market, high lending rates in banks or imposition of the new income tax, MAT. Science enjoys no such clout in India. Science is often an orphan in India. Consequently its simple plea that it is not desirable to judge a S&T project only on the basis of industrial relevance, evokes no response. Expecting industry to put its money in external R&D and giving an undertaking to productionize such R&D in advance is the surest recipe to abort S&T progress in India. It is, therefore, all the more necessary that planners and policy makers of India listen to the real difficulties of S&T in India. They must not delude themselves into thinking that space and atomic energy is all that Indian Science is about. Indian S&T is much wider and broader than ISRO and DAE.

As a short term measure, therefore, DST and DOE must not insist on these two conditions of support from industry. As a long term measure, S&T must be freed from the clutches of market and motive for profit. A hunger for profit is overtaking thirst for knowledge, corrupting young minds in S&T. Knowledge is to be venerated not because it generates wealth. This is only incidental. The magnetism of an unanswered question holds greater charm in the realm of scientists than all the treasure of the profit seekers. The grandeur of science cannot coexist comfortably with the mundane pursuit of profit. Let us not mix the unmixable. This distorted emphasis on profit and market sustainability are no yardsticks to monitor the growth of science. Science is too valuable an asset to be discarded and disparaged because it is not always profitable. Let the new economic policy and liberalization introduce profit motive where it is due, i.e. in production establishments. Let profit not encroach upon the sacrosanct areas of Science and Technology, where value is held in higher esteem than cost. In our zeal for the lure of the new economic policy and blind faith in the golden mantra of profit, let us not forget that tea is best served hot, sherbet is best served cold – and not vice versa.

Conclusion

While it is acknowledged that all sections of society cannot be developed by dependence on market forces, it is argued in this article that science is one such sector of society. Release of grants by Government agencies only after industry agrees to put its own money in any R&D project and gives an advance undertaking that it will productionize the R&D are two conditions which are throttling Indian R&D. The component of knowledge generation must not be allowed to be eclipsed by the capacity for profit generation. Science is sustained more by the quest for knowledge and less by pursuit of profit. Funding agencies should not overlook this fact.

Southern India develops a hunch back

A. V. Sankaran

According to plate tectonic concepts, Earth's landmasses form a mosaic of more than a dozen major and several smaller plates (e.g. Indo-Australian Plate, African Plate, Pacific Plate, etc.) all floating over the mantle on a plastic or semi-soft layer of rock. The margins or the boundaries along which two or three major plates meet are usually the sites of tectonic activity, i.e. they are the zones of deformation like faulting; or, regions where ocean floors spread and oceanic ridges rise; or, they may be zones of convergence where one plate subducts and another overrides. While the plate boundaries are thus active, the main oceanic or continental crust, away from the boundaries and capping the plates, are usually passive. However, observations over the last two decades arising out of oceanographic expeditions, appear to belie some of these ideas about plate boundaries being exclusive sites of tectonic activity. Studies[1-3] of the Indian Ocean floor, south of the Indian Peninsula have revealed deformation and faulting in a region far from plate boundary and well within the Indo-Australian Plate. A 900 km long split has been created in this once united plate with the resultant two halves now moving in different directions[4]. Similarly, the Tien-Shan region in central Asia, far away from the collision zone, between India and Eurasia is undergoing deformation, currently[5].

Yet another instance of tectonic activity in a region far from plate boundaries has now been reported by Subrahmanya[6,7]. The area described by him is well within the continental plate making up the crust of southern Indian peninsula close to 13°N. Stretching east–west from Mulki on the west coast to Pulicat Lake, a little to the north of Madras, on the east coast, this Mulki–Pulicat Lake Axis (MPA) (Figure 1), marks a region of uplift due to sea-floor spreading along the Indian Ocean Ridge system. He has cited a number of evidences pointing to this uplift.

Uplift of continental land segments produce many geomorphological changes. The most noticeable ones are their effects on the drainage pattern. Rivers in the area may gradually change their courses or even get dismembered. If turbulent enough, the rivers can cut through the strata keeping pace with the uplift of land and develop, as a result, deep valleys or gorges while retaining their original courses unchanged. Also, changes in sea level take place, leading to emergence of land and accretion to the coastline. Besides, the neighbourhood of uplifted regions may experience seismic shocks of varying intensity.

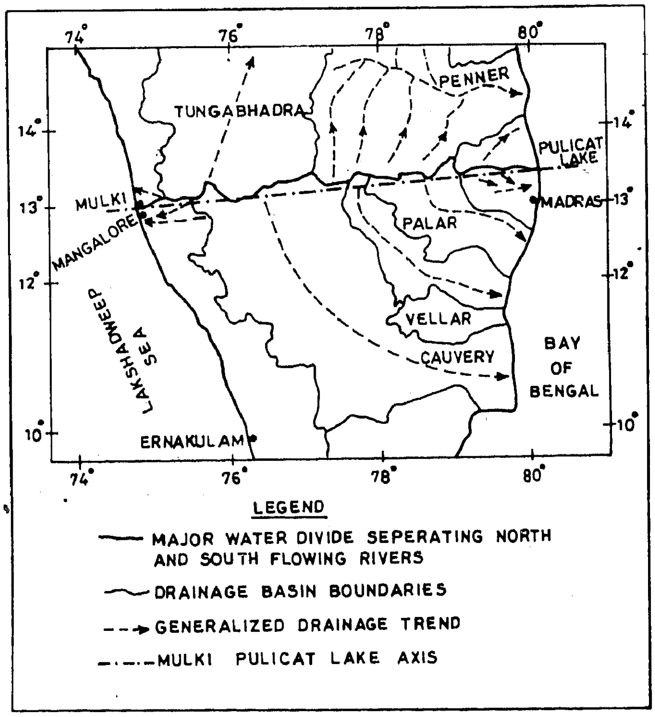

Figure 1. Generalized map of southern India, showing the Mulki–Pulicat Lake Axis (MPA), and the drainage pattern. The MPA is a zone of active uplift and marks a major water divide (after Subrahmanya[6]).

Subrahmanya has recognized all these changes along MPA, commencing from the west coast, passing through the Mysore Plateau to Pulicat Lake on the east. He has observed that the ridge making up the MPA is virtually the water divide and eastward flowing rivers on either side of this line have shifted in conformity with the new slope developed as a result of the uplift, leaving what are termed palaeochannels (ancient channels, now defunct), marking their trends during various stages of the uplift. Noteworthy examples are the easterly flowing Pennar and Palar (Figure 2), which according to palaeochannel evidences, have shifted northeast and southeast respectively as the land between these two rivers gradually lifted up to form the MPA ridge. The author has observed similar river shifts at the western end of the axis also, where the rivers drain into the Arabian Sea. Here, the westerly flowing Swarna, Netravathi and Gurupur, on either side of the MPA, have taken to northwesterly and southwesterly courses depending upon whether they are to the north or south of this axis.

There is also the view that this uplift was responsible for the dismemberment of South India's major river, Cauvery, which once was flowing closer to the MPA, but which subsequent to the uplift, split, leaving the dismembered segments – the Palar and Ponnaiyar rivers, and shifted to the present trend further south, before joining the Bay of Bengal[8,9]. Moreover, there is deepening of the river valleys, and development of river terraces at the western end of the MPA, along the Netravathi River drain-

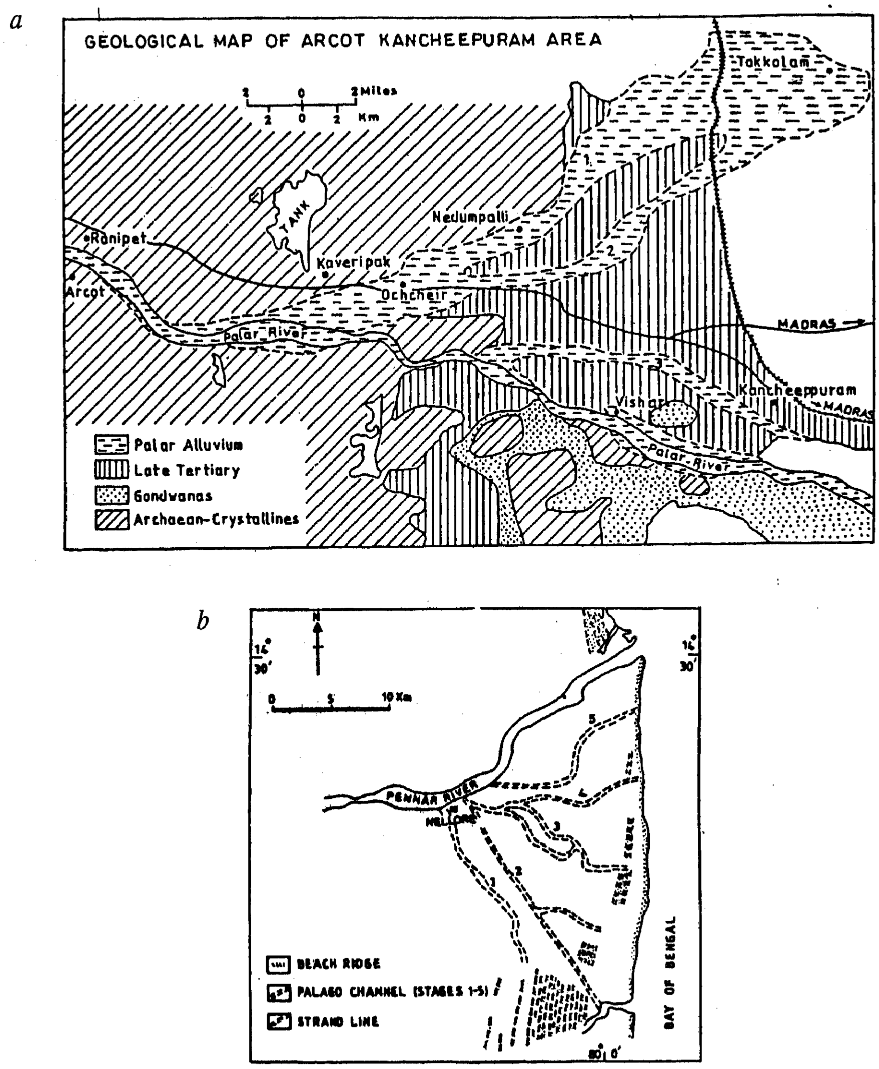

Figure 2. ***a***, Three palaeochannels (1,2, 3) showing the shifts of Palar flowing on the southern side of the MPA; ***b***, five palaeochannels 1–5 of Pennar flowing on the northern side of MPA (after Subrahmanya[6]).

ing into the Arabian sea. Marine shells and sands, pockets of saline waters[10] well inside both west and east coasts, apart from wave-cut platforms at different elevations (seen very well in St. Marys Islands off the west coast), have been noted. These are features arising out of falling sea level. The region close to 13°N has also recorded several seismic events[11] due to 'compression and uplift, related to the north–south oriented regional stress field'; and the Killari and Latur earthquake of 1993, in the adjoining State of Maharashtra, are believed by Subrahmanya to be related to this. Further, he feels that the 'region is likely to experience further upwarp and result in micro-seismicity to meso-seismicity to the south and mega-seismicity to the north of the MPA', thus dispelling the established notions that South India is seismically quiet and stable.

RESEARCH NEWS

New views on Andes mountains and South American plate movements

A. V. Sankaran

Mountain chains like the Himalayas, according to existing theories, are formed due to plate collisions, like the Indo-Australian continental plate pushing against Asian plate and folding up the intervening area as the lofty Himalayas. However, this theory fails to explain the rise of Andes along the west coast of South America or the Rocky mountains in North America as these continents had no opposing plate to collide against. Two geophysicists, R. M. Russo and P. G. Silver, have recently postulated[1,2] that the geologic forces in the mantle zone below South America is responsible for the rise of the Andes mountains. This view was a sequel to the unusual changes they noticed in the seismic wave propagation, while studying movement of mantle below the western edge of South America. Here the Pacific seafloor, the Nazca plate, subducts eastward (6 cm/year) into the Peru–Chile trench beneath the South American plate, while the latter glides westward (3 cm/ year) over the subducting plate. Contrary to the expected eastward movement of the mantle currents below the Nazca plate, the seismic data revealed movements of these currents, north and south, parallel to the western edge of the South American plate, i.e. at right angles to the expected orientation or flow direction (Figure 1).

The two geophysicists compared this anomalous movement of the mantle currents to that of water swept around a square-fronted boat pushing its way through the sea, implying thereby that the migration of the South American plate westward makes the mantle current flow north-south around the broad front edge of the plate. This motion, as if ploughing through the mantle, generates enormous pressures along the continent's western edge, enough to buckle the region up as Andes mountains. This upheaval is further facilitated by softening of the rocks present along this edge due to volcanic heat from the mantle escaping along the the Nazca plate's sinking edge.

These views received support when similar mantle current movements were observed in their computer experiments simulating a broad-edged continent coursing through mantle. They further found that in both simulated and real continents, the mantle forces exerted maximum impact at the junction where these currents split northward and southward (Figure 1), and as a conse-

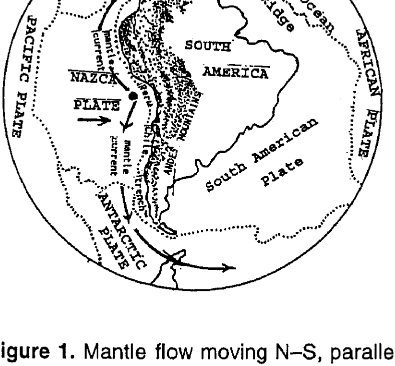

Figure 1. Mantle flow moving N–S, parallel to the edge of westward advancing South American plate. The Nazca plate is subducting into the Chile–Peru trench eastwards.

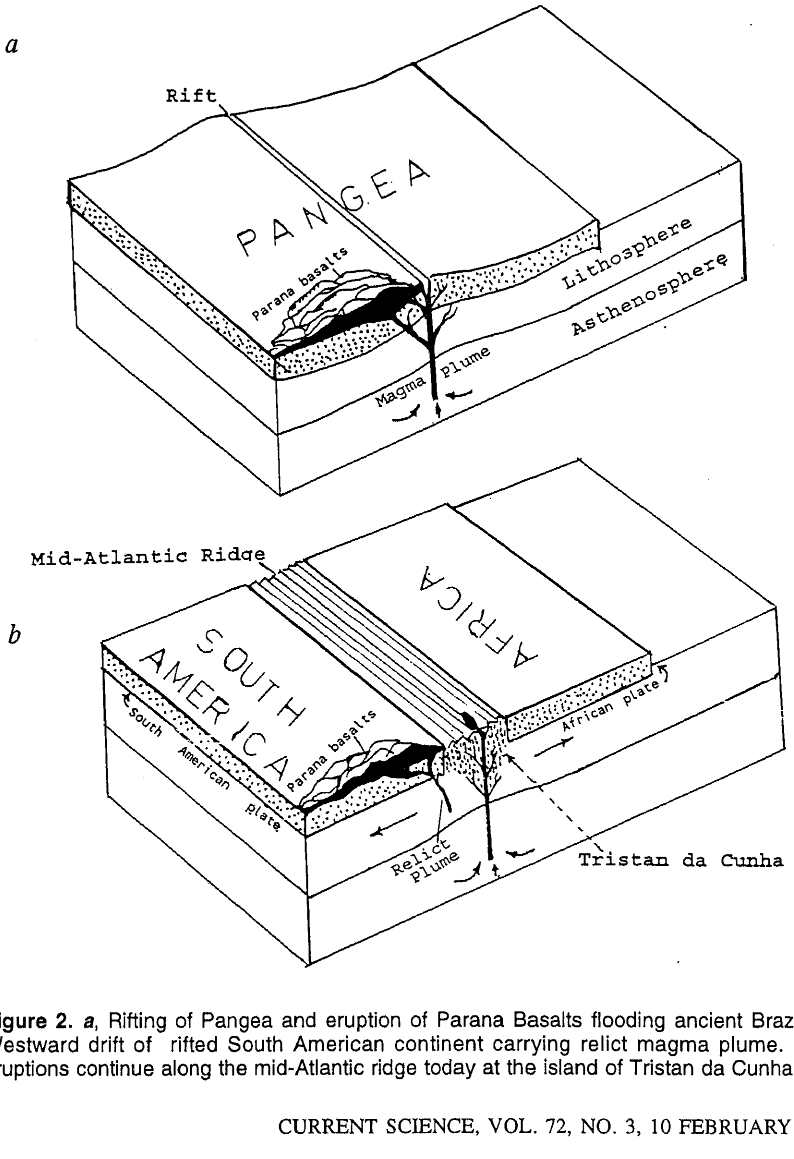

Figure 2. ***a***, Rifting of Pangea and eruption of Parana Basalts flooding ancient Brazil. ***b***, Westward drift of rifted South American continent carrying relict magma plume. Lava eruptions continue along the mid-Atlantic ridge today at the island of Tristan da Cunha.

quence, the Andes mountains are found to attain their widest extent at this mid-point, known as Altiplano. Further, these simulations indicated an eastward curving of the northern and southern tips of the continent, which indeed, they exhibit. The two found parallels in the rise of the North American Rocky mountains, as they too, 100 million years ago, had a similar subduction zone off their west coast, and likewise, exhibit the typical eastward bend, and a wide midsection.

As for the forces driving South American plate, both Russo and Silver are emphatic that this continent is swept westward by deep, wide, mantle currents from beneath the Atlantic Ocean. This view, no doubt, runs counter to the prevailing models of plate movements according to which the low viscosity layer, asthenosphere, separating crustal plates from the mantle, impedes mantle currents to carry the crustal plates along. While the Nazca plate is dragged eastwards by its sinking (subducting) edge, the South American plate is pushed from the rear, westwards, over the Nazca plate, by the emerging new crust – the mid-Atlantic ridge. This conventional 'ridge-push' view is very much doubted by both Russo and Silver who consider these forces alone are too inadequate for the build up of stresses and feel that these are augmented by the underlying mantle currents pulling to the west. But according to Richardson and Coblentz of University of Arizona, Tucson, the magnitude of drag forces from the mantle, invoked by Russo and Silver, are too small to carry the plate westwards[2]. According to their finite analysis calculations of stress measurements within the South American plate and also in the absence of any E–W stress-build expected if drag forces were significant, they feel that the movement of the South American plate should be essentially due to ridge-push force.

However, the theory, that mantle currents were the driving force received support from new data presented at last year's meeting of the American Geophysical Union, by geophysicists John Van Decar and David E. James of Carnegie Institution, Washington (DC). Using seismic tomography, a sort of CAT scan of the mantle below South America, they evaluated the seismometer recordings of earthquakes, worldwide, over a three year period. From these data on travel times of the waves which are influenced by the composition and temperature of the rock or zone through which they travel, the two were able to detect below Brazil presence of a relict or fossil structure of a magma plume which was once the conduit for the vast basalts (Parana basalts) that erupted in that country 130 million years ago (Figure 2 *a*). Obviously, this relict structure had moved 3000 kms westwards along with the South American plate from the original site (Figure 2 *b*). This is a strong indication that 'deep mantle currents carried both the mantle shaft and South American continent' together, though the eruptive source had still remained fixed as is evident from present day volcanic eruptions at Trista da Cunha in the middle of South Atlantic.

Split comets and crater chains (catenae)

A. V. Sankaran

There is hardly any planet in the Solar System which is not pock-marked by impact craters. Only about three years back, in July 1994, there was a live spectacle of the Shoemaker–Levy 9 comet (S–L9) crashing over Jupiter, an extremely rare celestial event that had mobilized scientists around the world to test some of their theoretical speculations about impacting bodies as well as impacted planets (or satellites). This comet had split into over twenty pieces during its close approach to Jupiter in 1992; these pieces, however, remained in the same orbit, though at some distance apart. Finally, one after another, two years later, they plunged on to this planet's thick gaseous surface, in a rare display of multiple impacts, generating huge plumes or clouds and leaving scars which gradually diffused into the planet's atmosphere.

While these were the outcome of the multiple crash over a gaseous planet like Jupiter, an event of similar nature by fragmented comets or rubble-asteroids over solid planets like Earth or Mars can result in carving of chain of craters (catenae). In fact, such crater chains produced by comets disrupted by tidal forces when they swept past Jupiter[1,2] have been spotted by the spacecraft *Voyager* on two of this planet's moons – Callisto and Ganymede. The craters on Callisto extend over a distance of 360 km with an average diameter of 24 km, while those on Ganymede are lesser in extent and sizes (Figure1). Now, after witnessing the crashes of S–L9 fragments, the origin of these crater chains, long considered enigmatic, no longer remain a mystery.

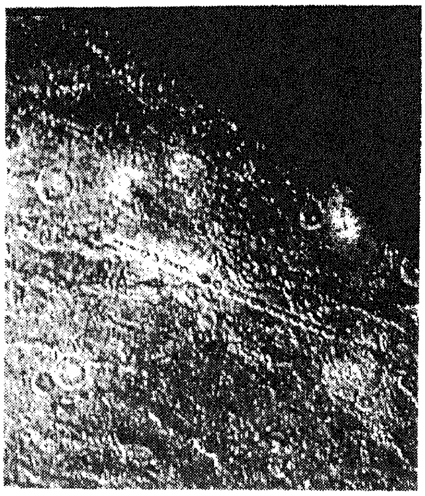

Figure 1. Crater chain on Callisto, the outermost moon of Jupiter, photographed by Voyager Spacecraft. This chain extends for 360 km and contains craters up to 24 km across. The origin of this chain was enigmatic until the impact of S–L9 fragments over Jupiter in 1994.

Recognition of crater chains on Callisto and Ganymede spurred searches for detecting similar ones on Earth and its moon also. Scientists consider their presence on Earth highly likely since our planet is known to have been severely

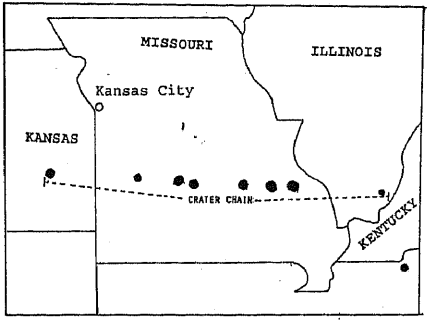

Figure 2. Crater chain extending for 700 km from Kansas to Illinois, USA.

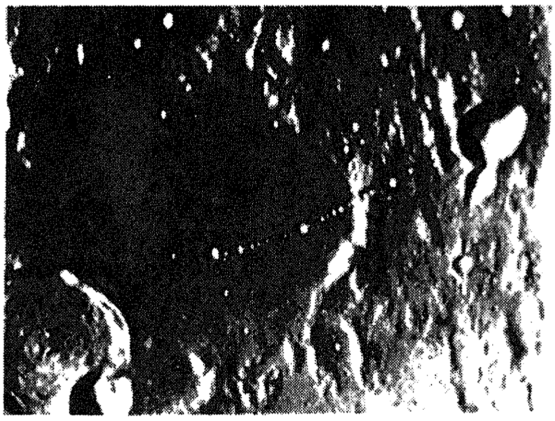

Figure 3. A string of craters in Moon, the Davy crater chain, 47 km long.

battered by meteorites and asteroids in its early past[3], though the likelihood of their unweathered preservation over the intervening millions of years is rather uncertain. In spite of this major constraint, recently it has been possible to decipher crater chains, one in Africa and another in North America through the data gathered by NASA's Imaging Radar Space Shuttle and, also over Earth's moon, from the Apollo Lunar Orbiter photographs[4,5]. The African Aorounga Crater (12.6 km diameter) in northern Chad[3] is now found to have two more craters to its NNE, and probably, a suspected third one also, all hidden below the sands of Sahara desert. They stretch for about 100 km, the largest among them measuring about 17 km across. These craters are believed to have been made by a comet or asteroid which split into fragments up to 1 km diameter, shortly before impacting , some 360 million years ago.

The second discovery[5] in North America is a string of eight craters ranging in size from 3 to 17 km and extending for 700 km from southern Illinois through Missouri to eastern Kansas (Figure 2). Hitherto, they were believed to be volcanic craters, but in the absence of any volcanism in the area and presence of shock produced minerals[6] at the site, they are now considered as coeval impact craters, about 330–310 million years old and created by a 'string of asteroids or cometary objects produced by breakup within the inner solar system[5]'. One more proven impact crater about 6 km in diameter (estimated age <300 million years) lying further east, some 420 km away, in eastern Kentuky[6], is also suspected to belong to the same Kansas–Illinois chain. Though the African craters too are dated around the same time, evaluation of various other data indicates that the craters in these continents were made by two different comets or asteroids. The crater chains found on our moon (Figure 3) range in length from 50 km (Davy chain) to 250 km (near Abulfeda crater) and are supposed to have been generated by comets disrupted tidally when they passed close to Earth or by rubble-pile asteroids[7].

Further comments on 'Fertile plants regenerated from mesophyll protoplasts of cold-tolerant rice' (J. N. Gupta, *Curr. Sci.*, 1995, 68, 755–758)

An unfortunate controversy has arisen regarding the above paper published in Current Science in September 1995. This was subsequently the subject of discussion in these columns in February 1996. The matter is closed with the publication of the following correspondence.

– Editors

This is a rebuttal of false allegations levelled by J. N. Gupta in his reply published in your esteemed journal (1996, **70**, 264–265). J. N. Gupta asserted in his reply that the work in question (published by J. N. Gupta and S. N. Gupta of Gorakhpur University in *Current Science*, 1995, **68**, 755–758) was done by him at ICAR Research Complex, Barapani (in my laboratory), it is a part of his Ph D thesis and that I misused my position to publish the same.

The allegations are false and without any element of truth. In fact, J. N. Gupta's claim is self-contradictory. On one hand, he says that his protocol published in *Current Science* in 1995 is entirely different from mine which was published in 1993 and on the other hand, he alleges that I misused my position and published his protocol. In order to resolve the controversy, I have now obtained a photocopy of his Ph D thesis and there is no mention of this work in his thesis. This shows that he had not done this work till the submission of his thesis and consequently; his claim to have done this work in my laboratory is wrong.

H. S. GUPTA

ICAR Research Complex
for NEH Region,
Barapani 793 103, India

I have the following comments regarding the paper in *Current Science.*

1. The published work in *Current Science* (1995, **68**, 755–758) is not a part of Mr J. N. Gupta's Ph D thesis.
2. I never consented to be a co-author in any of his research papers.

S. N. GUPTA

Department of Botany,
Gorakhpur University,
Gorakhpur 273 001, India

J. N. Gupta maintains:

1. The work reported in *Current Science* (1985, **68**, 755–758) on mesophyll protoplast to plant system in rice has been carried out by me. I never claimed that the reported genotype is a part of Ph D thesis.
2. I published this work from Gorakhpur University, Ludhiana and Gorakhpur; Punjab Agricultural University, Ludhiana and Directorate of Rice Research, Hyderabad respectively.

Comments on 'Interstratified low-Ti and high-Ti volcanics in arc-related Khairagarh Group of central India'

(Asthana *et al., Curr. Sci.,* 1996, **71**, 304–306)

1. In Figure 2, Asthana *et al.* have indicated CaO/$\mathrm{TiO_2}$ ratio for low-Ti basalt and high-Ti basalt, which is not consistent with the REE patterns for both the basalt. In low-Ti basalt CaO content is more than that of high-Ti basalt but the shown negative Eu anomaly for the low-Ti basalt is contradictory in respect to CaO content.

2. Derivation of arc-related magma is possible by thermal plumes mechanism involving a thin crust underplating and also by crust mantle recycling.

3. The authors have shown that two basalts have different REE patterns and have explained that which cannot be due to fractional crystallization/crustal contamination, however, the observed REE patterns can be derived from the crustal contamination and/or by combination of fractional crystallization and assimilation (FCA). From the given REE pattern it is hard to assess the heterogeneity of mantle source. Although the observed LREE patterns can be better explained by different degrees of partial melting of a rather homogeneous mantle source. The authors have put a question mark for LILE which is very important to decide low/high degree of partial melting as well as fractional crystallization. Hence, the degree of partial melting appears ambiguous. If the source is LILE enriched then mantle may reflect crustal recycling.

H. K. PANDEY

D. Asthana et al. reply:

1. CaO/$\mathrm{TiO_2}$ vs $\mathrm{TiO_2}$ and $\mathrm{Al_2O_3/TiO_2}$ vs $\mathrm{TiO_2}$ plots (Figure 2) clearly indicate a

fertile source for the high-Ti basalt (CaO/TiO_2 : 10–4; Al_2O_3/TiO_2 : 18–8)[1]. Assuming a similar source, our dataset[2] indicates that the low-Ti basalt (CaO/TiO_2 : 18–8; Al_2O_3/TiO_2 : 26–18) has formed by relatively higher degrees of partial melting than the high-Ti basalt. However, other datasets[3–5] clearly indicate that the source of the low-Ti basalt was relatively depleted (Cao/TiO_2 : 35–10; Al_2O_3/TiO_2 : 45–15). The low-Ti basalt was probably formed by remelting of a source which had undergone a previous episode of magma extraction[1]. Therefore, Figure 2 of our paper clearly indicates heterogeneity in the mantle source of the basalts which is also evident from their REE patterns (Figure 3). The two cross-cutting REE patterns cannot be obtained by different degrees of partial melting of a homogeneous source[6]. The HREE and Ti depletion in the low-Ti basalt can be due to the following reasons:

i) The low-Ti basalt was formed by relatively higher degrees of partial melting. ii) Mantle wedge of the low-Ti basalt has undergone previous episodes of magma extraction. iii) Mantle residue of the low-Ti basalt has higher proportions of garnet[7] and/or rutile[8].

The LREE enrichment in the low-Ti basalt clearly indicates higher subduction fluxes which is also evident from higher LILE contents in this basalt[9–11]. Pandey has stated that CaO content in the low-Ti basalt is more than high-Ti basalt, but from Table 1 it is evident that CaO content in the low-Ti basalt (7.08 wt%) is less than that in high-Ti basalt (8.50 wt%). Lower concentration of CaO in the low-Ti basalt probably indicates plagioclase fractionation which is also evident from negative Eu-anomaly shown by this basalt.

2. Derivation of arc-related magmas is not possible by thermal plumes or crustal underplating. Arc-related magmas are generated by decompression melting in the mantle wedge, augmented by aqueous fluids derived from the subducting oceanic crust[7,9,12–14].

3. Both the basaltic suites have high MgO-content (12–7 wt%) which rules out the possibility of their crustal contamination[15–17]. MgO > 6 wt% is generally considered as an adequate filter for AFC processes[15]. Therefore, we have not correlated the two suites by AFC. We have put a question mark for LILE because these are potentially mobile elements in altered volcanics such as Khairagarh basalts[18]. Therefore, LILE contents assume no importance in deciphering degrees of partial melting in these basalts. On the other hand, in altered and low grade volcanics, relatively immobile elements such as HFSE and REE assume vital importance in understanding degrees of partial melting and fractional crystallization[18]. LILE enrichment in the primitive arc-related magmas clearly indicates enrichment of the mantle wedge by subducting oceanic crust-derived fluids. Therefore, convergent margins are the zones of crust–mantle recycling.

Predicting monsoon rainfall and pressure indices from sea surface temperature

Several prediction techniques have been developed[1] to forecast the all India summer monsoon rainfall during the period, June–September. Among them, DWPJ-A, BMBPA-J and A-MR500 are found to be the most useful predictors. Nicholls[2] reported that the SST in the north Australia–Indonesian region (5–15°S, 120–160°E) is useful to predict monsoon rainfall.

Several studies[3–6] reported the relationship between SST in Indian ocean and monsoon rainfall over the Indian subcontinent. But, there is a divergent opinion on this aspect which is partly attributed to the poor quality of SST data in the Indian ocean[7]. Using the latest and high quality data set[8] on SST anomalies (MOHSST.6), an attempt is made here to re-examine the role of Indian Ocean SST in monsoon rainfall.

Data on SST anomalies (SSTA) in the grid, 0–5°N, 80–85°E, for the period, 1967–87 and three different rainfall series (R_1, All India monsoon rainfall (1847–1990) in mm based on arithmetic average of 16 representative stations[9]; R_2, arithmetic average of monsoon rainfall of 32 representative stations[10]; and R_3, rainfall anomalies[11] in cm) have been used in the computations. Correlation coefficients between SSTA and (i) DWPJ-A, (ii) BMBPA-J and (iii) A-MR500, are also computed. Data on DWPJ-A, BMBPA-J and A-MR500 are taken from the earlier studies[9,12,13].

Correlations have been computed with (– 1) year and (0) year lags following the method given by Nicholls[2] (correlations of 0.45 are significant at 95% level). The results are shown in Figure 1.

All India summer monsoon rainfall (R_1, R_2 and R_3) is strongly and positively correlated ($r = 0.75$) with the SSTA in the grid, 0–5°N; 80–85°E during October and November months of the previous year. SSTA in February (0 year) is also well correlated with R_1 (Figure 1 *a*). Negative and strong correlation is noticed between R_1, R_3 and SSTA in November, after the withdrawal of monsoon. This could be due to the advection of heat from west to east through equatorial jet which appears in October–November. The jet deepens the mixed layer depth towards east. This may distribute the heat to deeper depth and results in changes in SST anomalies[14].

SSTA in November (– 1 year) is strongly and negatively correlated (– 0.74) with DWPJ-A (Figure 1 *d*) while BMBPA-J is significantly and positively correlated (0.75) with the SSTA during November and December (Figure 1 *e*). A-MR500 is positively and significantly correlated (0.63) with the SSTA in October (– 1 year) (Figure 1 *f*).

To identify the changes in the correlations with time, sliding window correlations have been computed with a width of 26 years, from 1950 to 1991. Table 1 shows the sliding window correlations between SST and (a) monsoon rainfall (R_2), and (b) pressure indices (DWPJ-A, BMBPA-J). Correlations between April SST in the north Australia–Indonesian region (5–15°S; 120–160°E) and monsoon rainfall (R_2) are also shown in column (d) in Table 1. Correlation between October SST in the grid, 0–5°N; 80–85°E, and monsoon rainfall is significant from 1960 onwards. A similar feature is noticed between November SST (– 1 year) and DWPJ-A. But, BMBPA-J is significantly and positively correlated from 1953 onwards. All the correlations (columns a, b, c) show an increasing trend since 1950 onwards. A similar feature was also reported[1] earlier. The correlation between April SST in the north Australia–Indonesian region and monsoon rainfall (R_2) is significant and consistent throughout the study period and a decreasing trend is noticed in the recent period, 1966–91. It is interesting to see that the correlation during the above period is increased in the case of Indian ocean SST and R_2. This may be due to the warming of eastern equatorial Indian Ocean during the recent decades or due to the strong coupling between ocean–land–atmosphere system during the recent period compared with the earlier period as conjectured by Krishnakumar *et al.*[1]. The correlation between Indian monsoon rainfall and April SST in the north Australia–Indonesian region is found to be 0.55 (ref. 2) for the period, 1950–91. The correlation coefficient between October SST of the previous year in the grid, 0–5°N; 80–85°E and monsoon rainfall for the entire period is 0.40 which is statistically significant at 95% level.

From the overall results, it can be concluded that SSTA during October and November months in the EEIO is useful to predict monsoon rainfall and pressure indices. I am not aware of any earlier study which has shown the relationship between SSTA and pressure indices. It is inferred that the eastward propagating low frequency convective systems (LFCs) which originate in the warm pool region in the equatorial Indian ocean[15] could be the main mechanism behind the relationship of SSTA with different parameters discussed above. Secondly, the SST anomalies in this region can affect the 'walker circulation'[11], which is reflected in the strong correlations noticed between SST and (i) DWPJ-A, and (ii) BMBPA-J. Since the 500 mb ridge location along 75°E before monsoon is controlled by

Table 1. Sliding window correlation between SST and different parameters

Period	(a)	(b)	(c)	(d)
1950–75	0.11	– 0.20	0.26	0.51
1951–76	0.11	– 0.26	0.31	0.50
1952–77	0.09	– 0.26	0.35	0.46
1953–78	0.14	– 0.30	0.40	0.47
1954–79	0.15	– 0.31	0.41	0.45
1955–80	0.15	– 0.30	0.41	0.45
1956–81	0.15	– 0.37	0.43	0.55
1957–82	0.22	– 0.38	0.64	0.53
1958–83	0.35	– 0.51	0.58	0.55
1959–84	0.33	– 0.53	0.58	0.54
1960–85	0.35	– 0.59	0.64	0.51
1961–86	0.40	– 0.58	0.65	0.50
1962–87	0.57	– 0.66	0.66	0.50
1963–88	0.63	– 0.67	0.65	0.53
1964–89	0.65	– 0.67	0.65	0.53
1965–90	0.64	– 0.67	0.66	0.54
1966–91	0.67	– 0.65	–	0.47

(a) Correlation between October SST of the previous year in 0–5°N; 80–85°E and R_2.
(b) Correlation between November SST of the previous year in the same area and DWPJ-A.
(c) Correlation between November SST of the previous year in the above area and BMBPA-J.
(d) Correlation between April SST in the north Australia–Indonesia region (5–15°S; 120–160°E) and R_2.

the slowly varying planetary circulation and SST anomalies in the equatorial region[11] the observed relationship between October SSTA and A-MR500 is justified. More northward (southward) displacement of the 500 mb ridge position is a precursor for strong (weak) monsoon. In view of the above discussion, the observed strong correlation between October and November SSTA (– 1 year) and monsoon rainfall appears to be reasonable.

It is suggested that the SST in the EEIO may be included in the operational forecast model of India Meteorological Department.

On the age and fauna of beachrock of Kegaon Coast, Uran, Maharashtra

Outcrops of beachrock occur as isolated patches all along the coast of Maharashtra and comprise conglomerates, shell limestone bands and consolidated dune sand designated as 'karal'. The karal has been dated and found to range from Middle to Late Holocene in age[1–4]. The beachrock of Kegaon Coast of Uran forms the northernmost outcrop of the Raigad district. We aim to comment here on the age and paleoenvironment of the karal of Uran. It is well exposed in the intertidal and supratidal zone, stretching over 500 m and resting on highly fractured and well-jointed amygdular basalt. The karal has an uneven contact with basalt and exhibits varying thickness (Figure 1). The lithologic section studied shows development of approximately 3.5 m thick sediments with a basal conglomeritic zone followed by laminated shell limestone bands and dune sand (Figure 2).

Survey using theodolite was carried out at a location (18°52′58″N and 72°54′48″E) to determine the position of the beachrock with respect to the present MSL (Figure 3). The bases of conglomerate and dune sand lie at 1.5 m and 2.5 m above MSL respectively. However, the thickness of the beachrock varies from place to place. A section at Uran (18°50′25″N and 72°50′50″E) illustrated by Agarwal and Guzder[1] appears to be 4 m thick, while Kale *et al.*[5] gave a range of thickness from 1.5 m to 2 m for the beachrock and 0.9 m to 1.5 m for the dune sand exposed at a location having coordinates 18°52′30″N and 72°54′56″E.

The beachrock is compact, fairly well consolidated towards the bottom and fragile towards the top. The fauna recovered from the beachrock comprises mollusca, foraminifera, broken fragments of bryozoa, corals, etc. The shell limestone in particular, is rich in gastropods species,

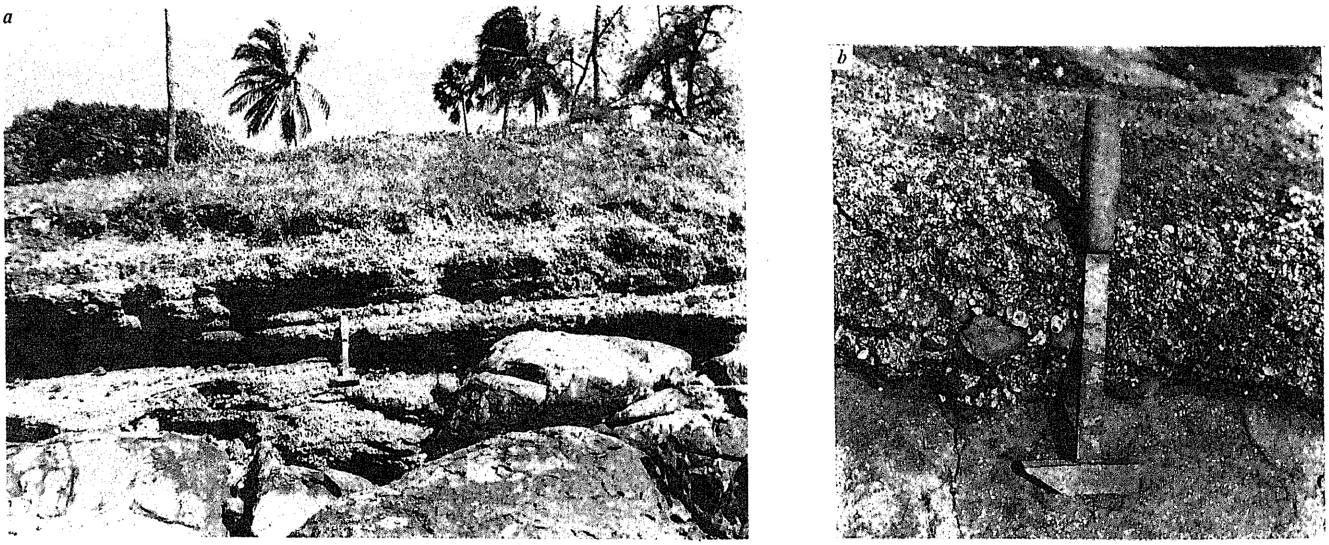

Figure 1. *a*, Outcrop of beachrock along Kegaon Coast, Uran. *b*, Contact between the basalt and beachrock.

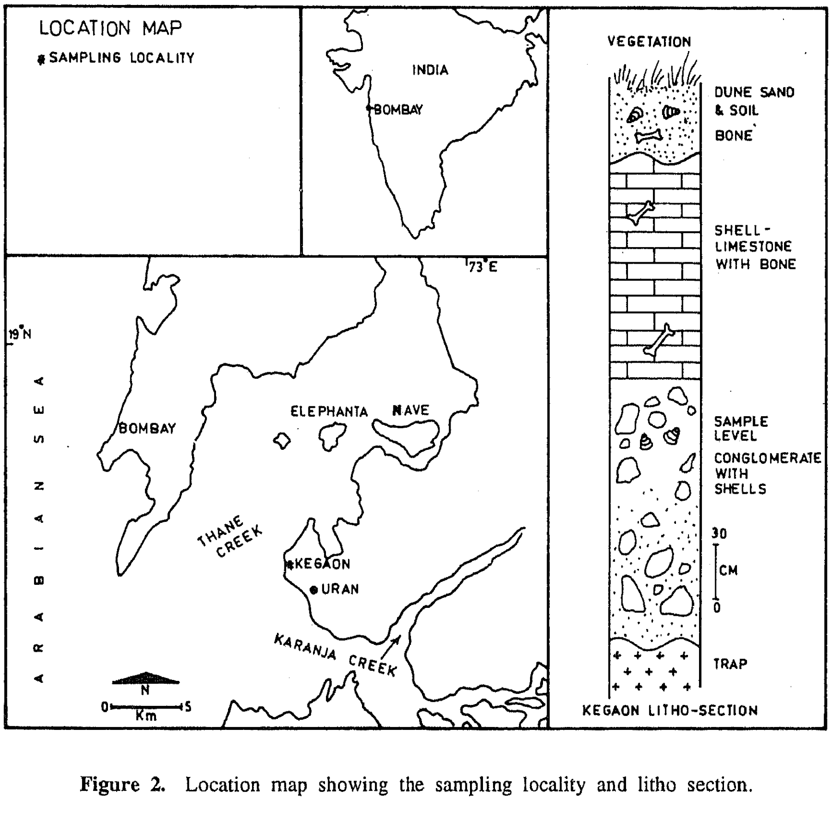

Figure 2. Location map showing the sampling locality and litho section.

viz. *Nerita (Theliostyla) oryzarum* (Recluse), *Trochus (Infunidibulum) radiatus* (Gmelin), *Clypeomorus moniliferous* (Kienar), *Cerithidea cingulata* (Gmelin), *Conus* sp., *Thias tissoti* (Petit), *Cantharus* sp., etc. The foraminifera belong to genera *Ammonia*, *Elphidium*, *Eponides*, *Bolivina*, *Brazalina*, *Siphogenerina*, etc. Fossils are rare in dune sand. Isolated mammalian bones and teeth occur at the contact of dune sand and shell limestone and in the upper part of the shell limestone band (Figure 2).

Being aragonitic, gastropod species *Nerita (Theliostyla) oryzarum* (Recluse) is used for carbon dating. The scanning electron microscope studies of the shell wall revealed undisturbed pattern of acicular aragonitic crystals (Figure 4 *a*), thereby ruling out any possibility of post-depositional leaching which otherwise would have affected the accuracy of the ^{14}C date. The measured radiocarbon age of the sample (BS 1204) is 1170 ± 90 years BP. This age when corrected using the radiocarbon age calibration programme for marine data base of Struiver and Braziunas[6] gives the calibrated age as 700 ± 70 years BP. A radiocarbon date BP 600 ± 80 for a fossil mangrove wood (BS 1051) from mud beach at Rewas, south of present locality across the Dharmtar Creek[7] revealed a relatively younger age for the sediments in the vicinity.

Formation of beachrock is a regional phenomenon and its distribution is related to time and altitude with respect to present day MSL. For Holocene, the global trends of elevation versus time plot indicate that older the strata, the higher or deeper is the position with respect to zero elevation[8]. Interestingly, Kale *et al.*[5] on the basis of fluorine/phosphate ratio of a mammalian bone assigned Late Pleistocene age and suggested that the beachrock of Uran is older than that occurring south of Thane Creek. Contrary to this, ^{14}C date obtained from *Nerita* sp. suggests that it is the youngest of beachrocks so

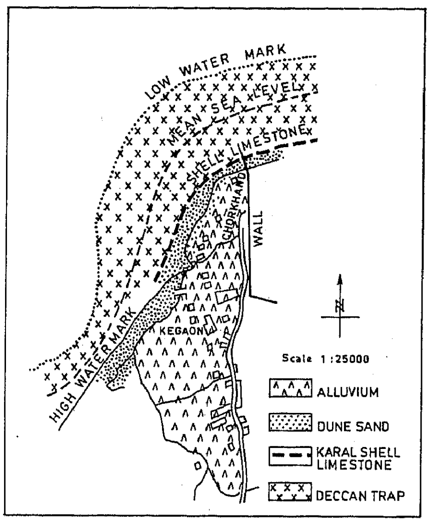

Figure 3. Position of beachrock with respect to main sea level.

far reported from west coast of Maharashtra. Hence, conclusions drawn by Kale *et al.*[5] regarding the Late Pleistocene age for the Uran rock are not tenable as during the Late Pleistocene, globally the sea level was much lower (120 ± 20 m). Therefore, only a localized single isolated patch cannot be older in age while all other available dates are in the range of Mid to Late Holocene.

Thus, the fragmentary mammalian bones seem to be of derived nature, further confirming that definite Late Pleistocene deposits along the west coast of Maharashtra are yet to be recorded[4].

From foregoing discussion it is evident that there existed a higher strand line along the coast of Uran at about 700 ± 70 years BP. Deposition of beachrock commenced with transgressive pulse, resulting into formation of conglomerate comprising angular to subrounded pebbles and cobbles of basalts, molluscan shell fragments and other bioclasts. These are further lithified by acicular aragonitic cement (Figure 4 *b*). Thin aragonitic coatings, observed around the sediment grains as revealed under SEM, indicate deposition in the lower intertidal zone[9]. Due to subsequent fall in sea-level, conglomerate and shell limestone were covered by dune sand. The upper portion of shell limestone and dune sand is highly fragile and yet to be lithified. However, a little amount of calcitic cement has developed due to influence of meteoric water (Figure 4 *c*).

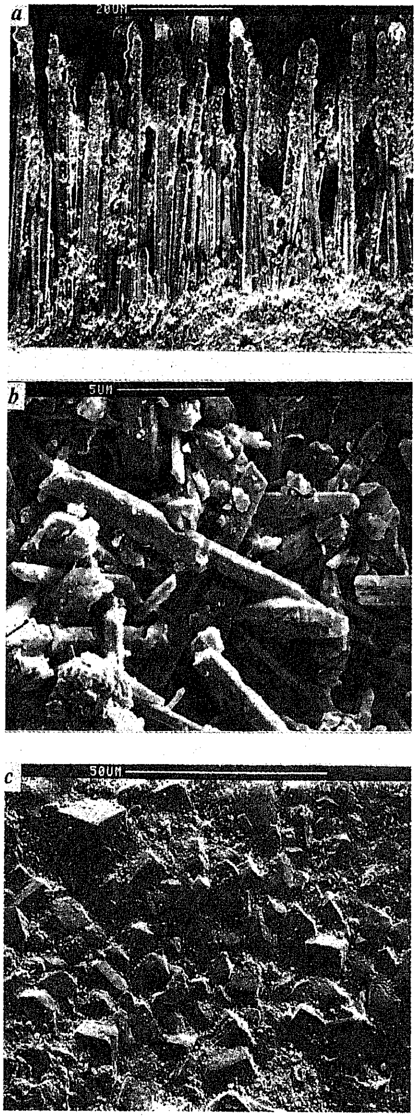

Figure 4. *a*, SEM photograph of the shell wall of *Nerita (Theliostyla) oryzarum* showing undisturbed acicular aragonitic crystals. *b*, SEM photograph showing acicular aragonitic cement as thin coating around sediment grains. *c*, Interstitial calcitic cement developed due to meteoric water.

Thus, the karal of Uran has been deposited under a Late Holocene transgressive pulse which lasted for a few hundred years only. Presently, the coast of Uran is under active erosion and the karal is subjected to a rapid destruction.

Parasitic infestation on commercially important sardines

In India, sardines (*Sardinella* spp) constitute the single genus with highest level of production[1]. Such important fishes are frequently encountered with parasitic infestation. But detailed knowledge on the different parasites of sardine is scanty[2–4]. Apart from the oldest records, nothing is known on the parasites that live at the expense of sardines.

During biological observations on the *Sardinella* spp of east coast of India, several sardines with external parasitic infestations were noticed. More than 25 isopod parasites belonging to the genus *Nerocila* were collected from the sardines *Sardinella gibbosa*, *S. albella* and *S. dayi*. Most of the parasites (83%) were attached on the opercular region. On the caudal region of the sardines the *Nerocila* sp. attachment was 17%. About 79% of the parasites attached on the anterior region was only on the left side of the host fish. The position of attachment was a little angular. The appendages in the anterior region of the parasite were curved and pointed to establish a firm grip of the host tissue. The infected area or area of the attachment of the parasite on sardine was devoid of scales and outer dermal layer. Skin lesion was also observed at the site of attachment. The *Nerocila* sp. was found to carry eggs and larvae in the egg pouch on the ventral side of the trunk. An instance of hyperparasitism (Figure 1) was also encountered. In a specimen of *Nerocila* collected from *S. gibbosa*, a copepode parasite belonging to Lernaeoceriformes *Lernaeconicus* sp. was noticed. The anterior part of *Lamaeonicus* sp. was buried inside tissues under the large egg mass on the ventral side of the host.

$$K = \frac{\text{Body weight} - \text{Gonad weight} (\times 100)}{\text{Length}^3}$$

The condition factor calculated for the parasitized sardines (0.38 ± 0.06) and non-parasitized sardines (0.9 ± 0.04) (collected in the same catch, same season and length range 12–14 cm TL) indicated that the parasitic infestation has affected the *K* value. The reduction in *K* value in the parasitized fishes has been ascribed because of the retardation of the gonadal development due to parasitic infection. This was further reinforced by the maturity studies carried out on the gonads of parasitized and non-parasitized sardines. In all the parasitized sardines the testis and ovary are in early stages of development and in some cases gonadal differentiation had not taken place. But in non-parasitized sardines the testis and ovary had attained maturing conditions just prior to spawning.

In addition to the isopod parasites, Lernaeoceriformes a copepod, parasite, *Peroderma sardinellae*[5] were also collected in large numbers from *S. albella*, and *S. sirm*. *P. sardinellae* was found to be a tissue borer making holes (2–4 mm diameter, depth up to inner organs) on the host body. The entire body of the parasite was buried (Figure 2) inside the bore except the egg sac. The bore was mostly (90%) in slanting position. There was no indication of scales on the bore and scales at the margin of the bore showed signs of drilling, with concave erroded margin. The parasite was covered by chitinous jacket and had anastomosing rhizoid structures on their antero-lateral side to absorb nourishment from the host. The condition factor calculated for *P. sardinellae*-infected fish was (0.3 ± 0.03) low when compared with non-parasitized fishes (0.9 ± 0.04). *P. sardinellae*-infected fishes had retarded maturity conditions when compared with non-parasitized fishes in similar lengths group. In the parasitized sardines the length range from 11 to 14 cm TL, the gonadal maturation has not taken place. The gonads remained as immature testis and ovary. But in the non-parasitized fishes the gonads developed prespawning conditions both in the males and females.

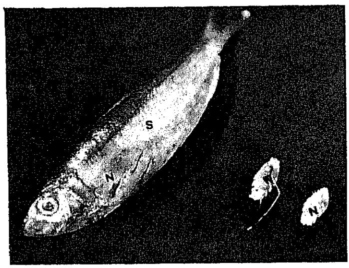

Figure 1. Sardines (S) parasitized by the isopod *Nerocila* sp. (N). An isolated *Nerocila* sp. infected by *Lernaeonicus* sp. showing hyperparasitism.

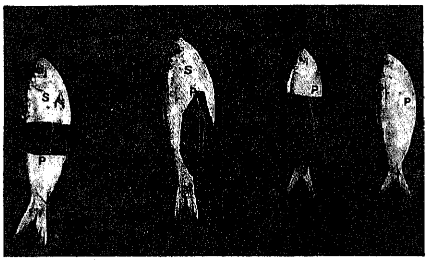

Figure 2. Sardines (S) parasitized by *Peroderma sardinellae*. The parasites are buried inside the host tissue, only the egg strings are seen outside.

GENERAL ARTICLE

Transgenic plants and biosafety concerns in India

P. K. Ghosh

The application of genetically modified plants in agriculture would be one of the many scientific inputs to accomplish increased agricultural production. The concerns are the risks and the magnitude of the consequences to the environment. Interestingly after scientifically generating data on safety, certain countries have approved the large-scale use of some transgenic crops. India started its field experiments in open environment using transgenics from 1995. The Government of India set out the rules and regulations for handling the genetically modified organisms (GMOs) which include transgenic plants, in 1989 through its Environment Protection Act, 1986 (EPA). The rules narrate procedures for conducting R&D experiments using GMOs as well as for large-scale applications, using them. Following the clearance under EPA, the transgenic plants are eligible for evaluation in the All India Coordinated Trial (AICT) procedures of the Ministry of Agriculture and Cooperation (MOA) for release by the latter for commercial applications in Indian agriculture.

THE protection and preservation of the environment in India is vested upon the government. The Central Government had enacted the environment protection laws from the Ministry of Environment and Forests (MOEF) from time to time to preserve the environment and to protect it from damage. Protection of environment includes assessment of the effects of substances or organisms to animal and plant health besides their effects both on the ecosystem and on the surroundings. In pursuance of the aims and objectives of preserving the environment, the Central Government from the MOEF had promulgated in December 1989 the rules and procedures for the manufacture, import, use, research and release of genetically modified organisms (GMOs) as well as products made by the use of such organisms. These orders were necessary, as the organisms and substances made by the use of genetic engineering hold potential risks to human and the environment. Therefore, without adequately assessing the environmental risks, their use or release into the open environment was considered unsafe and unwise. The intentions of such rules and regulations had never been to hinder or retard the progress of science and technology but to ensure adequately that the use of such products or life forms were safe to the environment, and beneficial to the human beings.

In this paper the biosafety concerns from the use of *transgenic plants* are discussed. Together with this, the existing rules and regulations for using such plants are also briefly enumerated.

Background information and historical highlights

India has realized that to sharply increase the food, feed and fibre production from the current level, there is no escape from use of modern biotechnology. Modern biotechnology includes isolation and purification of target DNA, RNA and protein (enzymes, hormones); cloning and amplification of genes; construction of vectors and hosts; standardization of cell or tissue culture techniques; optimization of downstream processing methods for the handling and stabilization of either the gene products or the GMOs. Genetically modified organisms are the organisms which have been modified through human intervention by recombinant DNA technology, and which are either self-replicating species or which replicate via a host organism, or which have reproductive capabilities. GMOs *exclude* organisms produced by breeding as well as organisms produced by the intraorganism rearrangement of genetic materials by physical methods or by chemical means.

India is spread over 3,287,263 sq km and is the 7th largest country in the world. Its population was 885 million in mid 1993 (16% of global population) which is expected to rise to 1015 million by 2000 AD, and 2530 million by 2050 AD. More agricultural yield is,

P. K. Ghosh is in the Department of Biotechnology, C.G.O. Complex, Lodi Road, New Delhi 110 003, India.

therefore, absolutely necessary for enabling to feed the growing population. The food grains production in India is on the rise; it increased from 176.4 million metric tonnes (mmt) in 1990–91 to 189.8 mmt during 1994–95 (ref. 1). However the increases are almost proportional to the rise in the population and therefore the per capita consumption has remained almost static during the last one decade. In order to maintain the current growth rate in agricultural crops as well as to improve upon the present yields further, various means are to be adopted. Use of modern biotechnology, involving the application of genetically modified plants, would be one of the many scientific inputs to agriculture to accomplish increased production. However, our unfamiliarity with these new inventions has made us more than concerned and alert to deal with them. This situation is true not only in India but also in all the developing countries as well as in the developed nations.

Current biosafety concerns

The main concerns are the right assessment of the magnitude of the consequences from the use of genetically modified plants to the habitat including human and animals, the flora and fauna, and the environment. Certain hereditary traits are targeted for transfer into the transgenic plants by using recombinant DNA technology as discussed subsequently in this text. The concerns[2] are that the chemical herbicide-resistant plants may confer new properties to the near-relative wild plants to make them also resistant to herbicides by transferring the resistant pollens to them and thus may transform them into plants, resistant to the currently used chemical herbicides. This situation would not be controllable by the known chemical herbicides and therefore agricultural production would become more expensive; viral disease-resistant plants may provide opportunities to evolve newer virulent strains of plant viruses by recombination between the viral genes contained in the modified transgenic plants and other infecting viruses against which the target plants are not protected; insect-resistant plants (for example, developed by incorporating specific *Bacillus thuringiensis* (*Bt*) genes, coding for proteins toxic to pests, into plants) may create situations of fast loosing the biopesticide value of the gene products (and therefore the genes),

Table 1. Transgenic crops approved in USA for commercial use

Product	Genetically altered traits	Company	Year of approval and product name, if any
Tomato	Delayed ripening	Calgene	1994, Flaver Savr™
	Delayed ripening	DNA Plant Tech.	1995, Endless Summer™
	Delayed ripening	Monsanto	1995
	Thicker skin and altered pectin content	Zeneca/Petaseed	1995
Cotton	*Bt* gene incorporated plants (ballworm and budworm resistant)	Monsanto	1995, Bollgard™
	Resistant to bromoxynil	Calgene	1995, BXN Cotton™
	Resistant to glyphosate	Monsanto	1996, Round up ready™
	Resistant to sulphomoyl urea	Dupont	1996
Soybean	Resistant to glyphosate	Monsanto	1995, Round up ready™
Potato	*Bt* gene incorporated (Colorado potato beetle resistant)	Monsanto	1995, New Leaf™
	Insect resistant (*Bt* gene incorporated)	Monsanto	1996
Maize	*Bt* gene incorporated (resistant to cornborer)	Ciba-Geigy	1995, Maximizer™
	Resistant glufosinate	Devalb	1996
	Resistant to glufosinate	Agro Evo	1996, Liberty Link™
	Male sterility	Plant Genetic Sys.	1996
	Bt gene incorporated (resistant to cornborer)	Monsanto	1996, Yeild Gard™
	Bt gene incorporated (resistant to cornborer)	Northrup King	1996
Rapeseed/ canola	Altered oil composition (high lauric acid)	Calgene	1995, Laurical™
Squash	Resistant to viruses	Asgrow	1995, Freedom II™

TM = Trademark.

as resistant insects are expected to be developed faster than is surmised, by excessively deploying such transgenic plants in the open environment. Besides, there are also concerns that the use of some of these plants and their products in the human food chain could prove allergic to some people[3].

Current global scenario

Interestingly, after conducting risk assessments and after the evaluation of their hazards by own methods, certain countries have already permitted the use of some transgenic plants in their commercial agriculture. China was the first country to introduce in the early 1990s the viral-resistant tobacco and later the viral-resistant tomato for commercial use[4]. Subsequently in May 1994, Calgene Inc., USA introduced its Flavr Savr^{TM} delayed ripening tomato[2,4] for commercial use. By the end of May 1996, seven transgenic crops involving 10 traits, using 19 processes were approved for commercial use[4] in USA (Table 1).

According to one estimate, up to the end of December 1995, nearly 3650 field trials had been conducted the world over[4], and as already indicated above, several plants have been authorized for commercial exploitation in USA. Information about approval from other countries was not available but it is expected that several approvals might have been accorded in Canada, China, Japan, Australia, Argentina, Mexico and certain European countries. It is estimated by the author that currently in 1996 the world over about 4 million acres of land are used for genetically engineered crops in commercial agriculture and over 75% of the land use for transgenes is in the USA alone followed by Canada (15%) and other countries (10%) (ref. 5).

Countries are permitting the commercial use of transgenic plants obviously because they are satisfied about the biosafety aspects from their use. The approved plants must have also provided additional economic advantage in experimental trials by manifesting the properties imparted upon them through recombinant DNA technology, e.g. herbicide tolerance, increased insect resistance, specific viral disease resistance, etc.; it is too early, however, to be assured with certainty that in every case of large-scale use, the economic advantages are real and sustainable, till the world community uses these plants extensively over long periods. Already concerns have been raised on the utility of *Bt* cotton in USA[6]. However, the current tempo is to maximize the use of transgenic plants at least in certain industrialized countries. The use of transgenic plants with these imparted agronomic traits is therefore anticipated to increase, and may contribute to the economy a global market of between US$ 2 and 3 billion in 2000 AD and $ 6 billion in 2005 AD (ref. 4).

Globally at least 64 different commercially important species of plants have been utilized for incorporating transgenic traits; important among these are maize, soybean, cotton, tomato, potato, alfalfa, petunia, rape/mustard, rice, wheat, beet, barley, Bengal gram, cabbage and tobacco. The traits that have been targeted for genetic acquisitions by the plants could be classified broadly as 6 only (Table 2), and that the tolerance to herbicides head the list[2,4].

Field experiments using transgenics in India

In India, field experiments using transgenic plants began in 1995 when the first permit was issued to M/s Pro Agro Ltd., New Delhi in September 1994, to conduct field trials (in contained and controlled environment) at Gurgaon (Haryana) using transgenic rape seeds (*Brassica juncea*) containing Barstar genes (producing male sterile seeds) and Barnase genes (sterility restorer). Subsequently up to August 1996, permits have been issued for limited field trials using *Bt* gene incorporated tomato and cotton[7]. In these experiments the commercial interests had been to develop improved local varieties from the transgenics (by back crossing etc.). The primary concerns from the regulatory authorities were, however, to find answers to the questions of risks and environmental safety.

Indian rules and regulations on GMOs including transgenic plant varieties

The rules and regulations for the manufacture, use, export, import and storage of genetically engineered organisms have been notified in the official Gazette of the Government of India by the MOEF through their Notification No. 621 dated the 5th December 1989. The notification was issued by the Government by virtue of powers conferred upon it through the EPA, 1986. Any violation and noncompliance including nonreporting of the activities in this area would attract the punitive actions provided under the EPA.

The Department of Biotechnology (DBT) of the Ministry of Science and Technology implements the R&D experiments utilizing GMOs and rDNA products, while the MOEF implements the large-scale commercial use and deployment of these.

Table 2. Genetic transfer of traits in transgenic plants by recombinant DNA technology

- Herbicide tolerance.
- Insect resistance
- Viral disease tolerance
- Fungal disease tolerance
- Product quality improvements
- Others (production of speciality metabolites/ chemicals, incorporation of marker genes, stress-resistance properties, etc.)

Indian structure for R&D experiments using GMOs

For R&D experiments, the structures enumerated in the above-mentioned notification are that it directs creation of various committees with set objectives for observing and implementing biosafety guidelines. The biosafety guidelines, available from DBT[8] were prepared by the DBT in 1990 and subsequently revised in 1994. Every organization involved in R&D using GMOs is required to setup its Institutional Biosafety Committee (IBSC), which has a DBT nominee and which is the nodal point for interaction with the Government within the institution/organization. The Review Committee for Genetic Manipulation (RCGM) is a national committee functioning under the DBT and has the functions of reviewing all the approval of ongoing R&D projects on GMOs, undertakes field visits of sites of experimental facilities and issues clearance for import/export of etiologic agents, vectors, germplasms, organelle, etc. needed for experimental working, training and research. Based on the recommendation of the RCGM, trial permits are issued by the DBT. Experiments are monitored by the RCGM besides the IBSC; in addition, the concerned State Biotechnology Co-ordination Committees (SBCC) of each State and the District Level Committees (DLC) of each district are also involved in the inspection and monitoring of the experiments at the field sites.

Indian structure for large-scale applications using GMOs

The Genetic Engineering Approval Committee (GEAC) of the MOEF is the interministerial committee with subject specialists as Members, and is the Competent Authority for any large-scale use of GMOs. The MOEF would issue the authorization to applicants on the basis of approvals accorded by the GEAC. As in the R&D trials, the large-scale use authorized by the GEAC also involves the watch on field applications of GMOs by the SBCCs and the DLCs. The GEAC would also involve the user Ministries as well as the other regulatory authorities (for example, for Drugs and Pharmaceuticals, the Directorate General of Health Services are consulted; for other items the concerned administrative agencies are consulted) before authorizing any commercial use of GMOs and rDNA products. Eventually, it is the concerned Administrative Ministries which take over after the clearance under EPA is accorded by the MOEF.

Field trial methods using transgenic plants

Planned field experiments using transgenic plants are permitted only after a stepwise evaluation of the developmental process from lab scale to the growth chambers and greenhouse conditions are thoroughly evaluated. The data for evaluation may be generated in India or elsewhere. The documentation requires full characterization and description including the sequence of the target gene and its promoter sequence as well as the regulatory mechanism utilized in the expression casette, diagram of the expression casette to describe fully the marker genes used, the description of the restriction sites related to specific endonuclease, the cell lines used for shuttling and amplification of the expression casette, the method of construction of the target gene along with all the sequences added or deleted, the extent of target gene amplification into the host genome and the description of the amino acids sequence being transcribed by the target gene as well as the marker genes. Lab data are insisted upon to prove beyond doubt that the translated gene products as well as the plants are safe to the environment and the human beings. If such data are not available, these are asked for to be generated.

Certain criteria are insisted upon which are to be followed while conducting field trials in small scale (R&D experiments) or in large-scale as indicated below.

1. To maintain at least the minimum isolation distance recommended for raising 'Foundation Seeds' all around the transgenic plants. Within the isolation distances noncompatible crops could be grown. For the details of the isolation distances for various crops, the publication of the Central Seed Certification Board of the Department of Agriculture and Cooperation, MOA for foundation seeds is to be followed[9].
2. Beyond the isolation distance, a few rows of the nontransgenic plants of the same crop to serve as a pollen trap may be grown.
3. In order to measure the distance of pollen escape from the target plants, within the isolation distance at intervals of 1 to 5 m nontransgenic plants can be grown; the seeds set at different isolation distances are then collected individually and separately aggregated, examined for the transgenic traits and the marker gene traits to work out and assess the extent and the distance of pollen transfer/flow from the target experimental sites.
4. Safety tests include the generation of data on the elucidation of genetic markers, host range requirements for vegetative growth, persistence and stability in small plots and experimental field trials for at least two years.
5. All the vegetative plants and left over seeds are to be destroyed by burning after the experiments.
6. The land may be left fallow next year after the experiments are over and the plants, if any, emerging in the soil from the seeds of last year may be destroyed.
7. The experimental field may be visited by the company authorized personnel only, and all records of visits are to be maintained.
8. Full account of transgenic seeds produced are to

be kept and no transgenic seeds be transacted or further propagated without authorization.

Discussion

The decisions for the application of transgenic plants in commercial agriculture are intimately connected with the concerns of safety among all cross sections of society. Decreased familiarity about the risks associated with their use aggravates the situation further. The concerns assume great significance particularly for applications in agriculture, as the products would be parts of human and animal food chain. It is for these primary reasons that the questions of safety from the application of transgenic plants are being passionately posed by different countries in different fora.

In order to be assured about all aspects of safety from the use of new technologies, it is surmised that certain steps taken sequentially, and answers found on sound step-by-step scientific assessment would resolve all the issues concerning safety[10]. It is mentioned in this connection that steps should be taken gradually and steadily without showing an iota of hurry and rush to reinstate the process of confidence building among all sectors of human community. In all initial assessments in the open environment, contained experiments must first be carried out. The purpose of containment is to ensure fool-proof methods of maintaining control over the spread of the GMOs in the open environment. Further, it is to reduce the exposure of GMOs to the personnel handling them, particularly in cases where the GMOs are associated with any human allergens. The following steps are logical, for which answers from different angles should be found in the registration document, based on which it would be possible to decide about safety and associated risks.

a) To systematically *identify the hazards* from the use of transgenic plants.
b) To *assess the risks* from each identified hazard by mounting convincing experiments and by collecting scientifically convincing data.
c) To *manage the risks* by applying logically valid strategies which would, inter-alia, include methods and procedures for minimizing risks.

In order to systematically identify the hazards and to assess the risks, information on the plants with transgenic traits should be generated on the following aspects.

1. Characteristics of the *donor organisms* providing the target nucleic acids. These may include the following:
a) Name of the donor organism with its identification characteristics with relevant reference to published information, if any.
b) Pathogenicity and toxicity characteristics to plants and animals.
c) Allergenicity characteristics to human along with identification of the allergenic substances, wherever possible.
d) The geographical origin of the organism, its distribution pattern and survival mechanism.
e) The method of transfer of its genetic materials to other organisms.
2. Characteristics of the *vectors* used: These may include the following:
a) The origin, identity and habitat of the vectors used.
b) The sequence, frequency of mobilization, specificity and marker genes if any, present in the vectors.
c) The abilities of the vectors to get established in other hosts; the hosts are also to be specified.
3. Characteristics of the *transgenic inserts*: These may include the following:
a) The specific functions coded by the inserted nucleic acid stretches including the marker gene inserts.
b) The expression of the nucleic acid products and their activities/properties.
c) The toxicity of the expression products on the host plant, if any.
d) The toxicity and allergenicity of the nucleic acid products to human and animals.
4. Characteristics of the *transgenic plants*: These may include the following:
a) Methods of detection of the transgenic plant in the environment.
b) Methods of detection and characterization of the escaped transgenic traits in the environment.
c) Toxicity and pathogenicity of the transgenic plants and their fruits to other plants in the ecosystem and the environment.
d) Possibility of and the extent of transgenic pollen escape and pollen transfer to wild near relatives, and the consequences to the environment.
e) Pathogenicity, toxicity and allergenicity of the transgenic plants and their fruits to human and animals.
f) Changes in the soil microflora due to cultivation of transgenic plants.

Information on many of the above questions may not yet be available. Therefore appropriate new experiments would have to be designed to gather data. Unfortunately, universal model experiments have not yet been designed for collecting data to reply to all the questions posed above. In seemingly controversial situations, the next best alternatives are to be found out after considerable scientific debate in the country. As regards generating information on toxicity and allergenicity, standard protocols are to be devised for collecting data utilizing small adult lab animals. The toxicity data should include acute as well as chronic toxicity studies; in doubtful situations genotoxicity, teratogenicity, neurotoxicity and immunotoxicity data should also be generated in small lab animals. Chronic toxicity data may also be generated using large locally available mammals like goats or sheeps or cows or dogs for about 8 to 12 months, but not less than 3 months. Utility of data from these animals may be debated for reasons of nonuniformity of genetic makeup of these animals as they are outbred, they are ruminants and are therefore more distantly related to human species than monkeys are. It is surmised, however, that the feeding data generated on these animals found in local environment would help in the resolution of local concerns about the risks from the long-term use of transgenic plants, entering directly or indirectly into the human food chain. Safety information generated on animals abundantly available in local environment and closely linked with human habitat is more ensuring to human than the extrapolated assurances drawn from data on distantly related varieties of small lab animals. Similarly, feeding data generated on some common avian species like sparrows, parrots or pigeons, which are found in the local ecosystem, is expected to put to rest the anticipated fear of creation of disturbances in the environment from the use of GMOs.

Once the questions regarding identifying the hazards and assessing the risks from various angles are resolved, it would be easier to *manage the risks* by applying logically valid strategies. The strategies are to be commensurate with the risks identified. The risk-management strategies for the release of transgenic plants may take into account the following:

a) Spacial separation for isolation, for preventing reproduction/fertilization and seed setting.
b) Biological prevention of flowering by making use of sterility properties, etc.
c) Human intervention for the removal of reproductive structures of flowers.
d) Controlling the reproductive structures of transgenic plants like the seeds and the plant propagules from unaccounted spread.
e) Controlling and destroying volunteer plants from the experimental field.
f) To take into account the proximity to human activity in case the transgenic plants have allergenic properties to human and animals.
g) Appropriate training of field personnel responsible for handling the transgenic plants.
h) Plans for handling unexpected events.
i) Documentation of previous published information, if any, including any documented evidence of effects of release to ecosystem.

For the assessment of hazards and risks, and for the management of risks the recombinant DNA safety guidelines of the DBT[8] should be strictly adhered to. In order to enable the GEAC of the Government of India in the MOEF about the proper assessment of risks and hazards from the use of transgenic plants before permitting their large-scale release, information on the lines discussed above is required to be submitted in a format which was devised for the purpose[11] by the government some years ago. The format needs to be updated.

Based on the assessment of the above information, prepared by the applicant in the form of a document which could be called the Registration Document, the GEAC would decide if clearance for commercial use would be permitted for specific transgenic plants. Up to the present time, however, no transgenic plant variety has yet been cleared by the Government of India for large-scale commercial use.

The GEAC clearance is only from the environmental angle under the EPA. Following the GEAC clearance, the applicants are to seek the clearance of the MOA, who in turn would then install the procedures of AICT through the system of Indian Council of Agricultural Research (ICAR), New Delhi. The final clearance of transgenic agricultural crops is accorded by the MOA through its well-established wing of assessment. Figure 1 shows schematically how a transgenic variety is to be eventually cleared by the Government for extensive field use, starting from research stage. It could be seen therefrom that the GEAC may, based on the information generated elsewhere by the applicant, or through the RCGM mechanism in India, accord approval to the applicant to proceed further for initiating the All India Coordinated Trial (AICT).

The experience gathered so far in India is indicative of a minimum time requirement of 3 years for generating information for submission to the GEAC for environmental clearances of GMOs, if proceeded through the IBSC and the RCGM mechanisms. Subsequently, the AICT would also take 1 to 3 years before enough data is generated for the MOA to enable the latter to decide on varietal clearance. In other words, a minimum of 4 to 6 years are required for transgenic plants to get entry into the Indian Commercial Agriculture.

Concluding remarks

The hazards and risks are to be assessed based on up-to-date current knowledge on the transgenic plants. The common elements and principles drawn from the experiences of other countries would go a long way in our understanding and in confidence building, although in certain situations experiments based on local conditions would have to be devised and local data generated. It has to be kept in mind that unfamiliarity with transgenics would not necessarily mean that they are *per se* unsafe. Our monitoring of the transgenics shall have to be intensified from simple visits and simple in-place observations of transgenic plants in fields by the expert team, to designing extensive research programmes to seek answers to specific safety questions. This would also need to broaden the knowledge base of the expert

breeders, the plant molecular biologists and above all the science managers and the authorities. The technological area being new, and the world knowledge being yet inadequate, several readjustments and redesigning of strategies to suit local conditions may be required. The future will tell how the countries would go about in this vital new technology area. In the meantime, keeping in view the global developments, specially in the developed world, it is being felt that precious time is running out fast from the hands of many developing countries including India. There has to be a greater sense of urgency in order to develop local capability to enable the generation of right information and to ensure the faster assessments of risks and hazards, and finally to decide on commercial applications quicker. In deciding commercial applications however, a cautious approach would be more desirable than is presently surmised globally in certain countries. A cautious approach is not to foster the creation of unscientific new barriers against the use of GMOs, but to bring in more transparency in their introduction in the open environment. From Indian experience, it appears that the first transgenic plant may get approved for use in commercial agriculture not before 1998.

REVIEW ARTICLE

How do proteins fold?

Utpal Nath and Jayant B. Udgaonkar

National Centre for Biological Sciences, TIFR Centre, P.O. Box 1234, Indian Institute of Science Campus, Bangalore 560 012, India

Understanding the mechanism by which an unfolded polypeptide chain folds to its unique, functional structure is a primary unsolved problem in biochemistry. Fundamental advances towards understanding how proteins fold have come from kinetic studies. Kinetic studies allow the dissection of the folding pathway of a protein into individual steps that are defined by partially-structured folding intermediates. Improvements in both the structural and temporal resolution of physical methods that are used to monitor the folding process, as well as the development of new methodologies, are now making it possible to obtain detailed structural information on protein folding pathways. The protein engineering methodology has been particularly useful in characterizing the structures of folding intermediates as well as the transition state of folding. Several characteristics of protein folding pathways have begun to emerge as general features for the folding of many different proteins. Progress in our understanding of how structure develops during folding is reviewed here.

PROTEINS fold to highly intricate and specific structures following their synthesis on ribosomes. The folding of nascent polypeptide chains to their native structures is an essential step in decoding genetic information to cellular activities, because only the folded conformation of a protein is functional. In contrast to our knowledge on transcription and translation as initial steps in information transfer in the cell, little is known about how proteins fold. Obtaining an understanding of the principles governing the formation of a fully-folded native protein from its unfolded state forms the basis of 'the protein folding problem'.

The earliest studies on protein folding date back to the 1920s, when Anson and Mirsky reported, for the first time, that the denaturation of many proteins is reversible[1,2]. This observation was extended by others[3,4], but it was not until 1961 that it was convincingly proven that the three-dimensional structure of a protein is dictated solely by its primary sequence[5,6]. In their classic work on bovine pancreatic ribonuclease A (RNase A), Anfinsen and his colleagues showed that reduced, denatured RNase A refolds spontaneously to its native conformation *in vitro* with the restoration of enzymatic activity as well as formation of its four native disulphide bridges, in the absence of any external assistance[7]. Since this landmark experiment of Anfinsen and his colleagues, research on protein folding has been proceeding at an explosive rate in many laboratories worldwide. Many excellent articles and books have reviewed different aspects of the protein folding problem[8–44]. This review will discuss the results of recent experimental studies that utilized kinetic methods, and will place special emphasis on how structure develops.

A review on protein folding remains incomplete without a discussion of the possible practical applications of protein folding studies[11,45]: (i) Virtually any foreign gene can be expressed in a host bacterium or a cell line using recombinant DNA technology. The expression of the recombinant gene often leads to the production of the protein in an inactive insoluble form, known as inclusion bodies[46]. Recovery of the active forms of these recombinant proteins from their inactive forms requires a good practical understanding of protein folding. (ii) Recombinant DNA techniques and modern peptide synthesis techniques permit the synthesis of large polypeptide chains of any desired sequence. Since the function of a protein is dictated by its three-dimensional structure, it is necessary to know, *a priori*, how a specific amino acid sequence will fold once synthesized. Though reports of designed amino acid sequences which adopt intended folds and possess physical properties similar to those of natural proteins are appearing with increasing frequency[40,47–50], designing proteins with novel biological functions still remains a major challenge. (iii) Although recombinant DNA techniques can be used to modify, at will, the amino acid sequence of an existing protein, the ability to do such protein-engineering in a rational manner depends on first gaining an understanding of how changing the sequence of a protein will alter its structure. (iv) Many diseases, including cystic fibrosis, scurvy, scrapie and Alzheimer's disease, are caused by mutations in essential cellular proteins leading to aggregation or misfolding of the proteins[51–53]. Understanding the mechanisms of these diseases and their subsequent treatment require an understanding of how the relevant proteins fold or misfold. (v) The progress of many genome projects has led to the availability of amino-acid sequences of thousands of proteins. To understand what the roles of many of these proteins in the cell are, it is important to obtain structural information on these proteins. Experimental methods of structure determination (X-ray crystallography and NMR) are slow, and are unable to keep up with the pace of discovery of new proteins. It has, therefore, become imperative to develop methods, far more reliable than those currently available, for the prediction of structure from amino-acid sequence. The reliability of the prediction methods will improve substantially only after an intimate understanding of the physico-chemical interactions that dictate protein folding is obtained. (vi) Ligand binding, protein–protein interactions and other aspects of protein structure–function relationships will be understood at the molecular level only after the principles governing protein folding are first elucidated.

Conceptual models

The necessity for folding pathways

The unfolded polypeptide chain of a protein can adopt very many possible conformations. A polypeptide chain with $n+1$ residues, each with an average m equally probable conformations, can have m^n possible conformations. Thermodynamic analysis of protein unfolding[54] suggests that $m \approx 8$ in a real, unfolded polypeptide chain. For a small protein of 100 amino acid residues, this suggests the occurrence of 8^{99} or 10^{89} conformations. Even if each conformation were sampled for only 10^{-13} seconds, which corresponds to the fastest rate of interconversion, it would require more than 10^{66} years for the polypeptide chain to sample 10^{89} conformations[55]. Real proteins fold, however, within seconds or minutes. This discrepancy between such a calculation and experimental results is known as the 'Levinthal Paradox', and led Levinthal to propose that there must be pathways for protein folding, which speed up the process markedly[56,57]. More recently, it has, however, been shown that if instead of a completely unbiased random search, a small and rational energy bias against locally unfavourable conformations is included in the calculation of the time taken to fold, Levinthal's time is reduced to a biologically meaningful time[55].

Framework model

According to the framework model[58], protein folding is hierarchical: during folding, secondary structural elements are formed initially, which then constitute the framework for subsequent formation of tertiary structure. A more extended interpretation of this model is that when folding commences, fluctuating segments of secondary structure first form and then coalesce so that the polypeptide

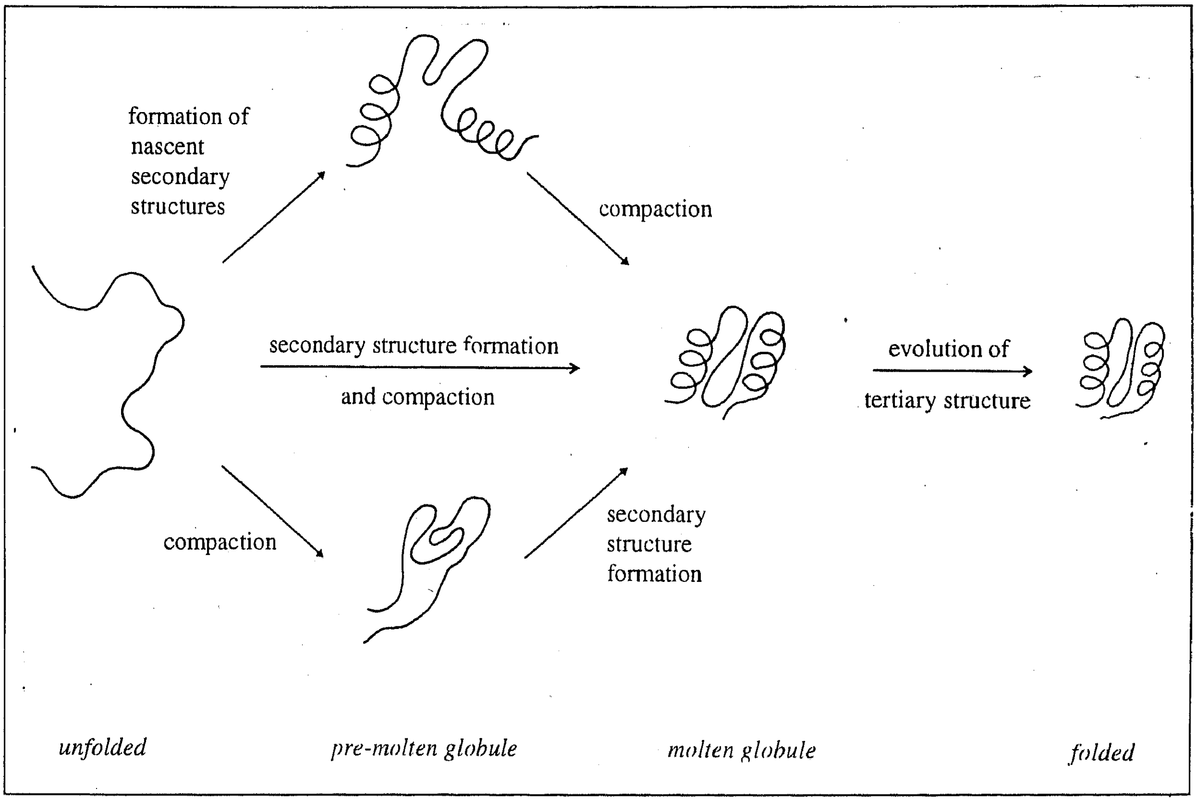

Figure 1. Models of protein folding. In the framework model (top pathway) nascent, fluctuating secondary structural elements form initially along the polypeptide chain. These coalesce to form a molten globule intermediate. In this model, the pre-molten globule is less compact, and any secondary structure present is very much more unstable than that in the molten globule. In the hydrophobic collapse model (bottom pathway), a non-specific collapse of the polypeptide chain occurs initially, and this facilitates subsequent formation of secondary structural elements, leading to the formation of the molten globule intermediate. In this model, the pre-molten globule is a disordered (structureless) form that is nearly as compact as the molten globule. The middle pathway depicts both collapse and secondary structure formation occurring simultaneously to yield the molten globule intermediate. In each case, the final tertiary structure evolves slowly from the molten globule intermediate.

chain becomes compact; the final tertiary structure forms subsequently. In part, this model reflects the realization that many proteins appear to have been assembled from segments of secondary structure[59,60]. It would appear that a consequence of the framework model would be that local conformation should depend on the local sequence. This appears, however, not to be true in native globular proteins: the same sequence can very often form different structures[61]. Nevertheless, experimental evidence for the framework model is strong[62–64]. It should be noted that elements of secondary structure (α helices and β-sheets) may not be stable sub-structures. This is, however, not an essential requirement for their assembly as long as once assembled, the complex of two or more secondary structural elements is more stable than the individual components. The diffusion–collision–adhesion model[65,66] proposed for the assembly of secondary structural units only demands that they be marginally stable and that the complex be more stable.

Hydrophobic collapse model

In the hydrophobic collapse model, the hydrophobic interaction, which can be described intuitively as water driving two non-polar molecules together, so that their contact with water is reduced, is thought to be the dominant interaction in determining the folding of a protein[67,68]. The idea is supported by the observation that the interiors of globular proteins comprise generally of hydrophobic amino acid residues. The non-specific nature of hydrophobic interactions suggested that they could form more quickly than other more specific interactions. This led to the idea of a hydrophobic collapse being the initial step in folding, in which non-polar side-chains are buried in a loose compact structure. Suggestive evidence for a rapid hydrophobic collapse has been found in staphylococcal nuclease, where C-terminal deletion mutant proteins are unfolded but compact and contain substantial secondary structure[69], and in kinetic folding experiments with dihydrofolate reductase (DHFR)[70]. The first direct evidence for the hydrophobic collapse model has been found in the case of barstar, where it has been shown that a non-specific hydrophobic collapse precedes the formation of any secondary structure or native tertiary interactions[71].

Nucleation–condensation–growth model

According to the nucleation–condensation–growth model[57,67,72–74], a region of the polypeptide chain serves as a nucleus for chain propagation to obtain the native state. The nucleus is expected to be unstable by itself, and is therefore present only fleetingly in the denatured state. Since the initial step is rate limiting, no intermediates beyond the nucleus are expected to accumulate in sufficiently detectable quantity, and the folding reaction is approximated by a two-state transition. The nucleation unit must be small enough for random search, and is expected to fully develop only in the transition state of folding. Direct evidence for the nucleation–condensation model is strongest for the folding of chymotrypsin inhibitor 2 (CI2) (ref. 74).

Jig-saw puzzle model

According to this model[75] of protein folding, the assembly of structural elements can occur in many different ways, analogous to the assembly of the pieces of a jig-saw puzzle which can be put together in various ways. There is no definite order to their assembly. In other words, there may not be any unique pathway for the folding of any protein. Recent studies suggest, however, that there are not a large number of equally accessible pathways by which a protein can fold; instead, folding occurs along one or a few well-defined sequential pathways with unique intermediates.

Development of structure during folding

The most useful way to analyse the pathway by which a protein folds is to characterize structurally and energetically all the intermediates that define the pathway[24]. Although new methodologies have been developed[62–64,76], partly folded intermediates that can be detected in kinetic studies are difficult to study because they have only a transient presence on the kinetic folding pathway. The cooperative nature of folding does not usually allow any intermediate to accumulate to any significant extent, and it is therefore difficult to characterize structurally a kinetic unfolding intermediate. Nevertheless, much information on how structure develops during folding has been obtained recently.

Early events in protein folding

The earliest steps in protein folding are usually studied using rapid kinetic measurements in the millisecond time domain. For many proteins, the earliest events of structure formation take place within the first 2–4 milliseconds, before they can be observed experimentally. The 'burst phase' change in the experimental observable used to monitor folding reports on the very early formation of structure. Information on what structure forms first can also be obtained by examining the structural features of the native protein which might fold faster than the global folding event. For example, a fragment of a protein which can assume native-like structure in isolation might form first during folding. Residual interactions and structures in the unfolded state may also play important roles in initial structure formation during folding[13,74,77–82]. Predictions have also been made on the early events in protein folding based on known native structures[83–86].

Formation of secondary structure. Two powerful probes used to study the formation of early secondary structure are far-UV circular dichroism (CD)-monitored stopped-flow kinetics[87,88] and pulsed hydrogen exchange in conjunction with NMR[19]. Folding of the peptide backbone can be monitored by measuring CD in the far-UV region; for example, formation of α-helices can be monitored at 222 nm. Initial formation of secondary structure has been observed for many proteins in far-UV CD-monitored kinetic experiments with millisecond time resolution[88–96]. In most of the stopped-flow CD studies reported so far, a significant amount of signal indicative of secondary structure was observed to have developed within the dead time of the measurement, much faster than the formation of the native structure[90–94]. In some cases, no further changes in ellipticity were found, suggesting that all the native secondary structure is formed in the earliest step[94,95]. In the case of tryptophan synthase, an overshoot of far-UV CD signal was, however, observed which was attributed to transient α-helical structures, which may not be native-like[94]. A similar overshoot was also observed in the case of hen lysozyme[90], which was attributed not to the formation of secondary structure, but to transient chain interactions, possibly associated with a disulphide bridge[91]. In some cases, several kinetic phases after the burst phase have been resolved[89,92], which are difficult to assign to the formation of specific structural features[89]. In the case of DHFR, several late phases have been resolved and assigned to the continued development of helices and rearrangement of the central β-sheet[92].

Whereas CD provides a useful index of secondary structure formation without defining the origin of specific features, pulsed hydrogen exchange labelling methods can detect the formation of specific secondary structure during folding[19,86]. The pulsed hydrogen exchange method, in which the ability of secondary structure to retard the exchange of peptide bond protons to exchange with solvent protons is measured, also allows the determination of the stabilities of the secondary structures formed at various times during the folding process. Early formation of native α-helix and β-sheet has been observed in cytochrome c (ref. 63), RNase A (ref. 62, 97), barnase[64], α-lactalbumin[98] and several other proteins[86]. A very early collapsed intermediate on the refolding pathway of the very fast folding form of unfolded RNase A has been shown to possess some marginally stable native-like secondary structural units[99].

Pulsed hydrogen exchange experiments may not, however, detect the initial formation of isolated elements of secondary structure. This has been shown by a comparison of hydrogen exchange data with that from far-UV CD in the cases of hen lysozyme[90] and cytochrome c (ref. 89). The structure formed in the initial stages of folding appeared to be too labile to afford significant protection from the relatively intense labelling pulse used in these experiments[31,99]. Formation of mutually stabilizing clusters of secondary structural elements is probably required to provide protection from exchange. This has been substantiated by studies of peptide fragments of regions of proteins which are protected from exchange initially in folding[100–102]. Thus, the combination of these techniques suggests the formation of abundant, but rapidly fluctuating, secondary structure in the earliest observable folding intermediates of hen lysozyme and cytochrome c.

Collapse and clustering of side chains. One of the major questions about very early events in protein folding is whether the initial formation of secondary structure precedes a global hydrophobic collapse of the polypeptide chain or whether the secondary structure is formed as a consequence of such a collapse[103]. This is a difficult question to answer because methods for the determination of a collapse of a polypeptide chain by direct measurements, for example, of the radius of gyration[104], are not readily coupled to rapid data acquisition systems.

Fluorescence is very useful in this context, because of its sensitivity to solvation, and both intrinsic and extrinsic probes have been used to investigate folding reactions. The fluorescence intensity of tryptophan residues is used typically to monitor folding in most kinetic studies because it is sensitive to environment, and its variation can be easily monitored[105,106]. In the case of a protein with a single tryptophan residue, the change in fluorescence can be interpreted in terms of the change in its particular environment[107,108]. Tryptophans have been engineered into various sites of lactate dehydrogenase to study the kinetics of folding of different parts of the structure[109]. A single tryptophan has been engineered into the interior of ubiquitin to monitor hydrophobic clustering[110,111]. In each of these cases, burst phase fluorescence changes within the dead time (5 milliseconds) of the measurement were observed, indicating that at least some side chain interactions involving the novel tryptophan residue had already formed on this time scale. The burst phase changes in intrinsic fluorescence intensity indicate that some degree of solvent exclusion, characteristic of the formation of at least a rudimentary hydrophobic core occurs within 5 milliseconds after commencement of folding.

In the folding pathway of DHFR, two tryptophan residues form rapidly a specific, native-like contact following an initial burst in secondary structure formation[92]. Fluorescence anisotropy decay measurements used to monitor the binding of a hydrophobic dye, 1-anilino 8-naphthalene sulphonic acid (ANS), during the folding of DHFR showed fluorescence anisotropy decay curves after 20 ms of refolding equivalent to those measured for the native protein[112], indicating that the molecule is similar in size to the native protein at this time point. In the case of hen lysozyme, which has six tryptophans, the fluorescence change within the first few milliseconds of refolding indicates the formation of hydrophobic clustering of at least a few tryptophan residues, although no significant hydrogen exchange protection is found within this time scale[113]. The earliest events in the refolding of lysozyme include both formation of substantial secondary structure, as detected by far-UV CD, and hydrophobic clustering, as indicated by change in fluorescence intensity[114].

Extrinsic probes, like ANS, serve as alternative probes to measure the hydrophobic collapse of a protein during folding[115]. The fluorescence of ANS is quenched in water and increases when it binds to clusters of hydrophobic residues in proteins. For many proteins, ANS fluorescence passes through a maximum during folding when partially folded intermediates accumulate transiently. For several proteins, including α-lactalbumin and β-lactamase, very little enhancement of ANS fluorescence during the first few milliseconds of folding was observed, suggesting that there was no extensive hydrophobic collapse in the initial intermediates[116]. In those experiments ANS was, however, present throughout the folding process, and it has been shown that the binding of ANS to intermediates affects the folding kinetics[117]. A new pulse labelling protocol, in which ANS was added after different times of refolding, has indeed shown that both α-lactalbumin and carbonic anhydrase undergo hydrophobic collapse very early during folding[117]. In the case of lysozyme, maximum ANS binding occurs in a burst phase within the dead time, when a substantial tryptophan intensity signal also develops. These data suggest that, in lysozyme, considerable hydrophobic collapse takes place during the initial step of folding, along with secondary structure formation[114]. Time-resolved fluorescence energy transfer measurements have been used to show that the initial folding intermediates of an immunoglobulin light chain[118], barstar[71] and apomyoglobin[119] are compact.

Direct measurements of protein compactness by small angle X-ray scattering have been performed recently both in equilibrium[120] and kinetic[121] experiments. By coupling this technique with rapid mixing, the compactness of an early intermediate in apomyoglobin could be determined in real time, within 100 milliseconds of commencement of folding[121]. Measurement of the scattering intensity spectrum indicates that the protein is indistinguishable in terms of its compactness from the native state much before folding is complete.

Side chain packing at the atomic level during folding has been studied recently by both one-dimensional[122,123] and two-dimensional[124] NMR in real time for systems that fold relatively slowly. Using this technique, the burst-phase intermediate of α-lactalbumin has been shown to resemble the acid-induced equilibrium intermediate of the same protein, which is a compact 'molten globule'[123].

The formation of molten globule intermediates is emerging as a common feature on the folding pathways of many proteins. Molten globules possess partial secondary structure stabilized by minimal native-like tertiary interactions, if any. The clustering of hydrophobic residues in these intermediates is monitored easily by their ability to bind hydrophobic dyes such as ANS[115,117,125]. Molten globules were first extensively characterized as equilibrium intermediates[38,116,126–128]. Recent studies have, however, shown that they do actually accumulate on the kinetic folding pathways, very often in a burst phase of a few milliseconds after commencement of folding[98,129]. While it is known that the equilibrium molten globules are compact, the degree of compactness in kinetic molten globules can only be inferred from their equilibrium counterparts.

Spectroscopic techniques that are available currently can measure the structural changes during folding only in the millisecond time scale, because the mixing deadtimes of the mechanical mixing devices are, with very few exceptions[130], typically 1–4 milliseconds. Thus, folding events occurring earlier than that are not observable. Methods are, however, being developed to probe structural events occurring on faster time scales by changing the physical[81,131–134] or chemical[135,136] conditions of the sample to initiate the folding reaction. Temperature jump experiments have been carried out in the case of cold-denatured barstar[81] and apomyoglobin[132] to study folding events in the microsecond timescale. Apomyoglobin forms a compact state within 20 microseconds, involving at least the A- and the H-helix backbones[132,133]. Submillisecond refolding events in the case of cytochrome c have been studied by initiating the refolding reaction either by laser-induced dissociation of a ligand[135] or by rapid photochemical electron transfer[136]. Analysis of the broadened NMR resonances, arising from the fast interconversion of folded and the unfolded species, has been applied to investigate submillisecond folding events in the case of monomeric repressor[137,138].

Kinetic barriers and fast folding reactions

The list of proteins that fold very rapidly (> 10 s^{-1} at the equilibrium unfolding transition midpoint at 25°C) is growing and includes cold shock protein B (CspB) (ref. 139), fragments of Streptococcal G protein[140,141] and cytochrome c (ref. 142). The rate of folding of a protein appears not to depend specifically on its size or structure, although in general, larger proteins fold more slowly. There also does not appear to be any correlation between stability and folding rate. Several marginally stable proteins, including CspB and a fragment of Streptococcal G protein[141], fold very rapidly. A mutation that decreases the stability of barstar also increases its rate of folding[143]. RNase A folds slower in conditions where it is more stable, and faster in conditions where it is less stable[144]. On the other hand, a relationship between the rate constant of folding and the stability of the native conformation has been demonstrated in the case of the Arc repressor[145] and ubiquitin[111].

The reasons why folding rates of proteins of similar size vary over a 100-fold range are not understood. Tertiary interactions of native[146] or non-native[142,147] origin sometimes act as kinetic barriers in folding. In the case of cytochrome c, a non-native interaction between the unfolded protein and the heme group is responsible for the slow folding of the protein; elimination of the interaction causes folding to occur 20-fold faster[142]. In the refolding of dimeric Arc repressor, formation of a set of native, partially buried, salt-bridge and hydrogen-bond interactions acts as a kinetic barrier. Replacement of these specific interactions with non-specific hydrophobic interactions accelerates the refolding rate of the protein by three orders of magnitude[146]. Equilibrium molten globules have a tendency to form soluble aggregates in solution, a property likely to be shared by kinetic molten globule intermediates. Disaggregation of a transiently formed kinetic molten globule aggregate on the folding pathway might also act as a rate limiting step during folding.

The transition state in protein folding

The transition state in a protein folding reaction is the structure that is at the highest energy level on the pathway of folding. The classical transition state theory of chemical reactions, proposed by Eyring[148], is applicable to chemical reactions involving the making or breaking of covalent bonds. In contrast, the protein folding reaction involves formation or destruction of mainly weak interactions. Nevertheless, transition state theory appears to be applicable to folding reactions as well. The results of kinetic studies for a few proteins have indicated that the transition state is compact[149] and more native-like than unfolded[150].

Structural information on the transition state of folding can also be extrapolated from characterization of the intermediates that precede the transition state on the folding or the unfolding pathway of a protein. Unfolding and refolding are linked by the principle of microscopic reversibility, requiring that under the same conditions, transition states and intermediates for unfolding and refolding should be identical[151]. In the case of the folding of RNase A in the absence of complications due to non-native interactions, it has, however, been proposed that the transition states on the folding and unfolding pathways are not identical[144].

The advantage of analysing the unfolding pathway is that it starts from the best defined structure on the folding pathway, that of the folded state. In addition, there are no complications arising from slow phases due to proline isomerization. The unfolding kinetics of most proteins have been described by simple two-state transitions, without the involvement of any unfolding intermediates. Recent studies on RNase A by NMR[152], and on barstar by optical probes[153] have, however, demonstrated the accumulation of kinetic intermediates on the unfolding pathway. The kinetic unfolding intermediate of barstar is compact with a dehydrated hydrophobic core and devoid of substantial secondary structure[153]. The unfolding of a low-pH equilibrium intermediate of a mutant form of apomyoglobin shows biphasic kinetics with a large burst phase change in fluorescence[154]. This has, however, been explained in terms of the intermediate being an ensemble of structurally related forms.

The transition state for the folding reaction, in which many hundreds of non-covalent interactions form, may not be unique, but may represent an ensemble of states with very similar energies, or one of several alternative states that are available. Theoretical studies suggest the latter possibility[155], but the demonstration that several proteins show apparent two-state folding/unfolding kinetics[139,156,157] suggests that if multiple transition states are present, they are equivalent in energy.

Late events in protein folding

The folding kinetics of most proteins, with few exceptions[139,157,158], show at least two distinct kinetic phases, usually a fast phase and at least one slow phase, with their time constants significantly different, even when equilibrium studies indicate a simple two-state unfolding transition. As discussed above, major structural changes towards the folded state like the hydrophobic collapse, H-bond formation, the packing of secondary structural elements, etc., appear to take place within the time scale of the fast phase. For many proteins, the reason for the slow processes is the isomerization about proline imide bonds[159–161]. It has been assumed generally that little structure formation accompanies this isomerization process, and for this reason, slow folding reactions have been used as model systems for the quantitative analysis of the coupling of intrinsically slower chemical processes (e.g. imide isomerization) to faster structure-forming folding reactions[162–164]. The extent of structure formation that occurs in a slow folding reaction has, however, not been well studied for any protein. In particular, the consolidation of tertiary interactions that must occur in this step is poorly understood.

The *X-Pro* imide bond, where *X* is any amino acid residue, is found to be in a *cis* conformation with reasonable frequency (approximately 7% of all prolyl peptide bonds) in many native proteins, whereas *cis* amide bonds have been observed only rarely[165]. In unfolded proteins and in peptides, the *trans* form of the *X-Pro* bond is favoured thermodynamically over its *cis* isomer, and the equilibrium distribution of the two forms are 70–90% and 10–30% for *trans* and *cis*, respectively[166,167]. The presence of these two forms in unfolded proteins gives rise to heterogeneity of the unfolded form[82]. The rates of *cis* ⇔ *trans* interconversions are slow and in the same time range as slow refolding reactions. This led Brandts and his colleagues[168] to propose that the slow phase of protein folding is because of the slow isomerization step from the non-native *trans* form of proline to its native *cis* form during folding. Many model proteins used for folding studies, such as RNase A, RNase T1, thioredoxin and barstar, have *cis* imide linkages, whereas others, such as hen lysozyme, T4 lysozyme, cytochrome c, etc., have only *trans* prolines. The refolding of proteins with one or more native *cis* prolyl imide bonds is usually dominated by slow kinetic phases, while the refolding of proteins containing all *trans* prolyl imide bonds is dominated by fast phases.

Proline isomerization has been implicated directly for being responsible for the slow refolding kinetics of RNase A (refs. 160,169,170), RNase T1 (ref. 159), staphylococcus nuclease[161] and thioredoxin[171]; replacement of *cis* prolines leads to the elimination of the slow-refolding reactions in these proteins. This effect is, however, not seen in the case of human lysozyme[172], indicating that factors other than *cis-trans* isomerization of *X-Pro* bond could also be responsible for slow-folding reactions in some proteins. A cystine knot loop threading mechanism has been suggested to be responsible for the slow phase in the unfolding of human beta-NGF[173].

Two slow phases are found in the refolding of two-disulphide derivatives of bovine pancreatic trypsin inhibitor (BPTI). Using energy calculations, Levitt[174] predicted that the native state was destabilized most strongly in molecules with *Pro8* in the non-native *cis* conformation (all prolyl peptidyl bonds are *trans* in native BPTI). This prediction was later confirmed experimentally[175]; replacing *Pro8* by glutamine in a two-disulphide variant of BPTI abolished the slowest phase of folding. This result implies that the incorrect conformation of a proline residue that destabilizes the native conformation the most, also leads to the strongest deceleration of folding.

Structural characterization of folding pathways by protein engineering methods

The advent of recombinant DNA techniques, which led to the birth of protein engineering, provided a powerful tool to study the contributions of individual amino acid residues to the conformation and folding of a protein. One of the principal goals of protein engineering methods has been to estimate the informational content of individual amino acid residue positions. The challenge is to determine the contributions of individual residues to the stability and folding of a specific protein. By careful equilibrium and kinetic analysis of mutant proteins, invaluable information can be obtained on the folding pathway of a protein, which is otherwise not available from the studies on the wild type protein.

Protein engineering and equilibrium intermediates

Folding intermediates are populated usually to a negligible extent at equilibrium because they are less stable than the fully folded protein. Thus, many of the small monomeric, single-domain proteins unfold through a highly cooperative process with no detectable accumulation of equilibrium intermediates between the fully folded and the unfolded forms[32]. Site-directed mutagenesis is a potential method for breaking down the cooperativity of the folding process so that folding intermediates accumulate at equilibrium and are more amenable to study[176]. Equilibrium folding intermediates have been populated to a significant extent by perturbing hydrophobic interactions in barnase[177] and by perturbing a buried hydrogen bond in barstar[178] and their structures have been studied spectroscopically.

Double mutant cycles

The extent of interaction between two residues in a folded protein can be estimated by using double mutant cycles[179,180]. The method consists of identifying two interacting residues in the folded protein and mutating them both independently and simultaneously. Then the differences in free energy of unfolding ($\Delta\Delta$Gs) of the three mutant proteins are measured with respect to the wild type protein. The comparison of the difference of the $\Delta\Delta$Gs of the two single mutant proteins with that of the $\Delta\Delta G$ of the double mutant protein indicates the extent of interaction between the two residues under study. The double mutant cycle allows the measurement of the changes in cooperativity along the folding pathway. This approach has been applied to barnase and the results indicated that during the refolding process cooperativity is still present in some regions of the folding intermediate[181].

Characterizing the transition state by protein engineering methods

Protein engineering methods offer a glimpse of the structure of the transition state of folding. Structural characterization of the transition state is achieved from the inferences of kinetic measurements on mutant proteins[24,64,151,182–184]. Sufficient experimental progress has now been made to validate this method and the theoretical basis is reasonably well established[185].

The method comprises of: (i) establishing and measuring the interactions that stabilize different parts of the molecule from experiments on the equilibrium stability of mutant proteins and (ii) using kinetic measurements of protein folding and unfolding to determine what fraction of the stabilization energy measured in (i) is used to stabilize the transition state for folding[182]. Each mutation engineered into the protein acts as a reporter group for the progress of folding at the appropriate position. The procedure gives a quantitative parameter, Φ, for the localized comparison of the transition state with the native state[182]. Φ is calculated as the change in the free energy difference between the transition state and the unfolded state relative to the change in the overall protein stability as a result of the mutation. In situations where a mutation has an identical energetic effect on the folded and transition states, $\Phi = 1$ and the interaction is assumed to be present in the transition state. In cases where $\Phi = 0$, the structure of the transition state in the region is assumed to be identical to that of the unfolded state. Fractional values of Φ, found frequently in the analysis of measurements of the CI2 folding, signify that the structure is weakened or that a dynamic equilibrium exists between folded and unfolded conformations. These fractional values of Φ are particularly difficult to interpret in structural terms[73,186].

Using the above method, the structures of transition states of several proteins have been characterized. The transition state of CI2 appears to be a globally collapsed state strongly resembling the folded protein but expanded by 30%, and lacking the specific hydrophobic packing characteristic of the native state[186–188]. Structural characterization of the transition state of barnase by protein engineering reveals that it is very similar to the folded state[23,182,184]. The major differences are a weakened main hydrophobic core, the disruption of a small subdomain and of some loops, and the unwinding of the amino termini of the two helices, and less secondary structure. As in the case of CI2 and barnase, considerable secondary structure is formed only after the transition state in folding of Arc repressor[189], CheY (ref. 190) and a fragment from GCN4 (ref. 191). Molecular dynamics simulation studies have also been used to study the structures of the transition states of CI2 (refs 192,193) and barnase[194]. A good correlation between the experimental and the theoretical results[195] corroborates the validity of the procedure of studying transition states by protein engineering.

Characterizing kinetic folding intermediates by protein engineering

Although spectroscopic probes such as fluorescence and circular dichroism provide useful information about structure, both at equilibrium and in kinetic studies, they monitor the structure at a macroscopic level. The structural information at the level of individual residues and atoms at equilibrium can be obtained only by NMR. The study of kinetics of structural changes at the atomic level during folding by stopped-flow NMR spectroscopy, which could be the best method to monitor protein folding, is, however, still at an early stage[123–124,152,196].

There are two existing procedures for analysing the structure of the transient intermediates with high structural resolution: pulsed hydrogen exchange[19,86,197] and protein engineering[198]. Although the protein engineering method reports only indirectly on structure, it is more powerful in being applicable to many more regions of the protein, including all the side chains and the hydrophobic core, and it is not just restricted to those NH groups that are protected sufficiently well to be resistant to exchange. Further, the protein engineering method gives information on energetics, and may also be extended to events that occur on shorter time scales than pulsed hydrogen exchange methods[73,81].

Protein engineering methods have been used to characterize transient intermediates on the folding pathways of barnase[198,199] and phosphoglycerate kinase[200]. The transient folding intermediate of barnase is characterized by relative positions of α-helices and β-sheet being native like, as well as the relative positions of β-strands within the sheet being native-like. The structure looks very much like the transition state, except that the intermediate has a weaker hydrophobic core[198,199]. The structure of the transient intermediate determined from protein engineering studies agrees well with that obtained from hydrogen exchange studies.

Engineering disulphide bonds to study protein folding

Protein folding has been studied by kinetic analysis of disulphide bond formation in proteins like BPTI, which requires formation of specific disulphide bonds for its folding[201]. Folding pathways of such proteins have been studied and trapped intermediates have been characterized by selectively mutating cysteine residues and measuring the rate of disulphide bond formation[202]. Engineered disulphide bonds have been used to report on the folding of specific regions of a protein[203], where formation of a disulphide bond is not required for folding. The engineered disulphide bond is expected to stabilize an early kinetic intermediate if the bond is located in the region which folds early in the pathway.

The introduction of free cysteine residues in phosphoglycerate kinase and the analysis of their reactivities during the folding reaction has also provided useful structural information about kinetic intermediates[204]. These studies suggest that the kinetic folding intermediates contain an ordered native-like secondary structure, especially near the centre of the protein, that is weakened at the periphery.

Concluding remarks

Experimental studies of protein folding are being provided with valuable insight from simplified statistical models[36,37,42]. Theoretical studies have now become sufficiently sophisticated to be able to describe many of the basic features of folding that are evident from experimental studies[155,192–195,205–208]. Clearly, the study of protein folding will benefit tremendously from the marriage of theoretical and experimental studies.

The results of experimental studies with millisecond time resolution on the folding pathways of many proteins, including RNase A (ref. 62,99), α-lactalbumin[98], lysozyme[30], apomyoglobin[129], cytochrome c (refs 89,135) and DHFR[95,112] suggest that compaction of the polypeptide chain and secondary structure formation occur simultaneously, because these two processes cannot be resolved temporally. It remains to be seen, whether the two processes indeed occur simultaneously in a faster time domain. Folding experiments have only recently entered the microsecond and nanosecond time domain, and the possibility of nanosecond circular dichroism measurements[209] holds great promise. Future studies will provide crucial information on how folding commences. In the case of barstar, it has been shown that a hydrophobic collapse precedes secondary structure formation[71], leading to the formation of a disordered (structure less) globule, and recent temperature jump experiments in the microsecond time scale[81] appear to support this result.

Partially folded forms of a protein can often be detected in equilibrium with the fully folded form, and much recent effort has gone into obtaining structural information on these forms[39], and relating them to structural intermediates that accumulate transiently on the direct folding pathway. In particular, hydrogen exchange measurements of proteins in the presence of mildly destabilizing concentrations of denaturants[210–214] yield structural information on partly unfolded forms of the protein in rapid equilibrium with the fully folded protein. These partly folded forms may or may not, however, represent structural intermediates on the direct folding pathway[213]. While in the case of cytochrome c, the partly unfolded forms do resemble structural intermediates that have been identified on the kinetic folding pathway[211], in the case of barnase, the partly unfolded form does not resemble the kinetic intermediate that has been structurally characterized[213]. It is essential to determine if partly folded forms of a protein, in equilibrium with either the unfolded state (in kinetic experiments) or with the folded state (in hydrogen exchange experiments), are tangibly present on the direct folding pathway. It has been shown recently that a non-native intermediate accumulates during the folding of β-lactoglobulin[215]. This has again highlighted the importance of demonstrating whether partly folded intermediates, which are observed in kinetic experiments, accumulate on the direct folding pathway or whether they are off-pathway dead-end intermediates[20].

Although it has now been clearly established that many proteins fold along one or more well-defined pathways, which involve intermediate structures that are only partly folded[16,27], recent studies have shown that the folding/unfolding of small proteins, such as CspB (ref. 139), CI2 (ref. 156), the IgG binding domain of streptococcal protein G (ref. 141), acyl-coenzyme binding protein[156], the SH3 domain of spectrin[217] and cytochrome c (refs. 142, 216) follow two-state kinetics: no intermediates are detectable between the unfolded and the folded state[218]. These observations have raised the question whether intermediates are essential because they guide the folding process along a pathway and thereby speed up the folding process, or whether they are only incidental to the folding process and accumulate simply because of the presence of kinetic barriers. Do intermediates that are too unstable to be optically detectable exist on the folding pathways of proteins that fold by apparent two-state behavior, where they function in a spectroscopically silent manner? Does the accumulation of a stable intermediate on a folding pathway actually cause folding to proceed slower than it would in its absence[64,111,120,144,219]? Identification of the natures of kinetic barriers that retard folding, and their structural description are major goals in the study of protein folding.

Received 16 December 1996; revised accepted 24 January 1997

Evaluation of a light cured dental composite containing a radiopaque glass filler

V. Kalliyana Krishnan and V. Yamuna

Biomedical Technology Wing, Sree Chitra Tirunal Institute for Medical Sciences & Technology, Poojappura, Thiruvananthapuram 695 012, India

Light curing dental composite pastes were prepared using an indigenously developed Bisphenol A-glycidyl methacrylate (BIS-GMA) resin and a commercially available radiopaque glass filler of different particle sizes. SEM examination of the virgin filler and composite surface revealed agglomeration of particles in virgin state and fine encapsulation of the filler particles in resin matrix of composite. Variation of the filler content shows that an amount of 220 phr (parts per hundred of resin mixture) of the radiopaque glass filler of larger grain size or 250 phr of the smaller grain size incorporated into the paste tends to improve the compressive strength and diametral tensile strength considerably compared to composite containing conventional quartz fillers.

DENTAL composites generally consist of a dimethacrylate organic binder resin such as bisphenol A-glycidyl methacrylate (BIS-GMA) and an inorganic resin filler such as quartz or glass modified with a silane to effect a strong bonding between the resin and the filler incorporated into the resin matrix. The nature and size of the filler play a dominant role in determining the final properties of the composite and its performance in the oral cavity[1]. Filler particles are found to have a particle size < 50 μm in conventional composites whereas microfilled composites contain fillers around 400 nm. Glass fillers with barium or strontium incorporated into it to induce radiopacity is widely used in many composites[2]. These radiopaque composites are widely used in posterior applications where stress-bearing materials are required and easy access to the clinician for examination is denied.

The development of the BIS-GMA resin monomer indigenously has been reported earlier[3]. Both chemical curing and light curing dental composites using this monomer resin and quartz as the filler were developed subsequently and subjected to exhaustive studies[4–7]. However, the need for radiopacity for monitoring the restored teeth prompted us to use a new radiopaque glass as filler material and the effect of the amount and particle size of this filler upon the properties of the light curing composites developed is reported here.

BIS-GMA resin synthesized in the laboratory and a radiopaque glass filler (GM 27884, M/s. Schott Glasswerke, Landshut, Germany) was used for the study. Three different grain sizes of the same glass were used [IDENT-NR-642907304 (0.7 μm), IDENT-NR-642907604 (1 μm), IDENT-NR-642907407 (1.5 μm)]. The composition of the glass is reported as SiO_2 55, BaO 25, B_2O_3 10 and Al_2O_3 10. The particle size distribution of the glass powder was determined using a particle size analyser (Galai Cis, Israel). A crosslinker triethyleneglycol dimethacrylate was used to thin down the viscous BIS-GMA to form the resin mixture and a photoinitiator (–) camphorquinone (both from Aldrich Chemical Co., USA) and other stabilizers were incorporated during paste preparation.

The glass filler particle was silanated using a 1% 3-(trimethoxysilyl) propyl methacrylate (97% Aldrich Chemical Co., USA) solution in acetone to ensure strong adhesion between the filler and the BIS-GMA resin. The solvent was allowed to evaporate at 40°C and the coated filler was subsequently heated at 120°C for 60 min and cooled in airtight containers. The silanated filler was added to the resin mixture in different amounts of 205, 220, 250 and 280 phr. They were mixed well in an agate mortar and pestle till a fine dough-like consistency was achieved. Separate pastes were prepared using particles with different grain sizes.

Compressive strength (CS), diametral tensile strength (DTS) and microhardness (MH) were determined for dental composites prepared by light curing the composite pastes. Specimens of size 3 mm diameter and 6 mm height were made for CS measurements by curing the composite pastes in a brass mould kept between two glass plates and held using a C-clamp. The samples were exposed to a visible light source (440–480 nm wavelength, Caulk the Max, UK) for 60 s each on both sides for curing. Subsequently the samples were released from the mould and the inner surfaces of the cured composite were exposed to the light source for a further 20 s to ensure uniform curing within the core of the material. At least ten specimens of each paste were thus cured and stored at 37°C for 24 h before testing.

DTS specimens of size 6 mm diameter and 3 mm height were prepared similarly using a stainless steel mould. Paste packed in the mould between glass slides were exposed to the same light source as above for 60 s each on both sides for curing. The cured specimens were taken out and stored at 37°C in distilled water for 24 h before testing.

Compressive and diametral tensile strength values were evaluated using a universal testing machine (INSTRON Model 1011, UK) using a reported procedure[8]. The crosshead speed of 10 mm/min was maintained for all testings. At least 6 testings were carried out for each sample and mean and standard deviations calculated. For DTS measurements a minimum of 10 specimens were tested. The load at which break occurred was noted and the CS and DTS values were calculated using the equations

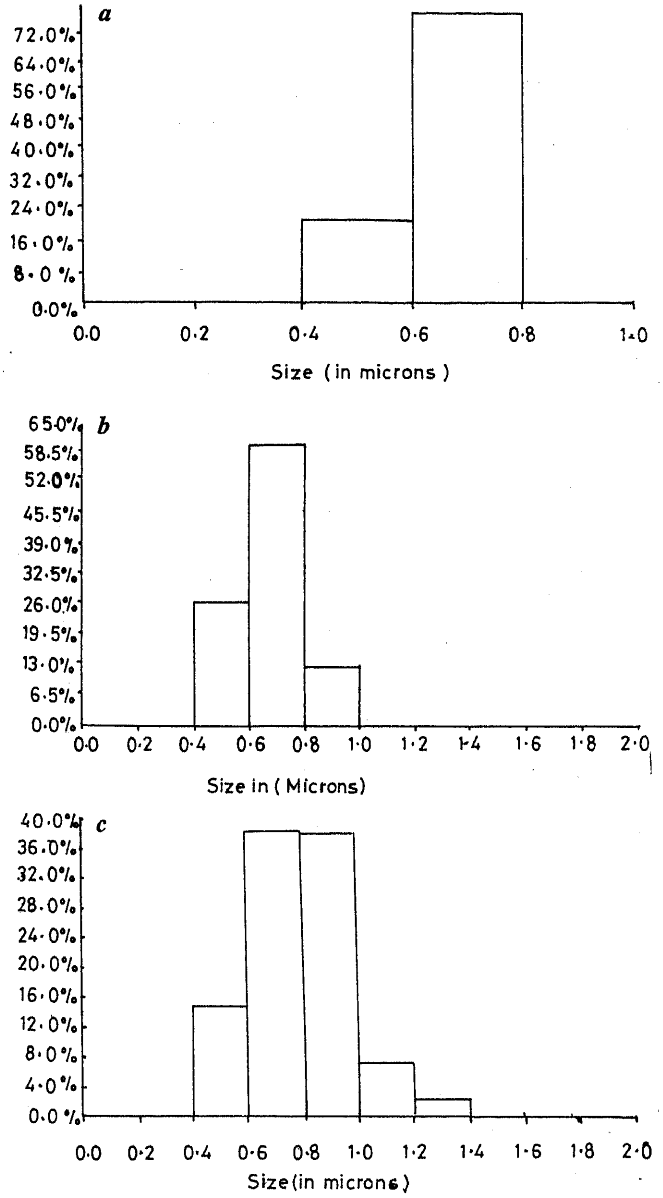

Figure 1. Particle size distribution profiles for glass fillers of grain size 0.7 µm (*a*), 1.0 µm (*b*) and 1.5 µm (*c*).

$$\text{CS (in MPa)} = P/\Pi r^2,$$

where P is the load applied in newtons, r is the radius of the specimen in mm.

$$\text{DTS (in MPa)} = 2P/\pi DL,$$

where D is the diameter of specimen in mm and L is the height of the specimen in mm.

Specimens for surface microhardness were prepared as was done for DTS using the same mould. For each testing, two specimens were used. The surface microhardness was measured on each side using a Vickers microhardness tester (Carl-Zeiss, Jena). At least 8 measurements for each specimen were done and average taken. The diamond indentor fitted is a square-based pyramid suitable for Vickers hardness measurements. The specimen was placed flat on a glass slide and mounted on a holder on the microscope stage. The specimen surface was examined microscopically and the indentor was then moved into position and the microscope stage was raised steadily until the required load was applied by the indentor upon the specimen. In all cases, a load of 100 g was used. The load was held for 15 s before the microscope stage was steadily lowered. The indentor was then replaced with the objective lens and the image of the indentation was focused. The contrast of the image was optimized using differential filtering and the size of the diagonal of the indentation was measured. The Vickers microhardness (H_v) was calculated using the following equation

$$H_v \text{ (in kg/mm}^2) = 1854.4\, P/d^2,$$

where P is the load applied in gram, d is the length of diagonal in microns.

The surfaces of the composites were polished using silicon carbide papers of 240, 400, 600 and 1200 grit, in that order, and finally with 1 µm alumina powder slurry in water, coated with a layer of gold using a vacuum sputtering machine (E-101, Hitachi ion sputter, Japan) and studied using a scanning electron microscope (Hitachi Model S-2400, Japan, 1500–2000 ×).

Particle size analysis of the three glass powders revealed that the grain sizes ranged from 0.7 µm to 1.5 µm (Figures 1 *a–c*). It was found easy to incorporate the filler up to a level of 250 phr into the resin mixture. However, incorporating 280 phr of the filler into the resin was found very difficult especially in case of particles with grain size 1.5 µm resulting in pastes of extremely high viscosity. As a result, the mechanical properties could not be evaluated in this case. Similarly it was observed that the paste formed through mixing 205 phr of the filler was of very low viscosity and it was found difficult to cure samples with the light source due to the flowing characteristics of the paste.

Scanning electron micrographs (Figures 2 *a,b*) show the virgin and composite surface containing glass filler particles. While the virgin filler appears to be agglomerated due to its small size, the filler particles, after silanation, are found encompassed by the resin matrix, which ensures strong bonding at the resin/filler interface. Uniform distribution of filler particles could be observed at the polished composite surface.

Figure 3 shows the compressive strength values for the composite samples prepared using the radiopaque glass filler at different proportions of filler. The recommended values by various standards[9] and in literature[10] for properties of dental composites are given in Table

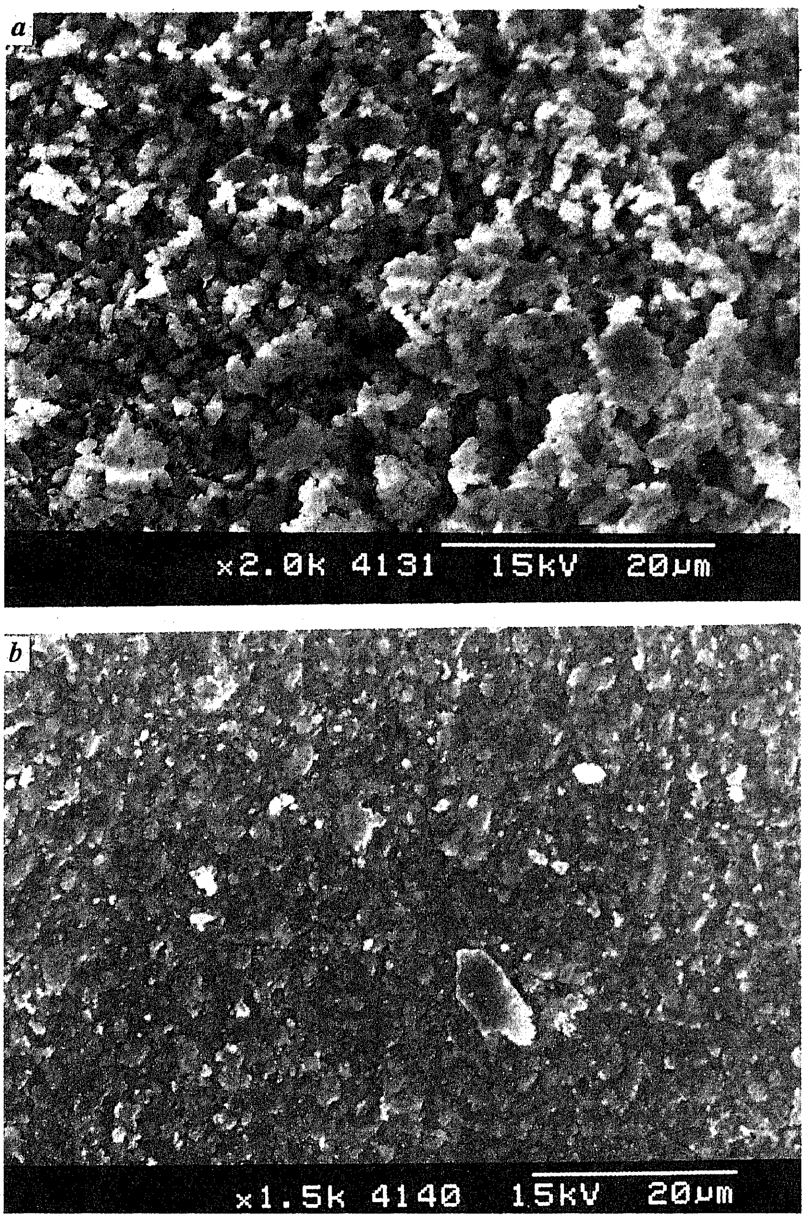

Figure 2. SEM picture of (*a*) virgin filler in agglomerated condition (× 2000) and (*b*) dental composite surface (× 1500) showing uniformly distributed fillers encapsulated with the resin matrix.

Table 1. Comparison of values for properties studied in case of light curing dental composites

Property studied	Recommended value[9,10]	Values obtained using conventional fillers[5]
Compressive strength (MPa)	> 220	220 ± 6*
Diametral tensile strength (MPa)	> 34	36 ± 2
Microhardness (kg/mm^2)	> 34	48 ± 10

*Standard deviation.

1. It can be clearly seen that an amount of 220 phr is found to give excellent CS values in case of particles at all three grain sizes, values reaching up to 300 MPa in certain cases. Higher concentration of filler up to 250 phr though favours composites containing small particles does not seem to agree for particles above 1 µm grain size as is evidenced in the deterioration of the value.

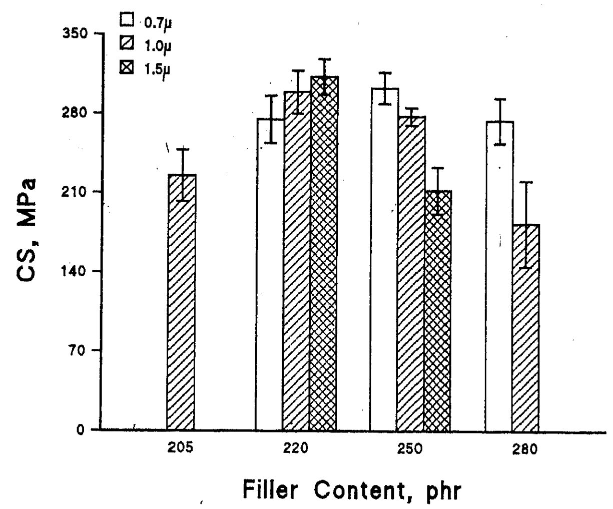

Figure 3. Bar graph showing compressive strength values for composites incorporated with 205, 220, 250 and 280 part per hundred of resin mixture of silanated glass filler GM27884.

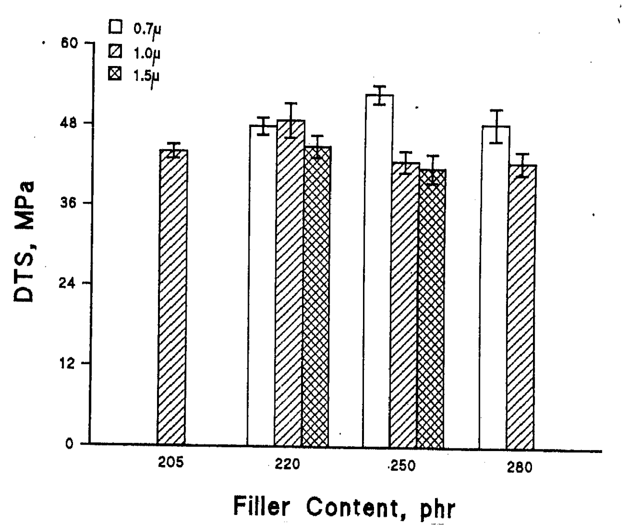

Figure 4. Bar graph showing diametral tensile strength values for composites incorporated with 205, 220, 250 and 280 part per hundred of resin mixture of silanated glass filler GM27884.

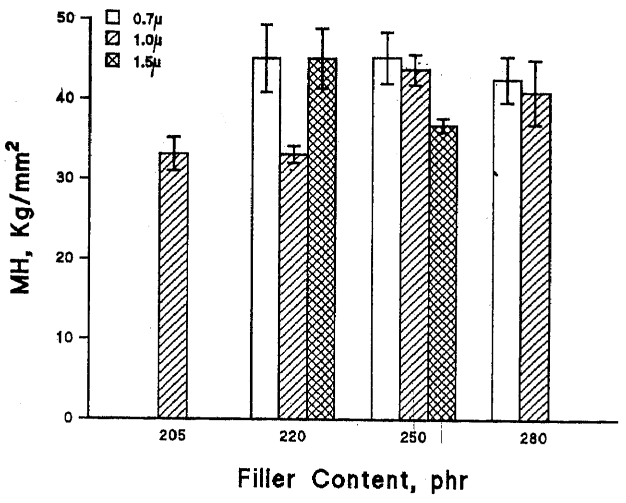

Figure 5. Bar graph showing microhardness values for composites incorporated with 205, 220, 250 and 280 part per hundred of resin mixture of silanated glass filler GM27884.

Observations of DTS values (Figure 4) also showed the same trend for the composite specimens. Dental composites containing 220 phr of the glass filler tended to show excellent strength values in the range of 45–50 MPa whereas the minimum stipulated value is about 34 MPa. As in the case of compressive strength, DTS was maximum for composites containing 250 phr of 0.7 μm grain size particles though with larger particles, properties tended to deteriorate. Microhardness values also tended to show high values (> 45 kg/mm^2) at filler content levels of 220–250 phr.

Finally, incorporation of radiopaque glass filler, especially at 220–250 phr range into the composite is found to improve the above properties when compared to the values obtained for composites containing conventional fillers such as quartz and silica[5] (Table 1). While compressive strength and tensile strength values are found to appreciate, the microhardness values are found to show comparable results. This can be attributed mainly due to the smaller and uniform particle sizes of the glass filler used (0.7–1.0 μm) compared to the larger and non-uniform size of the conventional quartz fillers (1–50 μm) used in the earlier composite.

In conclusion, about 220–250 phr of the radiopaque glass filler GM27884, varying between grain sizes 0.7 and 1.0 μm, when incorporated into the BIS-GMA resin matrix is found to impart better mechanical properties to a light cured dental composite compared to composites containing conventional quartz fillers.

Transpiration in two common tree species of Auroville, Tamil Nadu, India, using the calibrated heat pulse method to measure sap flux

Anil Graves, Pedro Berlinner* and Israel Gev*

Auroville Greenwork Resource Centre, Auroville 605 101, India
*Jacob Blaustein Institute of Desert Research, Sede Baker 84993, Israel

The community of Auroville since 1968 has been reforesting large tracts of land on the Coromandel Coast near Pondicherry. Well over three hundred species of indigenous and exotic trees have been introduced to the area, as well as shrubs, grasses, and creepers. The groundwater has, however, witnessed a steep decline, yet rainfall patterns have not varied out of the ordinary. Although one of the major reasons for this depletion is the huge increase in borewell-irrigated agriculture, it was posited that the reforestation in Auroville must have played some part in modifying the water balance of the area. The purpose of this research therefore, is to understand in more depth, the role of Auroville's forests on the replenishment of groundwater, with a possible view to managing the forests of Auroville according to the requirements of the area's water balance. The technique employed here to determine transpiration is known as 'the calibrated heat pulse method'.

Measurements started in Auroville in March 1994, on two common tree species, *Acacia auriculiformis* and *Peltophorum pterocarpum*. The trees examined were planted in 1982, and the data, taken for five months between March and July 1994, showed that *P. pterocarpum* transpired more than three times as much as *A. auriculiformis*. Although the results were revealing, it was clearly seen that measurements would be required over a period of at least one year, and on more species of trees, to obtain a detailed hydrological picture of the area.

MEASURING the quantity of water transpired by trees has historically been difficult, cumbersome or both, with questionable data to finish with. Such methods have involved weighing the tree and its soil in a weighing lysimeter and measuring the resulting decrease in weight as the tree transpired or, alternatively, injecting dyes, solubles or radioactive materials to be 'traced', thereby giving the velocity of the sap in the tree. The latter methods in particular, physically harmed the tree and even destroyed it, making it alter its transpiration[1], otherwise, as with the lysimeter, trees were taken out of their natural context and estranged from the complex variables that nature brings into play.

The development of the calibrated heat pulse method overcame some of these problems. It involved minimal physical damage to the tree, and the equipment being light and easy to install, could be used in field situations.

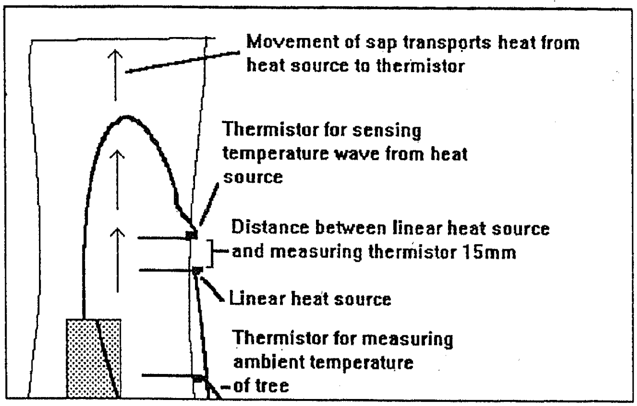
Tracing heat pulses to determine sap velocity was developed by Marshall[1]. He envisaged a two dimensional heat flow in a medium of thermal homogeneity and uniform liquid flux – not likely in a tree, but close enough to reality to make the data valid. Marshall also discovered that the speed of the sap was actually greater than that of the heat pulse and put this down to the disturbance caused by the insertion of thermistors and heater into the tree. Most importantly, what Marshall noted was the constant relationship between the sap velocity and the heat velocity, allowing the difference to be quantified and calculated. Cohen *et al.*[2], who developed the present method using advanced electronic equipment, confirmed this in an experiment on citrus trees, kept under drought and well-watered conditions, in both cloudy and sunny weather. Results showed that the heat pulse method under-estimated transpiration by a mean value of 55.3% with only a 2.4% coefficient of variation.

Research using the calibrated heat pulse method is currently underway in Auroville, Tamil Nadu, India. The project was started after a seminar led to a discussion over the net effect of trees on the hydrology of the area, especially on the level of the water table which was declining steadily despite the extensive watershed work. Auroville, situated on a plateau, now consists of about 2,500 acres of land, approximately half of which has been reforested since the late 1960s.

Due to experimental constraints, only two tree species were measured with four replicates for each species. *A. auriculiformis*, the most dominant tree in the area, is a very fast growing and relatively hardy and drought-resistant exotic from Australia. The other tree selected was *P. pterocarpum*, a popular tree used primarily as an ornamental and alleyway tree.

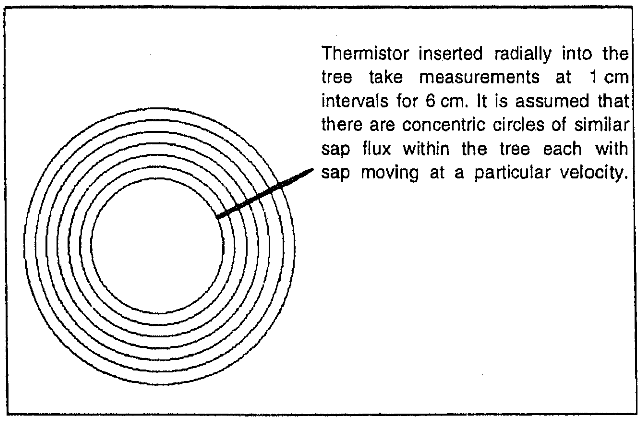
In the calibrated heat pulse method, the heat wave velocity is measured after a half second heat pulse has been radially injected as a line source into the tree. The heat is transported by convection with the sap and measurements of the heat wave velocity are made by special microbead thermistors exactly 15 mm downstream from the linear heat source (that is 15 mm higher up the tree (Figure 1)). Each thermistor is capable of measuring at 1 cm increments into the tree for a total of 6 cm (Figure 2). Programme control and measurement of thermistor signals are made by a datalogger (Campbell 21X) through the intermediary of a custom-built thermistor and heat pulse junction box (Ariel).

As the heat wave passes the thermistors, the time to maximum temperature ($t_{\max}$) is recorded by the datalogger, giving the velocity of the heat between the linear heat source and the thermistor. The $t_{\max}$ values along with the areas of the presumed concentric rings of similar sap flux in the tree (Figure 2) are used in the formula modified by Cohen *et al.*[2] to give volumetric sap flux (for formula see Appendix 1).



Movement of sap transports heat from heat source to thermistor
Thermistor for sensing temperature wave from heat source
Distance between linear heat source and measuring thermistor 15mm
Linear heat source
Thermistor for measuring ambient temperature of tree

Figure 1. Positions of heater and thermistors in relation to sap stream.



Thermistor inserted radially into the tree take measurements at 1 cm intervals for 6 cm. It is assumed that there are concentric circles of similar sap flux within the tree each with sap moving at a particular velocity.

Figure 2. Presumed concentric rings of sap flux movement inside the tree.

When illustrated, the t_{max} values indicate how the tree responds to its environment. Figures 3 and 4 illustrate t_{max} values for *P. pterocarpum* and *A. auriculiformis* respectively, during March 1994. *P. pterocarpum* (Figure 3) responds very rapidly to the onset of light, almost reaching its maximum sap flux in two hours. In addition, all six microbead thermistors register a response. This indicates that sap flux occurs to a depth of 6 cm, possibly more, and that sap flux for all 6 concentric rings must therefore be calculated. A lateral cut through *P. pterocarpum* shows it to be largely composed of sapwood and confirms that sap flux can occur in all the 6 concentric rings that are measured.

A. auriculiformis (Figure 4) responds differently to *P. pterocarpum*. Its t_{max} graph indicates that only the two outermost rings of the tree are conveying sap as indicated by thermistors 1 and 2. This is again evident from a cross-section of the tree, which is largely composed of heartwood, apart from the exterior 1 or 2 cm. The t_{max} values indicate lower sap velocity and the curves are less pronounced. For these reasons it can be expected that *A. auriculiformis* transpires less than *P. pterocarpum.*

The t_{max} values indicate which rings of the tree transpire and during which hours of the day they transpire. Having determined this, it is possible to calculate the volumetric flow of sap in the tree. Sap flux in *P. peltophorum* starts rather abruptly from 0.7 litres between 7.25 h and 8.25 h to 7.2 litres between 8.25 h and 9.25 h (Figure 5). Maximum sap flux occurs between 13.25 h and 14.25 h and is about 12.4 litres. The outermost ring monitored by thermistor 1 conveys the most water during the day (21.8 litres), whilst thermistors 5 and 6 monitoring the innermost rings of the tree show similar sap fluxes of 5.5 and 5.7 litres per day. The total sap flux on March 14 is about 84.6 litres.

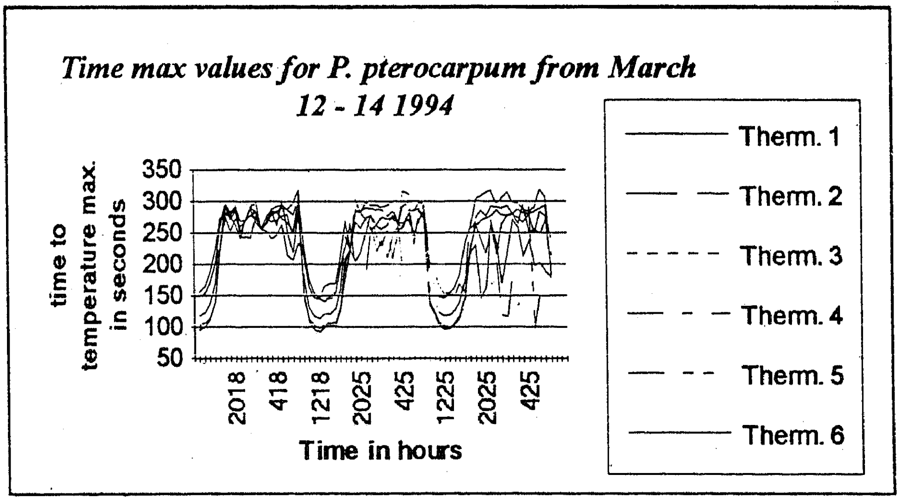


Figure 3. t_{max} values for *P. pterocarpum* in March 1994.

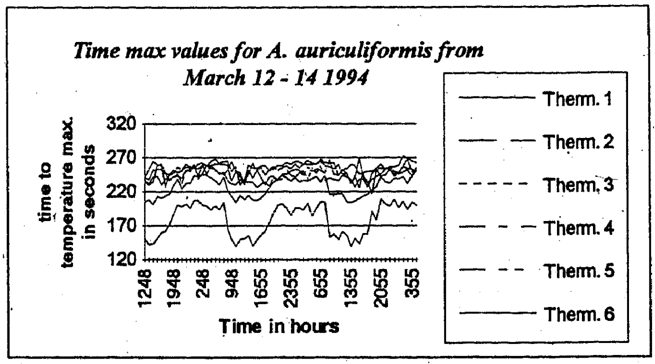

Figure 4. t_{max} values for *A. auriculiformis* in March 1994.

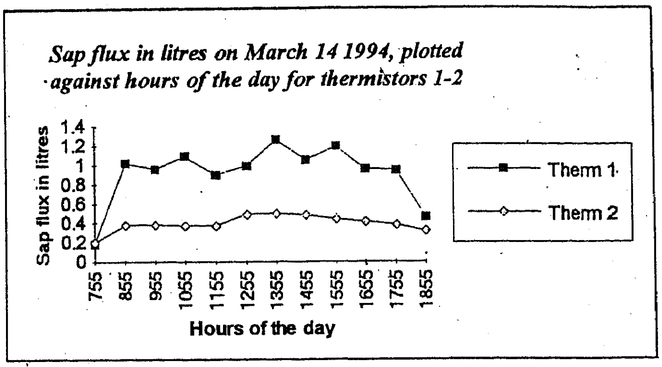

Figure 6. Sap flux for *A. auriculiformis* on March 14, 1994.

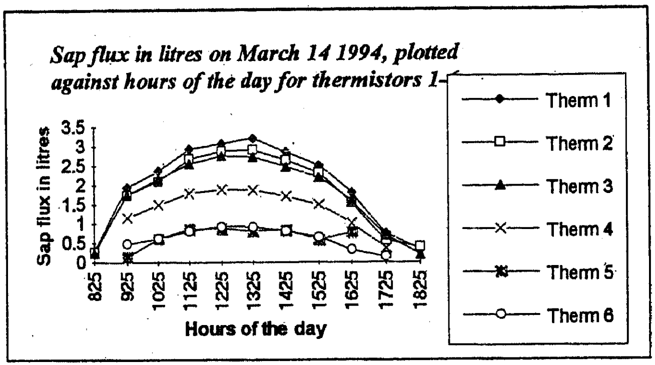

Figure 5. Sap flux for *P. pterocarpum* on March 14, 1994.

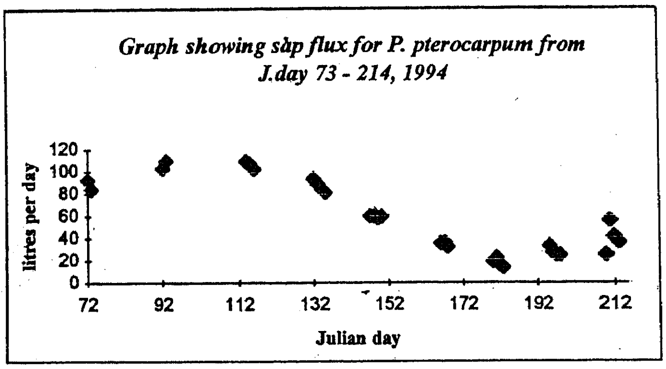

Figure 7. Sap flux for *P. pterocarpum* between March and July 1994. Each square indicates daily sap flux.

The case is rather different for *A. auriculiformis* (Figure 6) as only the 1st and 2nd thermistors indicate sap flux. The 4 inner rings show 'diffusivity' (the movement of heat through the woody material, without convective transport by sap) and indicate zero or very low sap flux. The calculations for sap flux therefore need to be made only for the outer 2 rings monitored by the 1st and 2nd microbead thermistors. It is evident that in *A. auriculiformis*, sap velocity is much lower than in *P. pterocarpum*. The curve is correspondingly less pronounced, showing that it is less responsive to light. Sap flux commences at about 7.55 h and during the first hour is about 0.9 litres. It reaches a maximum of 1.9 litres between 13.55 h and 14.55 h, declining to a stop at about 18.55 h. Total sap flux for 24 hours is about 16 litres.

The presence or absence of sunlight stimulates sap flux, particularly in *P. peltophorum* which is literally 'switched' on and off by sunlight, exhibiting a strong biological rhythm. Other variables, however, are also important in influencing sap flux, notably soil moisture and the physiological status of the tree (i.e. whether it is in leaf or bare).

Figures 7 and 8 show total daily sap fluxes for *P. pterocarpum* and *A. auriculiformis*, from mid March to July (Julian days 73–214). In *P. pterocarpum* (Figure 7) sap flux increases from about 85 litres per day in mid March (Julian day 73) to about 110 litres per day by the latter half of April (Julian day 112). This is partially attributable to increasing leaf cover density (*P. pterocarpum* loses its leaves between December and February, but by February, March and April is in the process of leafing again), and the greater transpirative surface that is thereby created. Additionally, transpirative demand is also increased, as summer progresses and net radiation and dry bulb temperature rise. Sap flux therefore increases to whatever extent is permitted by the level of moisture in the soil. Thereafter total daily sap flux declines steadily due to decreasing soil moisture, as the rainless days of summer progress and the available soil moisture evaporates, percolates or is transpired by the tree. By the end of June (Julian day 181), sap flux is reduced to about 15 litres per day. After this, it starts to increase again, as the first rains of the SW summer monsoon augment soil moisture.

The pattern is different for *A. auriculiformis* (Figure 8). As the tree is almost evergreen, there is little influence of increasing leaf density on sap flux. Instead, there is a steady decline from 14 litres per day in mid March (Julian day 72), to about 4 litres per day by the end of April (Julian day 112), as soil moisture brought by the 1993 NE winter monsoon declines. This basic level of sap flux remains unaffected by the first showers of the 1994 SW monsoon that started on Julian day 160.

Figures 9 and 10 show how these two trees respond to a sudden increase in soil moisture caused by an 11 mm rainfall at about 21.00 h on Julian day 210 (July 29). The $t_{\max}$ values for *P. pterocarpum* (Figure 9) on Julian day 210 before the rain falls, indicate maximum sap velocity at 14.03 h with a minimum $t_{\max}$ value of 166 sec. After the rain, the $t_{\max}$ values on Julian day 211 decrease from 166 sec to 122 sec at 12.09 h on Julian day 211, indicating a dramatic increase in the velocity of the sap. Of further note is that the 5th and 6th thermistors (5 and 6 cm deep) do not indicate sap flux during Julian day 210. However, the rain on Julian day 210 allows the 5th thermistor to start conveying sap once again on Julian days 211 and 212. (Note that during March when soil moisture was high, all 6 thermistors were indicating sap flux (Figure 3).) The decrease in $t_{\max}$ values at 21.06 h on Julian day 210 indicates that the tree might have absorbed water at night and that some sap flux is perhaps taking place although there is no transpiration. This may be due to an increase in the soil moisture potential after the rainfall, which has allowed water to move into the tree. The effect of the rain is short lived, as a steady decrease in sap flux is indicated by the increasing $t_{\max}$ values for Julian days 212 and 213. By Julian day 213, the 5th thermistor once again indicates absence of sap flux altogether.

A. auriculiformis (Figure 10), on the other hand, shows no such response to the rainfall on Julian day 210. Only the first thermistor shows a slight decrease in $t_{\max}$ values from around 180 sec on Julian day 210, to about 175 sec on Julian day 211, almost negligible when sap flux is calculated. The $t_{\max}$ values seem to show that sap flux is altogether absent, with only thermal 'diffusivity' occurring. Calculations with these values, however, still indicate small quantities of sap flux (Figure 8).

It should be emphasized that the discussion above revolves around only 2 of the 8 trees studied (1 for each species), and that intra-species $t_{\max}$ values (and thus intra-species sap fluxes) are not necessarily identical to the two examples used. This is illustrated in Table 1 which summarizes the total monthly sap fluxes (in litres) of all four *A. auriculiformis* and all four *P. pterocarpum* monitored between March and July 1994. The trees examined in the discussion above are indicated in the table as Aa3 and Pp3. The average sap flux for *P. pterocarpum* over the 5 months of measurements comes to 8.1 m^3, whilst for *A. auriculiformis*, average sap flux over 5 months comes to 2.3 m^3.

From the data in Table 1, it is evident that all four *A. auriculiformis* together transpired about 9.4 m^3 of water between March and July 1994, whilst all four *P. pterocarpum* together transpired about 32.6 m^3 of water over the same period. Rainfall in Auroville in 1994 was 1.15 m^3 per m^2. Sap flux between March and July for *A. auriculiformis* as a percentage of the rainfall received

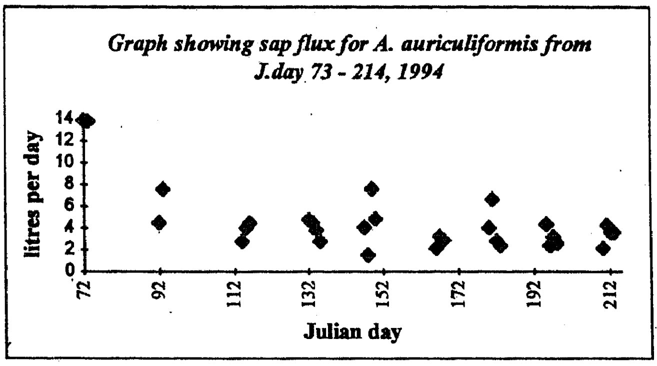

Figure 8. Sap flux for *A. auriculiformis* between March and July 1994.

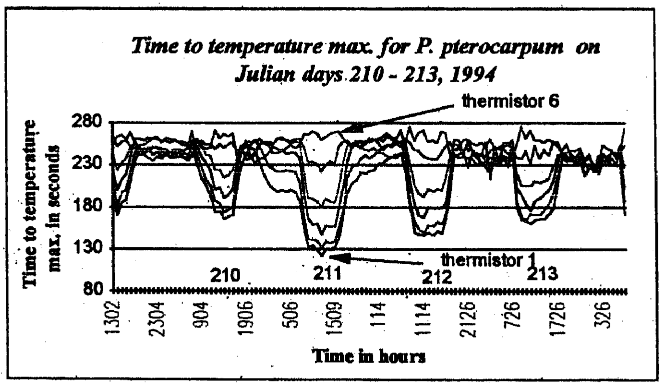

Figure 9. $t_{\max}$ values for *P. pterocarpum* in July 1994.

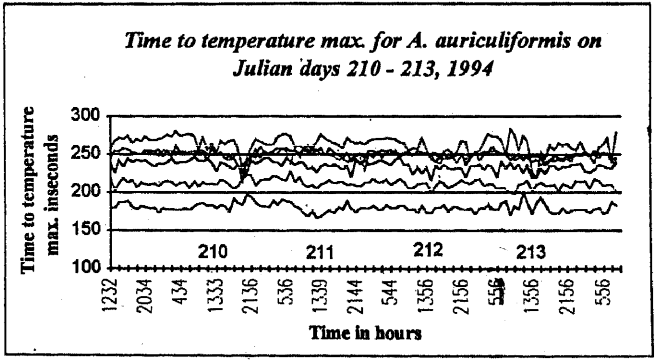

Figure 10. $t_{\max}$ values for *A. auriculiformis* in July 1994.

Table 1. Total monthly sap fluxes for the eight trees monitored between March and July 1994

Tree no.	March (in litres)	April (in litres)	May (in litres)	June (in litres)	July (in litres)	For 5 months (in m^3)
Aal	597	511	398	186	159	1.85
Aa2	745	753	321	381	237	2.44
Aa3	705	429	405	306	189	2.05
Aa4	1334	954	300	291	159	3.04
Average	845	662	356	291	186	2.34
Pp1	1338	2192	1326	1326	1329	7.82
Pp2	450	938	750	282	264	2.68
Pp3	2751	3568	2625	720	912	10.58
Pp4	1410	3128	3045	1701	2198	11.48
Average	1487	2457	1937	1007	1176	8.14

upon the canopy area of all eight trees (276 m^2) is therefore about 2.9%. For *P. pterocarpum* the figure is about 10.4%. During the five-month study, the eight trees together transpired about 13.3% of the rainfall that fell upon their canopies in 1994.

Assuming that the seven unmeasured months might give equivalent values, these eight trees would, during 1994, transpire 31.1% of the rainfall falling on their canopies. This figure is naturally unrealistic. *P. pterocarpum*, for example, sheds its leaves during winter putting a stop to transpiration altogether, whilst soil moisture and transpirative demand undergo extensive changes during the monsoons.

As runoff from the research plot is minimal, it can be assumed that the 68.9% of the rain not transpired by the trees infiltrates into the soil and percolates. What proportion of this reaches groundwater and what proportion of this is evaporated directly from the soil or is transpired by understorey vegetation remains to be seen.

Attempts to quantify the hydrological impact of reforestation in Auroville on the water balance of the local soil and groundwater should ideally include measuring runoff and evaporation from 'bare' as well as reforested areas. It is also important to evaluate with advanced research methods, what proportion of the sap flux comes directly from groundwater sources and what proportion of it comes from soil moisture[3].

In conclusion, the study has allowed sap fluxes in two tree species, *P. pterocarpum* and *A. auriculiformis*, to be quantified, showing that sap flux in *P. pterocarpum* is significantly higher than in *A. auriculiformis* (Table 1). Changes in daily sap flux between March and July 1994, were evident for both *P. pterocarpum* (Figure 7) and *A. auriculiformis* (Figure 8). In *P. pterocarpum* the onset of the SW monsoons stimulated an increase in sap flux. In *A. auriculiformis* no such response occurred presumably because the necessary soil moisture level had not yet been attained by the time measurements ended in July.

To some extent the study has also unveiled the inner dynamics of water movement in *P. pterocarpum* and *A. auriculiformis*. When soil moisture was plentiful, sap flux in *P. pterocarpum* occurred to a depth of 6 cm (Figure 3) and in all 6 concentric rings (Figure 2), whilst in *A. auriculiformis* sap flux occurred to a depth of only 2 cm (Figure 4) and was confined to the outer 2 concentric rings (Figure 2). This pattern changed as soil moisture decreased during the rainless summer months. In *P. pterocarpum*, sap flux stopped in the 2 innermost concentric rings and occurred in only the 4 outermost concentric rings (Figure 9). In *A. auriculiformis*, only thermal 'diffusivity' in the 2 outer sap conveying rings occurred during the dry summer months (Figure 10), indicating that ideally more sensitive equipment is needed to measure sap flux at such low velocities.

With further research on other tree species, it will be possible to know how reforestation as a land use compares with agricultural or domestic land use, or with just leaving the ground bare. In particular, it will be possible to know which trees and how many trees to introduce into which hydrological situations. In an area with scarce water resources for example, it might be more beneficial to introduce trees which are frugal users of water, like *A. auriculiformis*, whilst trees with high transpirative capabilities like *P. pterocarpum* might be better utilized in areas prone to water logging. Concerning Auroville and coastal areas in general, where urbanization and population are rapidly increasing and salt water intrusion and falling groundwater levels threaten to bring environmental catastrophe, trees selected for their transpirative characteristics and planted in strategically chosen areas could do much to redress the hydrological balance.

Appendix 1

Marshall's formula as modified by Cohen *et al.*[2] is quoted below:

'The temperature elevation, T, produced by the heat pulse after time, t, and at a distance $r = (x^2 + y^2)^{0.5}$ from the line heater, is given by (Marshall[1]).

$$T = H/4\pi pckt \, \exp((x-Vt)^2 + y^2)/4kt, \qquad (1)$$

where H is the heat output per unit length of the heater, and p, c, and k are the density, specific heat, and the thermal diffusivity of wet wood, respectively. The heat wave convective velocity, V, is defined as:

$$V = (p_1 c_1 / pc) J_1 \, . \qquad (2)$$

The function defined by equation (1) has a maximum occurring at $t_{\max}$ when the first derivative of eq. (1) is equal to zero. This condition yields,

$$V=(r^2-4kt_{\max})^{0.5}/t_{\max}. \quad (3)$$

For a given value of r, and with known physical and thermal properties of the live wood, the measurement of $t_{\max}$ in eq. (3) allows the computation of the water flux J_1, in eq. (2). The only property that is difficult to determine is the thermal diffusivity, k of the live wood. With $V=0$, eq. (3) yields,

$$k=r^2/4t_{\max}. \quad (4)$$

Consequently, k can be determined when no convective transport is taking place. In order to determine the volumetric flow, F, the water flux, J_1 must be integrated over the cross-sectional area of the stem,

$$F=\int J_1 ds, \quad (5)$$

where ds is the element of stem area in which J_l has been determined.'

Bioleaching of copper from chalcopyrite ores coated with polyaniline film

S. A. Mallick* and A. K. Dasgupta**

Regional Agriculture Research Section, S.K. University of Agricultural Sciences and Technology, R. S. Pura, Jammu Tawi 181 102, India
**Department of Biochemistry and Biophysics, University of Kalyani, Kalyani 741 235, India

A simple method of extracting copper and iron from chalcopyrite ore using the bacterium *Thiobacillus ferrooxidans* is reported. By surface modification of the ore and using a thin polyaniline film, the rate of bioleaching can be increased considerably. The film acts as a coating to the heterogeneous ore surface, leaving the catalysable sites more frequently exposed to microbial attack. The inhibitory effect is due to formation of jarosites, and is found reduced in the coated ore samples. This may be due to ferric hydroxide formed within the film coat during leaching.

SEVERAL reports pertaining to improvement of bioleaching process have appeared in the literature. The effect of detergents[1,2] and passing of mild electric current[3,4] etc. have been reported to be beneficial for the recovery process. On the other hand, the adverse effect of detergents[5] has also been reported. Leaching primarily involves a direct pathway[6–9], wherein *Thiobacillus ferrooxidans* attacks the ore mineral causing leaching. Thus an alteration of the ore–bacteria interface would affect leaching rate either positively or negatively. Murr and Berry[10] observed no preferential adhesion of cells of *T. ferrooxidans* to specific surface features such as steps or dislocations, needed both for molybdenum sulphide and chalcopyrite. However, higher growth rate was observed at the inclusions. As the surface of the ore dictates the rate-determining factors of leaching, in the present work premise the dislocation sites were artificially exposed to microbial attack. Another reason for following this procedure was that gangue material containing oxides of magnesium, calcium and aluminium may be inaccessible to microbial populations, and by preventing the catalytically inactive growth, one could arrest the extent of precipitation of jarosites (precipitation of ferric hydroxide complex associated with growth of *T. ferrooxidans*).

The microorganism, *T. ferrooxidans*, is a chemolithotrophic bacteria deriving its energy from ferrous oxidation reaction utilizing carbon dioxide as the main carbon source. The strain of *T. ferrooxidans* in ATCC19859d (supplied by Dr David Holmes, USA) was repeatedly subcultured in 9 k medium[11] (ammonium sulphate, 3 g;

Table 1. Composition (proportion-wise) of polyaniline coated chalcopyrite ore samples

Sample	Aniline (M)	Ammonium persulphate (M)	Chalcopyrite ore (g)
1	0.1	0.73000	0.5
2	0.1	0.07300	0.5
3	0.1	0.00073	0.5

potassium chloride, 100 mg; dipotassium hydrogen phosphate, 500 mg; magnesium sulphate, 500 mg; with pH adjusted to 1.8 + 30 g ferrous sulphate added to it, and the pH adjusted to 2.0). The ore sample, chalcopyrite concentrate, was a gift from M/s Hindustan Copper Ltd.

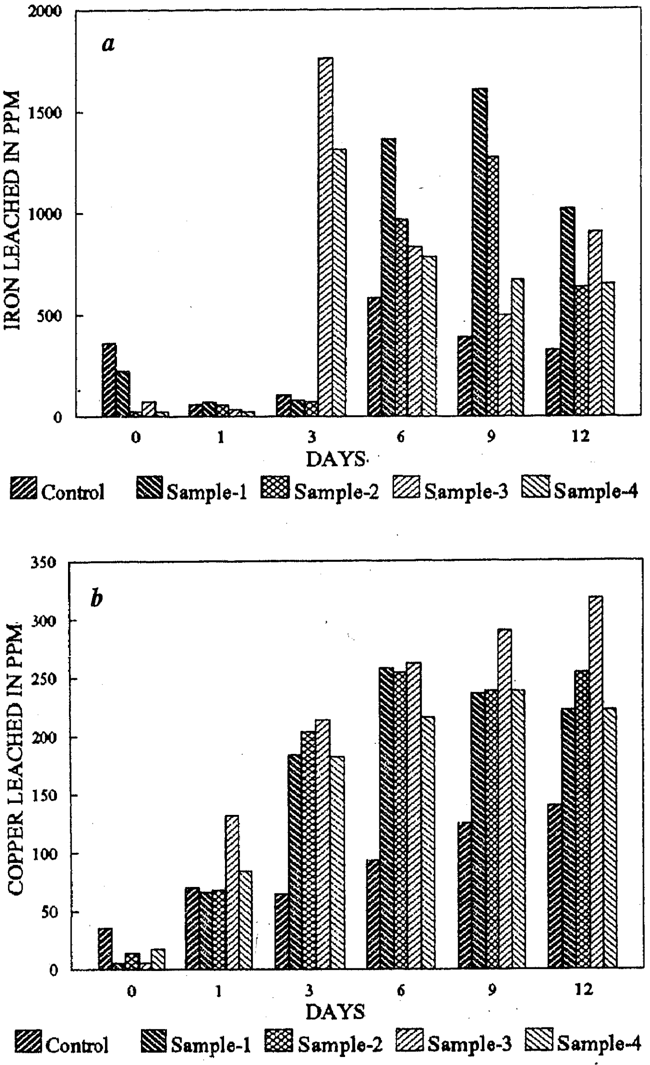

Figure 1. Comparative amounts of leaching of iron (*a*) and copper (*b*) from polymer coated and uncoated chalcopyrite ore samples up to 12 days of studies. Polymer-coated sample 3 is found most suitable, releasing maximum amount of iron (3rd day) and copper (12th day). All other polymer-coated samples also have higher efficiency of leaching metals than that of control.

Leaching was studied using 100 mg of cell concentrate obtained from well grown culture of *T. ferrooxidans* at pH 2.0 and 1 g of ore/sample (surface modified ore). The procedure was then repeated by adding 9 k medium instead of the cell culture. The samples were subjected to continuous shaking for optimal aeration at 30°C in a tissue culture shaker at 12 rpm.

For the assay of copper and iron, 0.5 ml of aliquots was collected at 24 h intervals and subjected to centrifugation at 7000 rpm for 10 min at room temperature using a Remi microfuge. The pellet was discarded and the supernatent diluted 200 times for measurement in

an atomic absorption spectrophotometer (model: Varian AA-1475). For reliable measurements five replica samples were taken for each aliquot and both the iron and copper concentrations were measured.

The ore surface was modified by depositing a thin film of polyaniline polymer. The thickness of the film was varied by adjusting the concentration of the oxidant (ammonium persulphate) and the monomer (aniline). In each case the system was allowed to reach equilibrium. The ore coated with the polymer was filtered and washed with distilled water. The dried sample was then tested for leaching. The four different samples were obtained by varying the relative concentrations of the oxidant and the monomer (see Table 1). The leaching experiment was performed with the aforesaid samples and the original ore.

A comparison of leaching of copper and iron both in the polymer-coated ore samples and in the uncoated ore samples in their naive form is shown in Figures 1 and 2. As can be seen, the polymer-coated samples leach copper at a faster rate. To prevent possible errors resulting from the heterogeneous nature of the different fractions of the ore samples, the kinetic profile was normalized taking five replicas from aliquotes of each sample at each day point. The percentage error in the measurement is shown by the bar diagram (Figure 3 *a* and *b*). As described earlier, leaching from each of the samples was studied both in the presence of and absence of *T. ferrooxidans*. Leaching of Cu from the polymer-coated samples was always higher in the presence of bacteria (Figure 1), indicating that microbial attack was possible despite the presence of polymer coating and that the enhanced leaching observed was not entirely due to alteration of the chemical leaching profile.

Figure 1 shows the iron-leaching profile of the original ore sample and that coated with polymer. As is seen, for samples coated with the polyaniline, the solution affinity for iron is higher in the initial stage (3–5 days) but falls subsequently. Figure 1 is a typical example of how the leaching of Cu and Fe took place from polymer-coated ore sample.

In all the four ore samples coated with polymer, leaching of copper and iron was higher in the presence of *T. ferrooxidans* compared to control samples (without bacteria). This indicated that biocatalysis operates even in polymer-coated states. Figures 1–3 also illustrate the time profiles of copper and iron respectively appearing in the solution. It is clear that leaching rate was higher for polymer-coated chalcopyrite samples compared to that of uncoated sample. The recovery of copper recorded every day was steady for each coated sample, whereas iron underwent fluctuations during leaching. This was due to precipitation of ferric hydroxide as jarosite. Among the polymer-coated samples, sample 3 was found more effective in both the categories of metal leaching (Table 2). This suggested that for sample 3, coating by polymer helped in maximum recovery. In the initial phase of experiment, due to direct leaching by concentrated sulphuric acid, the uncoated ore sample (control) always had higher concentration of copper or iron compared to that of any polymer-coated sample. Comparative results of leaching on the first two days show that sample 3 was completely free from acid leaching, thus proving that polymer coating of sample 3 was complete and assisted in better leaching. The composition of polyaniline polymer (Table 1) indicates that a thin film of polyaniline polymer covering the whole chalcopyrite ore particle might be most suitable for effective bacterial attack on the coated ore sample. It prevents ferric hydroxide precipitation and other metabolites which could cause a change in the constituents and conditions of medium acting as a deterrant in the growth of bacteria or leaching of the metal.

A number of surface-reacting agents presently being used for improvement of leaching have shown a negative effect on the bacteria. The present technique which involved modification of ore surface by covering the ore by a polyaniline film enables the organism to attack the encapsulated ore and ensures the protection of unwanted metabolites from interfering in the composition of the medium by stopping leakages through the polymer film. Unlike the surface reacting agents, this method is useful to all micro-organisms.

On the occurrence of manganese micronodules in the deep-sea sediment west of Lakshadweep Ridge, Arabian Sea

K. S. Adiga and V. K. K. Kalluraya

Geological Survey of India, PKV Bhanderkaras Complex, Mannagudda, Mangalore 565 007, India

Sediment cores collected from the eastern Arabian Sea, west of Lakshadweep Ridge at water depths of 2800–4400 m, have indicated the presence of manganese micronodules over an area of 0.08 million sq km. These nodules occur sparsely in the sediments between 10 and 50 cm below the seafloor. The host sediment is composed of brown to dark brown pelagic clay of 5 to 20 cm thick. The nodules occur as thin coatings and infillings of Mn-hydroxide mainly over planktonic foraminiferal tests. The micronodules do not exceed 0.5% by weight of the host sediment but are abundant in the coarse fraction (> 53 μm), constituting 2.6 to 24%. Birnessite is the main Mn-hydroxide mineral in the nodule. Chemical data suggest that micronodules are Mn-rich, and are generally Fe-depleted with Mn/Fe ratio varying between 4.76 and 80. Micronodules have highly variable trace element concentrations. In contrast to micronodules of Central Indian Basin, the present nodules are depleted in trace elements, though both have more or less comparable Fe–Mn abundance.

Occurrence of ferromanganese micronodules in surface and sub-surface sediments has been described from both marine and lacustrine regimes the world over. The formation of both macro and micronodules demands several favourable conditions such as low sedimentation rate, an oxidizing environment, presence of nucleating material, influence of microbiotic activity and the availability of elements for precipitation from lithogenous component and/or pore water. These conditions facilitate the growth of colloidal aggregates of Mn–Fe oxides and hydroxides ranging from microscopic specks to macroscopic concretions[1]. While authigenising Mn and Fe, the nodules also incorporate traces of Ni, Cu, Co, Pb, Zn, noble metals, elements of platinum group and REE.

The basic difference between manganese macro- and micronodule is their size; the latter is commonly smaller than 1 mm and the former can be as large as a few cm (ref. 2). Micronodules from the Pacific are relatively well documented. The distribution of Fe, Mn, Cu, Ni and Co in coexisting Mn-nodules and micronodules from the world's oceans indicates that in about 60% of the coexisting pairs, micronodules are found to show relatively low Ni, Co and Cu and a low Mn/Fe ratio[3]. The morphology characteristics[4] and geochemistry[5–7] of micronodules from the Pacific have been extensively studied. Micronodules of the Central Indian Basin (CIB) have also been studied in recent years. Their distribution, morphology and geochemistry have been dealt by many workers[8–10]. Occurrence of micronodules has been recently reported from Bay of Bengal also[11,12].

The present work is based on preliminary studies of core samples collected from the western part of the Lakshadweep Ridge (LR) during cruises of *RV Samudra Manthan* (RVSM) of the Geological Survey of India between 1986 and 1993. Many of these cores collected from depths of 2800–4400 m have indicated the presence of manganese micronodules in the sub-bottom sediment layer. This layer is composed of brown to dark brown pelagic clay and forms the host sediment. Possibly this is the first report of the occurrence of micronodules from this part of Arabian Sea. The objective of the paper is to present basic data on mode of occurrence, morphology and geochemistry of these micronodules and discuss their probable origin.

Sub-bottom samples of 27 RVSM gravity and piston cores (Figure 1) were partly used for the present study. About 25–30 g of the host sediment was treated with 50 ml of 15% H_2O_2 for 15–20 min to rapidly separate the micronodules from the matrix. MnO_2 of the sediment being a natural catalyst splits H_2O_2 into H_2O and O_2 (ref. 13). The reaction is exothermic and the intensity of heat and fumes generated is an indication of the abundance of micronodules in the sediment. After gently stirring and washing, the slurry was wet-sieved using + 230/270 ASTM sieve to separate the coarse fraction,

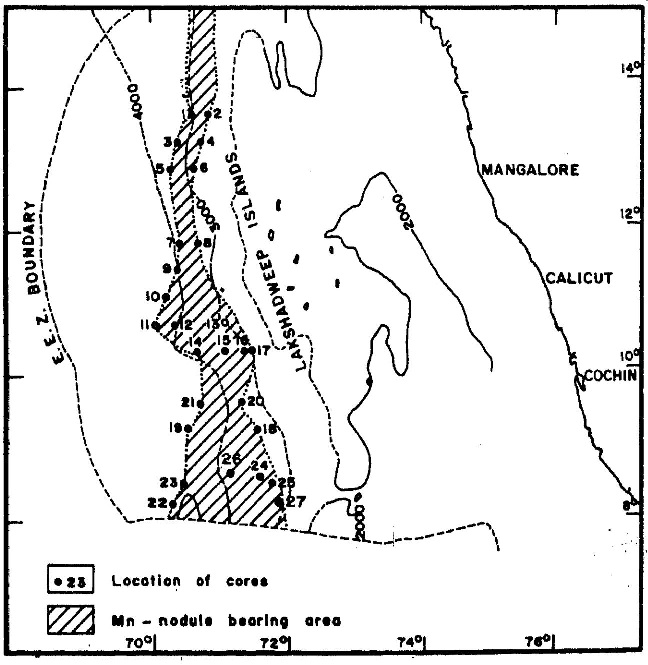

Figure 1. Map of the eastern Arabian Sea showing manganese micronodule-bearing area with locations of gravity cores.

which was dried, and then treated with 20 ml of 10% acetic acid for 10–15 min to remove the uncoated carbonate tests. The concentrate thus obtained was dried, weighed and examined under microscope to find the non-carbonate impurities. In few cases, the coarse fraction was subjected to heavy liquid separation using bromoform (sp. gr. 2.8). The thinly or partially coated micronodules floating in the heavy liquid were collected to study their morphology. Siliceous tests and detrital minerals in the concentrate were less than 1%.

The chemical analysis was carried out on 12 out of 27 concentrates. About 0.1 g of the concentrate was treated with 5 ml aqua-regia and then with 1 ml of 40% HF. The solution was gently evaporated to dryness and 5 ml of concentrated HCl was added and again heated to dryness. After another addition of 5 ml of 1 : 1 HCl, the solution was gently warmed. Mn, Cu, Pb, Zn, Ni and Co were determined using AAS (Varian Spectr. AA 30) in air–acetylene flame whereas Fe was determined in nitrous oxide–acetylene flame. Necessary dilutions were made before feeding the solution into AAS. Calibration standards used were prepared from recommended metals/salts.

X-ray diffraction of one nodule sample (core no. 5057; location 26 in Figure 1) was carried out on Phillips APD refractometer using CuK$_\alpha$ radiation to know the mineralogical components of the nodule. Results were cross-checked using FeK$_\alpha$ radiation.

The micronodules are distributed over a length of approximately 800 km between 8° and 15°N latitudes and 69° and 72°E longitudes. The area of their distribution is narrow (~ 45 km) in the north but gradually widens towards south (~ 380 km) covering nearly 0.08 million sq km of the eastern Arabian Sea (Figure 1). The middle and lower parts of the slope and the areas fringing the abyssal plain show greater abundance of nodules.

Mn-micronodules occur at depths 10–50 cm below sea bed. The host sediment varies in thickness from 5 to 20 cm and is a distinct layer of brown to dark brown (10YR 5/3–4/3) pelagic clay. It occurs between pale brown hemipelagic clay above and olive grey calcareous ooze/hemipelagic clay below, indicating respectively oxic and reducing conditions. Preliminary studies reveal that the micronodules constitute not more than 0.5% by weight of the host sediment, but they are abundant in the coarse fraction (> 0.05 mm), constituting 2.6 to 24%. Interestingly, one core (No. 5050, location 27 in Figure 1) from far-south reveals the presence of fossil Mn-oxidation front even below 50 cm level. The litholog of a representative core (No. 2631, location 15 in Figure 1) from the central part is given in Figure 2.

The micronodules occur as jet black to brownish black coatings and infillings essentially over microforaminiferal tests, less commonly over skeletal tests of pteropods and radiolarians and rarely over glass shards. Authigenic coating over planktonic tests is the most dominant type. The nodules display spheroidal, elongated, botryoidal, tubular or pseudo-framboidal morphologies and commonly retain the shape of skeletal tests or substrate (Figure 3). Their size is generally < 0.25 mm, but larger ones are not infrequent. Pteropod-coated nodules can be even 2 mm long. Partial or incipient coating of the nucleii is seen more in the northern part of the area. The surface texture of the micronodules is characterized by irregular, gritty and at times smooth and polished appearance with bright lustre. Growth of secondary minerals over the nodule often masks its colour and texture.

XRD result suggests birnessite as the major mineral phase in the present micronodule. This is the intermediate variety of the common manganese hydroxides in Mn-nodules and normally forms under suboxic condition. Associated minerals detected are quartz, feldspar, chlorite and illite.

Chemical data of 12 samples are given in Table 1. The data suggest that Mn content is high, varying between 25.10 and 43.0% with an average of 35.83%. Fe varies from 0.53 to 5.27% with an average of 1.82%. The Mn/Fe ratio varies considerably from 4.76 to 80 with an average of 31.10. The trace element content is as follows; Cu: 178–1,100 ppm, Ni: 20–2,000 ppm, Zn: 28–350 ppm, Co: 10–300 ppm and Pb: 40–1,600 ppm. In general, higher Mn values are recorded from deeper areas. The chemistry of the present occurrence and that

of other known occurrences are given in Table 2 for comparison. Micronodules of the present area are broadly comparable to CIB micronodules in their Mn and Fe contents and Mn/Fe ratio. The trace element values in the latter[2], however, are significantly higher and the former is highly depleted of the same. In relation to the micronodules of Bay of Bengal[11,12], the present nodules have higher Mn and comparable Fe, Ni and Co contents.

Marine Mn-mineralization is controlled by three accretionary modes[11,12], viz. hydrogenous precipitation, oxic diagenesis and suboxic diagenesis. Triangular plots of Mn, Fe and (Cu + Ni + Co) × 10 contents of macro/micronodules have been used to delineate the environments of nodule precipitation[14,15,11]. The micronodules and Mn-coating of the present area fall within the suboxic environment (Figure 4). This is corroborated further by the disposition of the host sediment between lithologies indicative of oxic and reducing conditions. Similar sediments, with light coloured brown units above and olive coloured units below showing sharp colour boundary suggestive of an active oxidation front, have also been reported from the Madeira Abyssal Plain, N. Atlantic[16]. Brown colours in pelagites are commonly produced by concentrations of manganese hydroxides[17]. Higher Mn/Fe ratio implies an early diagenetic effect on nodule growth[2,9]. A transition from reducing condition

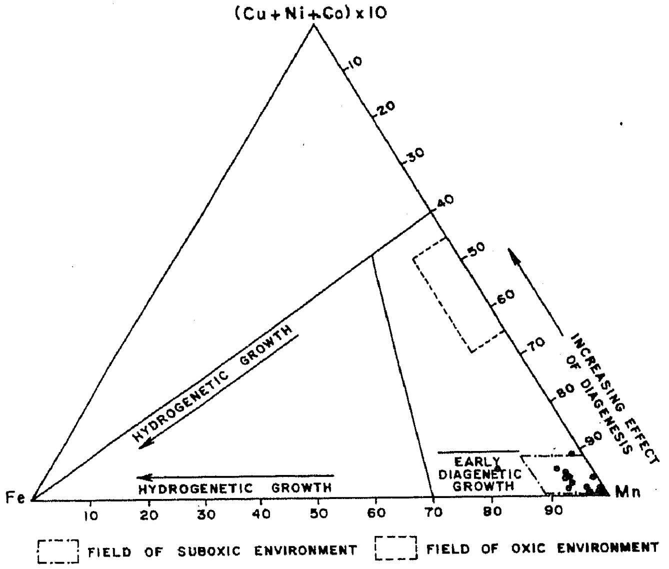

Figure 4. Plot of composition of micronodules from the area in Fe–Mn–(Cu + Ni + CO) × 10 triangular diagram. Most of the values fall in the field of suboxic environment.

below to oxic condition above is thus indicated by the dark brown pelagites in the present case. It is, therefore, inferred that micronodules of the study area have formed under suboxic conditions with diagenetic mobilization of Mn from the deeper levels and its precipitation at upper levels in the sediment column. This is in contrast to the oxic environment suggested for the formation of micronodules of CIB and for some occurrences in Bay of Bengal[12,2,11]. As in the present case, a few sub-bottom occurrences in the latter, however, have formed under suboxic condition too[11].

The sedimentation rate in the Arabian Abyssal Plain is 2–3 cm/10^3 yr (ref. 18). Higher rates of 4.6 to 9.8 cm/10^3 yr recorded from the northern Arabian Sea[19] are probably due to the influence of Indus discharge. The waning influence of Indus influx in the south might be another factor responsible for the abundance of micronodules in the southern part and their near-absence in the abyssal plain further west. Another critical feature is that on the western side the abyssal plain had received maximum turbiditic discharge from the Indus during the last glacial peak and on the eastern side forming the western slope of LR the sediments were contemporaneously laid at very slow rate. This must also have favoured nodule growth in the western slope of the LR but not far west in the abyssal plain.

Bioturbation by benthic organisms is cited as another reason for generating the oxidation processes or the means of Mn and Ni supply to the red clays of south Pacific[20]. In this process the burrowing activity is considered to provide furrows and pellets for Mn coating. Ni enrichment is attributed to precipitation by organic processes. Indications of intense bioturbation are seen in the present cores suggesting that elemental concentration by burrowing mechanism is a distinct possibility.

In conclusion, Mn-micronodules and coatings occur extensively in the slope region, west of the Lakshadweep Ridge at water depths of 2800–4400 m. They are usually found in the 5 to 20 cm thick dark brown pelagic clay host sediment which is interbedded with light coloured inhomogeneous sequence of hemipelagic clay/calcareous ooze. The sediment commonly lies 10–50 cm below the seabed. The abundance of the micronodules in the host sediment varies greatly between 2.6 and 24% by weight of the >0.05 mm fraction, but not exceeding 0.5% of the total sediment.

Birnessite is the dominant mineral in the Mn-micronodules. The nodules are rich in Mn (35.83%) and are in general Fe-depleted (1.82%) with Mn/Fe ratio averaging 31.10. They have highly variable content of common trace metals, viz. Cu, Ni, Co, Pb and Zn. Based on lithological characteristics, chemistry and mineralogy it is inferred that these nodules have been formed under suboxic condition with early diagenetic effect. The nodule growth is enhanced further by low rate of sedimentation and was possibly aided by bioturbation.

Seasonal variation in infestation characteristics of bagworm (Lepidoptera: Psychidae) in avenue plantation of *Acacia* and *Peltophorum* in the Chhattishgarh region

Arvind Agrawal, Atanu Kumar Pati and Deepak Karkun*

School of Life Sciences, Pt Ravishankar Shukla University, Raipur 492 010, India
*Department of Botany, Govt Arts and Science College, Durg 491 001, India

Seasonal infestation profile of bagworm, *Eumeta crameri* was constructed based on data recorded over a time scale of twelve consecutive months in the Chhattishgarh region. Two plantation sites consisting of 433 *Acacia nilotica* and 517 *Peltophorum pterocarpum* trees were chosen for the study. Plants were examined at monthly intervals and a visual score assignment system was employed to determine the degree of infestation. Cosinor technique was used to validate statistically significant annual rhythm in infestation characteristics. Results reveal that in both sites maximum outbreak of infestation occurred between November and January in the form of a single peak in each infestation parameter, notwithstanding evidence in favour of two additional generations during the study.

BAGWORMS are a group of highly specialized Lepidopterans belonging to the family Psychidae[1]. There are about 40 species available in the Indian territory[2]. Extreme development of sexual dimorphism in bagworm makes it a biological curiosity. The male bagworm moth is winged whereas the female lacks functional appendages. It spends the most part of its life inside a cylindrical/fusiform bag, which is open at both ends. The bag is constructed by the larva by using silken thread and other extraneous materials, such as leaves, spines, stems and twigs. Until pupation the larva keeps itself on the move from one branch to another in the host plant along with the bag, which is usually referred to as a mobile nest or case.

The bagworm has been documented as a serious defoliator of ornamental shrubs and trees throughout the Southeast and lower Midwest[3]. The potentiality of bagworm as a pest has been studied by several workers[4–7]. In India, until recently bagworms were not recognized as serious pests[2,4]. It has now been clearly established that many species of bagworms have already attained the status of a serious pest in Kerala.

Pteroma plagiophleps (Hampson) causes large scale defoliation of forest plantations of *Albizia falcateria* and *Delonix regia*[8,9]. However, very little is known about the bagworm species prevalent in this country. In this communication we document the prevalence of a population of bagworm species, *Eumeta crameri* and its infestation characteristics in selected avenue plantation sites in the Chhattishgarh region. In addition, seasonal infestation profile of *E. crameri* has been examined.

The *Acacia nilotica* plantations along the NH #6 passing through Bhilai (lat. 20°10′N; long. 81°20′E) and the avenue plantation of *Peltophorum pterocarpum* in the campus of Bhilai Steel Plant were chosen for the study. Plants in both sites with $n = 433$ and $n = 517$ respectively, were examined for bagworm infestation every month for a period of 12 months. A visual score assignment system was employed to determine the degree of infestation[10]. A plant was assigned a score of S_0, S_1, S_2, S_3 or S_4 representing respectively, no, low, medium, high and very high level of infestation. While the low level of infestation was characterized by the presence of at least one bag visible from the ground, the very high level was marked by sizable amount of defoliation[7]. The monthly intensity of infestation was computed and expressed as the ratio of number of plants in each score to the total number of plants, for example $I_1 = S_1/n$ (see Table 1).

Analysis of variance was used to validate statistically significant seasonal effect. In addition, an annual rhyth-

$I_1 = S_1/n$ (ratio of the frequency of plants which were assigned S_1 and total number of plants in the site); $I_2 = S_2/n$; $I_3 = S_3/n$; $I_4 = S_4/n$; $I_t = I_1 + I_2 + I_3 + I_4$.

mic variation for all the levels of infestation was characterized for both sites by the parameters of the best fitting cosine function approximating all data[11]. The rhythm parameters estimated by this least squares method include the mesor (M, rhythm adjusted annual mean), the amplitude (A, half of the difference between minimum and maximum of the best fitting cosine function) and the acrophase (ϕ, time of the annual peak obtained from this cosine function with local midnight of December 31 as ϕ reference). A rhythm is detected, with regard to the considered τ ($\tau \equiv 365.25$ days) when the amplitude differs from zero (non-null amplitude test) with $P \leq 0.05$. This single cosinor method[12] was employed for the original time series and also for the series obtained after fitting 3-item moving average. The latter was employed in order to smoothen the annual curve in the intensity of infestation[13]. Other conventional statistical techniques were also followed whenever required[14].

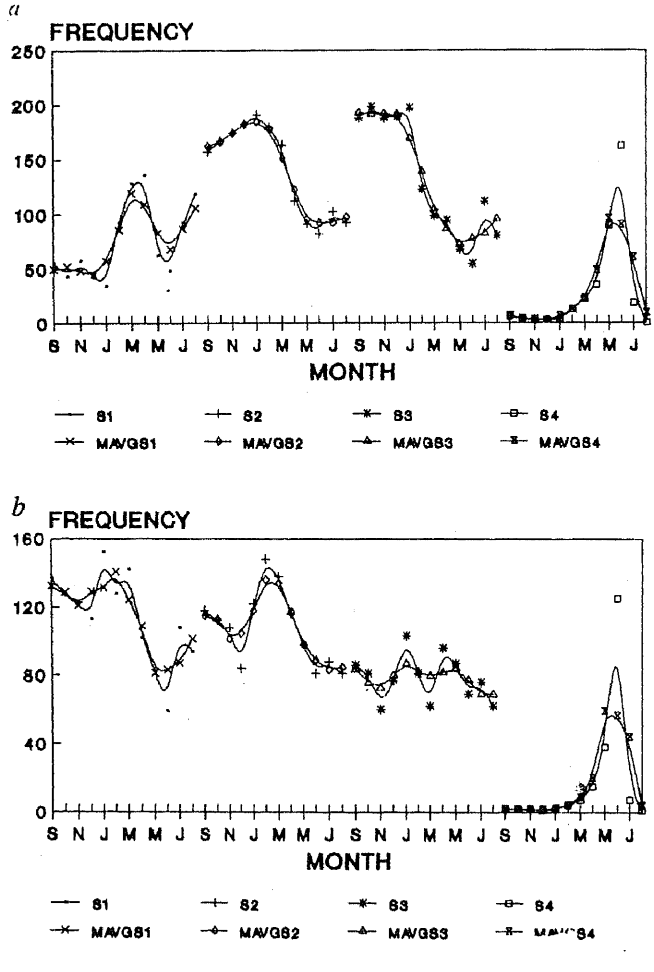

Figure 1. Seasonal variation in the levels of bagworm infestation in plantation sites of (*a*) *Acacia nilotica* and (*b*) *Peltophorum pterocarpum*. S_1, S_2, S_3 and S_4 denote original data indicating low, medium, high and very high level of infestation, respectively. $MAVGS_1$, $MAVGS_2$, $MAVGS_3$ and $MAVGS_4$ denote 3-item moving average fitted data of the time series, S_1, S_2, S_3 and S_4 respectively.

The seasonal variation in intensity of infestation was examined over a period of twelve months. Both original and 3-item moving average fitted time series were plotted as a function of the time of the year (Figures 1 *a,b*). The monthly intensity of infestation was gauged by computing the ratio of number of plants in each score to the total number of plants. The sum of all the ratios in each month was computed and expressed as the total infestation intensity (Table 1). A statistically significant month effect was validated by ANOVA only for I_4 level of infestation intensity (Table 2). The masking of month effect for other intensity of infestation levels could be because of the disparity in infestations between *P. pterocarpum* and *A. nilotica* leading to neutralization of such effect. However, a highly statistically significant species effect was documented for all the levels of infestation intensity excluding I_1 (Table 2). The results reveal that *A. nilotica* was more heavily infested with bagworms than *P. pterocarpum*. Table 3 shows the results of cosinor analysis employed on 3-item moving average fitted time series. A statistically significant annual rhythm was validated for almost all the infestation parameter, excepting S_3 in *P. pterocarpum*. The annual peaks for $S_1 + S_2 + S_3$ infestation intensity occurred on November 27 and December 27 in *Acacia* and *Peltophorum* plantations respectively (Table 3). The peak map is shown in Figure 2, which indicates that 95% confidence limits in peaks for most of the infestation parameters, irrespective of host plants, overlap with each other.

This is the first study that concerns bagworm infestation in the Chhattishgarh region. As such there are limited centers in India where work of comparable nature is being carried out. Prominent among these is the Kerala Forest Research Institute at Peechi. Until 1981 the bagworm, *Pteroma plagiophleps* was known as a minor pest of *Tamarindus indica* in India, when Nair *et al.*[8] demonstrated that *P. plagiophleps* has already assumed

Table 2. Summary of the results of ANOVA* employed to analyse seasonal infestation intensity

Infestation characteristics**	Main effect	
	Species (df 1.11)	Month (df 11.11)
I_1	0.067^{NS}	1.6^{NS}
I_2	26.333^{c}	2.667^{NS}
I_3	15.444^{b}	0.889^{NS}
I_4	7.0^{a}	16.0^{c}
I_t	25.869^{c}	2.087^{NS}

*ANOVA based on data shown in Table 1. Since only one score was obtained for each level of infestation in each month, species × months interaction mean square has been used as the error mean square.
**Computed as the ratio of number of plants in a given level of infestation and total number of plants.
NS = Not significant; $^{a}P \leq 0.05$; $^{b}P \leq 0.01$; $^{c}P \leq 0.001$.

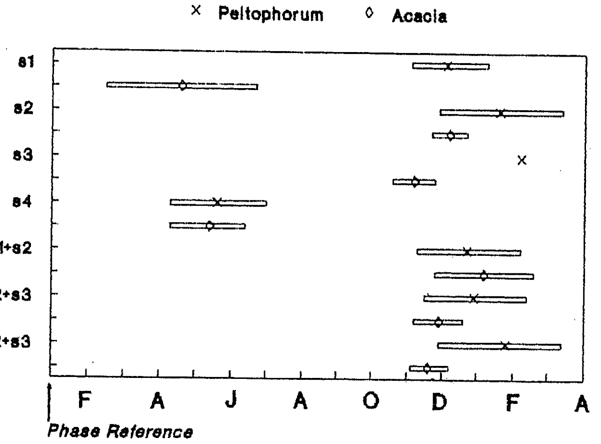

Figure 2. Peak map. Each point represents the peak in the levels of infestation over an annual time scale with December 31 as the phase reference. Both ends of the horizontal bar define the range of the 95% confidence limit of the peak infestation. The absence of bar indicates nondetection of statistically significant annual rhythm.

the status of a serious pest of *A. falcataria*, a fast growing tree species introduced from Mohccas[15]. This suggests that the bagworms are notoriously polyphagus and have the capability to switch over to a new host. It can cause heavy defoliation in various plantation sites. For *P. plagiophleps*, Nair *et al.*[8] reported that it is likely to become a limiting factor for successful raising of *A. falcataria* plantations in Kerala. In addition, *Eumeta crameri*, *Metisa palma* and *Brachycyttarus subteralbatus*, each of them alone or together, have been documented as pests of important tree species, such as *Delonix regia*, *Tectona grandis*, *Manatha albipes*, *Terminalia catappa*, *T. indica* and *Casuarina equisetifolia*.

The studies on the dynamics of seasonal infestation caused by *E. crameri* of avenue plantations of *P. pterocarpum* and *A. nilotica* reveal that in both cases maximum outbreak is restricted to the winter months. The maximum infestation of *Peltophorum* is in December with a spread between beginning of November and mid February. However, in *Acacia* the highest infestation was noticed in November with a spread between beginning of November and the third quarter of December. Although these observations suggest that the bagworms reproduce only once in a year, the actual observations on life cycle of *E. crameri* indicate that it breeds at least 3 times in a year notably in July, October and January. It is not known why 3-item moving average fitted time series did not reveal all the generations in the form of peaks in infestation intensity. Similar kind of masking has also been reported for infestation of *P. plagiophleps* in *A. falcataria* plantations[7]. It could be reasonable to imagine that there might be some unknown natural limiting factors behind this phenomenon of masking. The pest management could become effective only when the principles which govern outbreaks of infestation are known.

This study assumes a lot of significance from regional context specially because it documents infestation profile in *A. nilotica* plantations. This plant is a common sight in the rice fields of the Chhattishgarh and being a leguminous plant it fixes atmospheric nitrogen and its compound leaves with small pinna do not obstruct the sun rays. This plant also has great economic value.

It is being used as fuel, charcoal, timber for agricultural implements and also carpentry[16]. The farmers of this region use its timber in making cart wheel and plough. In addition, it is used to make pulp in paper and rayon industries and its bark in fermentation technology for manufacturing country liquor[17]. It has also been shown to be of great value in the management of rain water in alkali soils[18].

In conclusion, the bagworm appears to be of great economic significance and therefore, a nation wide operation is desirable with a view to documenting the species and their hosts from all the corners of the country.

Analysis of gene expression during embryonic development in mulberry silkworm *Bombyx mori*

Amit Singh and Karumathil P. Gopinathan

Microbiology and Cell Biology Department, Indian Institute of Science, Bangalore 560 012, India

We have developed a method for dechorionation and devitellinization of the silkworm eggs without damage, to facilitate the analysis of gene expression during embryonic development of *Bombyx mori*. Making use of antibodies available from heterologous systems, the spatio-temporal expression patterns of *peroxidase* and *proliferating cell nuclear antigen* have been directly visualized in whole mount embryos at various stages of development without the need for generating transformed lines carrying specific reporter constructs. The *B. mori* system, previously unamenable for such studies, could thus serve as an attractive model for molecular analysis of insect development.

THE attention lavished on *Drosophila melanogaster* as the insect species *par excellence* for the genetic and molecular analysis of development, has eclipsed the earlier investigations on most other insects for a multitude of challenging biological phenomena. The mulberry silkworm, *Bombyx mori* has a genetic legacy comparable to that of *Drosophila*, but most of the efforts on the silkworm were channelled towards the improvement of the race through breeding, due to its economic importance[1,2].

The extended period of embryonic development of *B. mori* (10 days as compared to 24 h in *Drosophila* and 100 h in *Manduca sexta*, another widely studied Lepidopteran insect) provides an advantage to discretely analyse without overlap, the events leading to pattern formation. The early investigations on *B. mori* were confined to the problems of diapause[3] and storage of embryos or towards the elucidation of morphological landmarks by electron microscopy[3–5] and fluorescent vital dyes[6]. Recently the fate mapping of *B. mori* embryo has been carried out following laser irradiation[7]. The investigations on gene expression during early embryonic development of silkworm have lagged behind because the dechorionation and devitellinization of embryos proved to be major hurdles. Besides, the embryonic development could not be examined due to the nonavailability of cell type-specific molecular markers as well as the lack of transgenic methodologies. In such situations the immunocytochemical approaches provide an alternative. Antibodies against gene products can be exploited as tissue- and cell-specific markers to analyse phenotypes in mutant embryos[8–15]. Recent studies[8–17] have implicated the evolutionary conservation, based on sequence similarity of developmentally important genes, in a range of distantly related species. As a consequence, immunologic probes from heterologous sources could prove to be useful in detailed tracking of individual gene products during development. There is a distinct need, however, to adopt the existing methodologies to the *B. mori* system, where a major hurdle exists due to the presence of a thick chorion layer encasing the egg which affects the permeability of the embryo to external probes.

Here, we have improvised a protocol for the dechorionation and devitellinization of *B. mori* embryos to facilitate the analysis of spatio-temporal expression of genes during development. We have also exploited the heterologous antibodies against *Drosophila* gene products to examine the pattern of gene expression during embryonic development of silkworm and demonstrate that the system is now amenable for such analysis.

B. mori egg is a flattened sphere, 1.2 mm long, 0.95 mm wide and 0.63 mm thick and is encased in an envelope of chorion (Figure 1 *a*). The antero-posterior and dorso-ventral axes of the egg are clearly discernible from the flattened shape of the anterior side. The surface of the chorion shows hexagonal spots with no subdivisions and an anteriorly situated micropyle (Figure 1 *b*) which permits sperm entry.

B. mori follows a characteristic embryonic development pattern which essentially resembles the 'long germband' insects but with distinctive characters of its own (Figure 2). In brief, the major landmarks during embryonic development are syncitial blastoderm (12 h after egg laying), germband formation (20 h), gastrulation (25 h), generation of segmental body plan (35 h) and blastokinesis which initiates from the 4th day and lasts till 5th day. During blastokinesis, the developing larva makes a complete turnaround from its initial position and along with it the developing legs and the pseudopods get located into the interior. This revolution of embryo is an interesting feature of *B. mori* development. By the 7th day the complete functional larva is formed which hatches out only on the 10th day. Studies on the developmental expression of the genes during embryogenesis in *B. mori* could not be done previously due to problems of dechorionation and devitellinization of the eggs. The thick chorion can neither be removed mechanically during earlier stages of embryonic development as in *Drosophila*[18] nor its permeability be increased to stain the embryo without removal of chorion as practised in zebra fish[19]. Moreover, the thickness of the *B. mori* embryos reduces microscopic resolution of the staining patterns.

Eggs (embryos) were washed in distilled water to remove the glue covering them and suspended in PBT (PBS + 0.1% TritonX-100) containing 0.1% proteinase K for 15 min. They were dechorionated in 5% hypochlorite bleach for 5 min followed by the addition of an equal volume of heptane. On dechorionation the embryos pop into the organic heptane layer preventing any damage. We tried different concentrations of the hypochlorite bleach and found that a higher concentration (5%) was necessary to dechorionate *B. mori* eggs. Pretreatment of eggs with proteinase K further improved the effectiveness of the bleach. The presence of heptane allowed the immediate relocation of the dechorionated

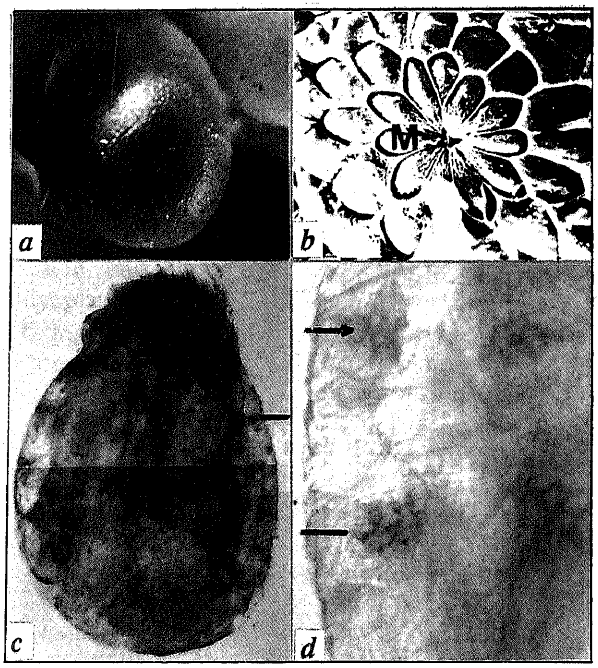

Figure 1. Whole mount embryonic staining using anti-HRP antibody. ***a***, *Bombyx mori* egg (× 15), seen under stereo microscope (Olympus). ***b***, Scanning electron micrograph (JEOL) of the egg shell surface (× 1000).

Eggs were collected at 30 min intervals and maintained at 25°C. The time of embryonic development is referred to as 'hours after egg laying' (AEL) and hatching occurs 10 days after oviposition. For staining, the dechorionated embryos were fixed in equal volumes of heptane and the fixative (4% paraformaldehyde in PBT, 1 mM $MgSO_4$, 2 mM EGTA) for 40 min with continuous shaking. These embryos were flushed thrice with methanol to remove the fixative and stored in methanol at – 20°C. Prior to antibody staining, the embryos were rehydrated in several changes of PBT followed by three washes of PBTA (PBT + 1% bovine serum albumin) for 2 h and incubated overnight at 4°C in primary antibody. After primary antibody reactions, the samples were washed in three changes of PBTA for 10 min each at room temperature, treated with the secondary antibody for 2 h at 4°C and the expression was monitored.

For detecting *peroxidase* expression (as marker for the neuronal development), the dechorionated embryos were treated with anti-horse radish peroxidase (HRP) antibody, followed by treatment with the secondary, goat anti-rabbit IgG coupled to HRP as the detection system. HRP activity was detected by staining with 0.5 mg/ml of diaminobenzidine and 0.01% H_2O_2. The stained specimen were observed under DIC optics on an Olympus microscope. ***c***, Whole mount embryo (6th day of embryogenesis). ***d***, Magnified view of a bundle of sensory bristle on embryonic ectoderm (× 100). Controls, in which the primary antibody was left out prior to the reaction with the anti-antibody, did not show colour development. For comparison of the embryonic development stage, see Figure 2.

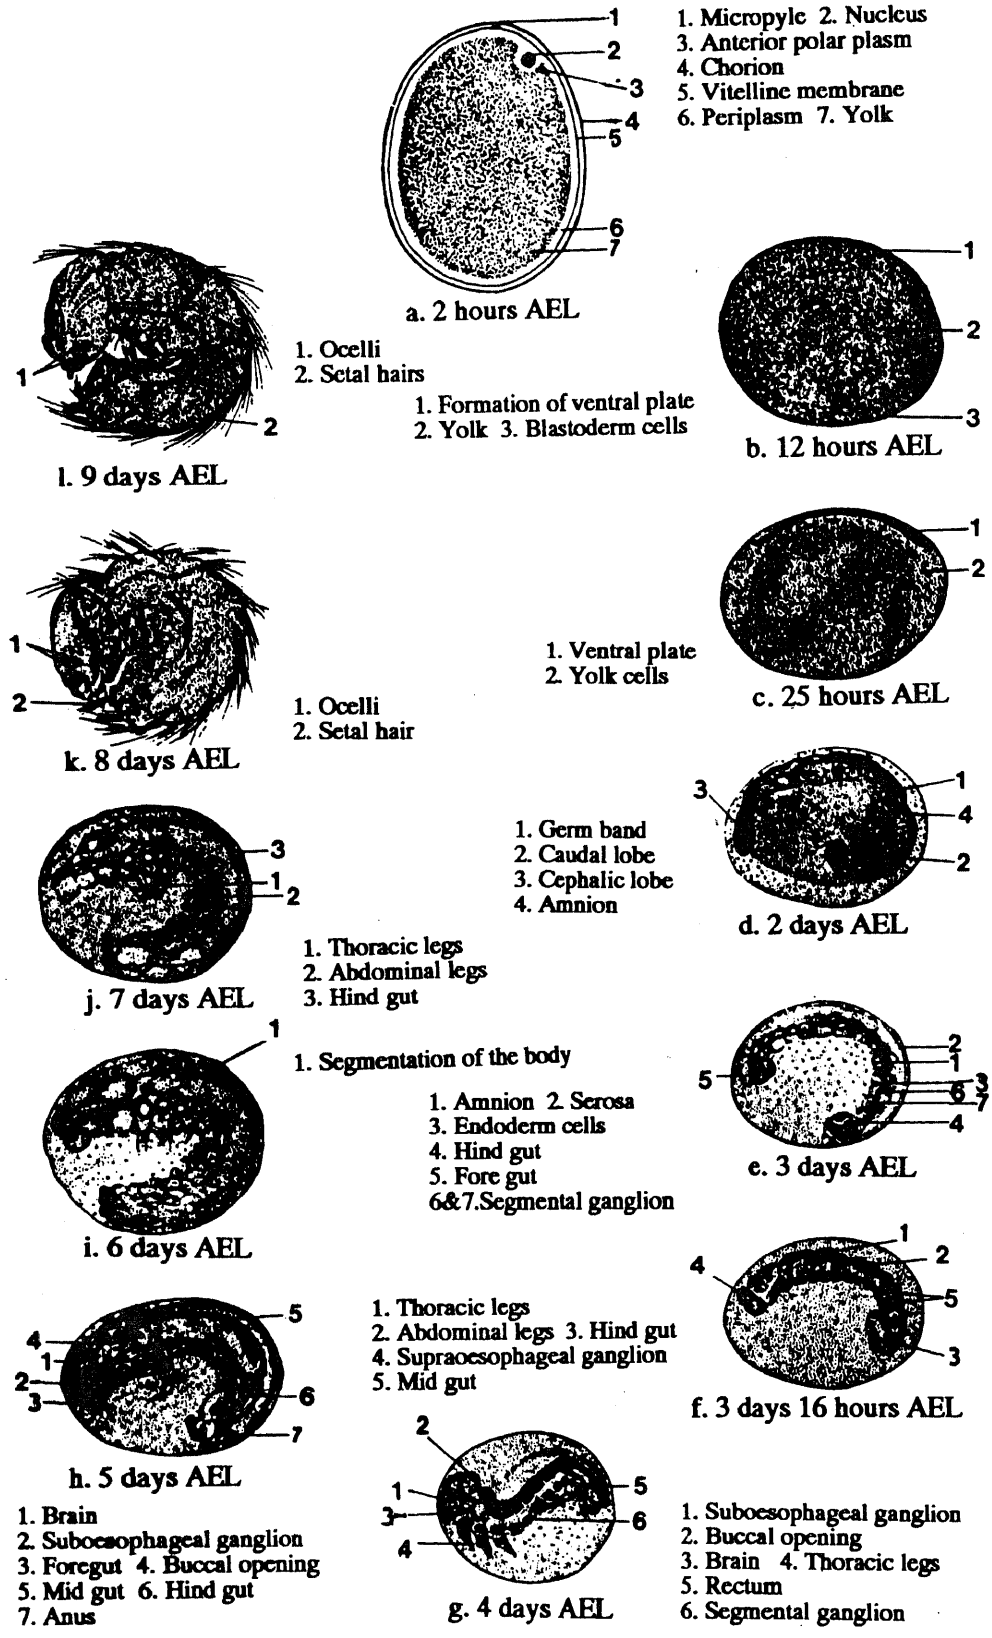

Figure 2. Schematic presentation of the embryonic development of silkworm *B. mori*. Various landmarks of the embryonic development along the temporal scale are depicted. ***a***, Structure of silkworm egg. ***b***, Cleavage and blastoderm formation. ***c–f***, Germband formation. ***g–h***, Blastokinesis. ***i–l***, Completion of embryonic development.

embryos to the organic layer. The relatively brief exposure of embryos to higher concentration of bleach along with an interface of heptane has allowed us to achieve chemical dechorionation successfully with higher yields and less morphological damages.

Such dechorionated embryos were devitellinized in heptane–methanol interphase[18] and examined for the expression of different genetic markers by making use of heterologous antibodies. The expression patterns of *peroxidase* and *proliferating cell nuclear antigen* (*pcna*) were examined using rabbit polyclonal antibodies raised against horse radish peroxidase (HRP) or *Drosophila* PCNA respectively. The appearance of peroxidase activity has been taken as an expression marker for nervous tissue development[20]. The expression of *peroxidase* was detected in basal cells of the sensory hair on the ectoderm of the silkworm embryo at the 6th day of development (Figure 1 *c,d*; arrowhead). Suitable controls were included while conducting the antibody staining reaction (where the samples were treated only with the secondary antibody with no prior treatment of primary antibodies) to rule out any possible artefacts. In fact, little information has been documented in the past on neuronal development during silkworm embryogenesis. The present approach thus serves as a convenient means for such analyses, if various nervous system specific markers are used as probes along the temporal scale.

The approach for the detection of gene expression was extended further to study the expression of *pcna*. PCNA is involved in several vital processes of cell division and DNA replication, and its presence could be expected in all dividing cells during development. Using antibodies, *pcna* expression was detected initially at 10 h of development at the cellular blastoderm stage confined to the periphery of the embryo (Figure 3 *a*). At 20 h of development *pcna* expression further evolved in the developing germband on the ventral side of the embryos, marking all the developing segments (Figure 3 *b*). During gastrulation movements at 25 h after egg laying, it was expressed in all the developing segments of the silkworm embryos which further refined at the end of 35 h expressing in all the seven head-, three thoracic- and eleven abdominal segments of the larval body plan (Figure 3 *c,d*).

Using the methodologies established here, the *B. mori* system with its excellent genetic backup can be exploited to serve as an alternative model system to study gene expression. The extensively studied insect *Drosophila*

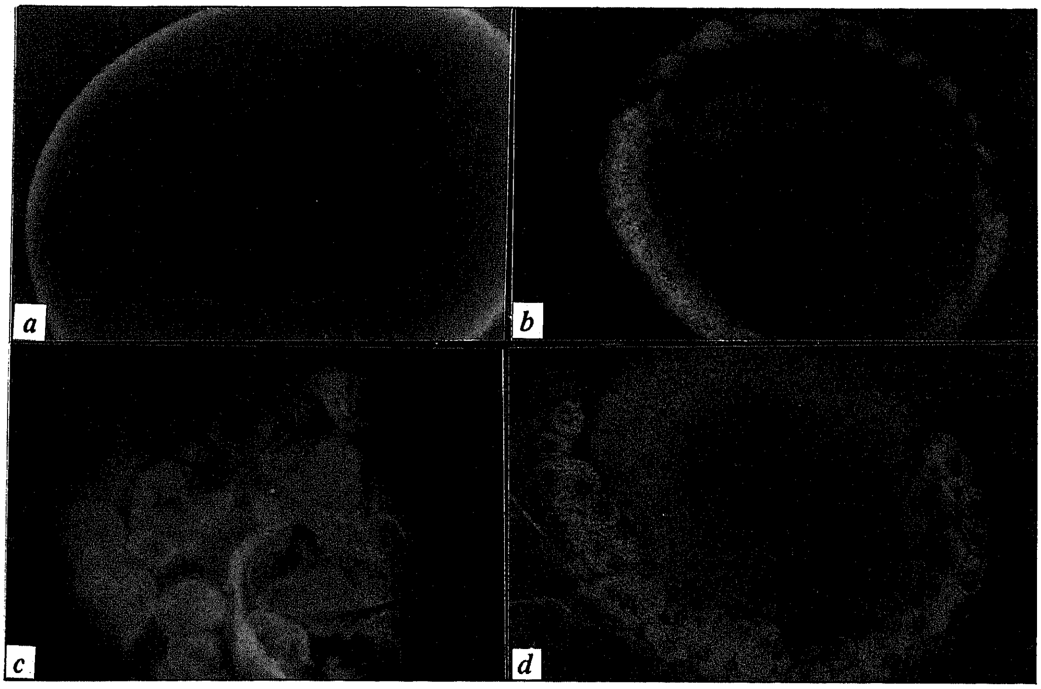

Figure 3. Embryonic expression of *proliferating cell nuclear antigen*. The dechorionated embryos were treated with rabbit polyclonal antibody to *Drosophila* PCNA and the reactions were visualized using goat anti-rabbit antibody conjugated to fluorescein isothiocyanate. The specimen was examined under an Argon Laser Confocal Microscope (Biorad MRC 1000). ***a***, Expression at the syncitial blastoderm stage, optical cross section at 10 h after egg laying (AEL) (× 10). ***b***, Developing germband with formation of the segments as shown by arrow head at 20 h AEL. ***c***, Cellular movement of gastrulation at 25 h AEL. ***d***, Embryo at 35 h AEL with well-developed germband. Note the expression is uniformly distributed in the entire germband with several pockets of rapidly dividing cells. Controls in which the primary antibody treatment was omitted, were always included, and they did not show staining. For comparison of the embryonic development stages, see Figure 2.

belongs to the phylogenetically evolved order Diptera and not necessarily represent all insect groups. The embryogenesis in *Drosophila* is rather unusual compared to other Arthropods[21–24]. Comparison with the more 'typical' insects may provide further insights as to which aspects of embryogenesis are widespread and which are phylogenetically restricted. Lepidopterans being separated by more than 200 million years from Diptera, should provide an important window on evolutionary innovations relative to *Drosophila*. This will offer two complementary approaches deducing both ontogenic and phylogenetic mechanisms[23].

Annual Review of Medicine: Selected Topics in Clinical Sciences. Coggins, Hancock and Levitt, eds. Annual Reviews Inc., 4139, El Caminoway, P.O. Box 10139, Palo Alto, California 94303–0139, USA. Vol. 47, 1996, 596 pp. Price: US $ 52. Elsewhere $ 57.

The Annual Review of Medicine is different from others such as the *Annual Review of Biochemistry* in that the subject matter is broad, covering every aspect of laboratory and clinical medicine. At least in this sense the *Annual Review of Clinical Medicine* is a misfit in the stable of superbly focused publications produced yearly by Annual Reviews Inc. This is not to detract from the quality of effort that has gone into assembling the contents. Indeed, with 44 articles crowding 566 pages this may be the most densely packed of the Annual Reviews, reflecting an attempt to be eclectic as well as comprehensive in the limited space available.

Given burgeoning research in human molecular biology, it is not surprising that molecular medicine is well represented in the contents. Many of these articles offer tantalizing glimpses into the future of medicine and it may be many years before these ideas are translated into practical applications. However, innovations in medicine are not always byproducts of molecular biology. Some important advances relate to better treatments, as well as better use of existing treatments. Lastly, it should be kept in mind that modern medicine is extremely expensive and the 'good old' remedies still have a place, provided their role is reassessed continuously, in view of the rapid flow of new information. The articles in this volume pay heed to all these themes and a few examples will serve to illustrate this.

While it is well recognized that the 'placebo effect' is a real and measurable response of patients to inert principles no effort has been made to systematically harness it for the benefit of patients. Indeed, physicians are trained during the evaluation of new medicines to devise ingenious means, such as masking, to discount the placebo component of a patient's response to medicines. The article on the Placebo Effect by Herbert Benson and Richard Friedman makes a case for 'harnessing' the power of the placebo to benefit patients in the practice of clinical medicine. Since the response to an active medicine will also have a placebo component it is difficult to understand what the authors mean when they exhort the reader to 'incorporate it into standard treatment'. However, the authors do make the valid point that the 'placebo' component of response can be maximized through closer and increased doctor–patient interactions. No doubt, proponents of alternative systems of medicine will take issue with the authors' suggestion that most alternative medicines are placebos. Some may also question the need to replace the elegant and well-understood term 'placebo effect' with the clumsy neologism 'remembered wellness'. Medicine is full of meaningless jargon without our having to add more.

Gene therapy finds place in this volume in the form of a review by Cynthia Dunbar of the NIH, USA, of the use of hematopoietic cells as vehicles for introduction of genes. Hematopoietic cells are conveniently accessible and the progeny derived from the original stem cell also carry the introduced gene, making available a clonal population of cells producing the gene product. This technique is advanced enough to have reached early clinical trials. The results from these studies and the development of new vectors for the transfer of genes will place gene therapy on a firm footing. Also falling within the domain of molecular medicine are excellent reviews on 'trinucleotide instability', X-linked severe combined immuno-deficiency', 'the p53 gene' and 'apolipoprotein E alleles in Alzheimer's disease'.

The article on the mechanism of action of lithium in the treatment of manic depression is a catalogue of results from experiments that aim to prove that the action of lithium in modulating brain function is a result of depletion of inositol. While the findings are provocative they are far from being conclusive and most clinicians would probably not find this contribution of any practical interest. There are several rather confusing findings that the authors gloss over. One glaring finding is that while lithium decreases brain inositol, inositol itself has antidepressant effects. The hand waving resorted to at the end of this chapter does not resolve this paradox in a satisfactory manner.

There are two articles that diabetologists may find interesting. One covers 'beta-cell function' and the other discusses the 'genetics of NIDDM'. Although insulin resistance is the current fashionable topic among diabetologists, the former article reminds us of the importance of beta-cell dysfunction in NIDDM characterized by an abnormal insulin response to a glucose load. No doubt, the controversy regarding which came first, insulin resistance or beta-cell dysfunction, will remain with us. The latter article on the 'genetics of NIDDM' is probably fascinating to researchers who have many potential targets to fish for but dissatisfying to clinicians who are not presented with the possibility of an integrated molecular approach to NIDDM. Research in this area is still in 'the more we understand the less we know realm'. In a similar vein articles on 'myocardial preconditioning for cardioprotection' and the 'role of antiinflammatory drugs in Alzheimer's diseases' offer a fascinating glimpse into what may become possible in the near future.

A few chapters seem a little out of place in this collection such as the one on the 'implantable cardioverter defibrillator', 'laparoscopic cholecystectomy', 'laxative abuse', 'fatal asthma' and 'Bartonellosis'. These contributions may be better suited for a textbook of medicine rather than the Annual Reviews. The editors should also possibly consider issuing a separate volume with the title 'Annual Reviews of Molecular Medicine' given the accelerating growth of new information in that area.

A set of up-to-date references accompany each contribution and makes this volume useful for those seeking the original contributions. The compact size of the book makes it suitable for bedside reading. A large number of line drawings and schemes have been included that makes the subject matter easily accessible. However, the labels associated with the figures are of poor quality. The small blurb that appears at the end of each chapter advertising ordering information for reprints is a little irritating and could probably have been made to appear once at the end of the book.

The very reason that this compilation is unique may be why this book may lack punch. Within the covers of this book are reviews spanning such a variety of topics that only the generalist with plenty of time will be able to read more than a minor fraction of the articles. One gets the feeling that unlike subjects like biochemistry, the topics that fall under the rubric of clinical medicine are not amenable to coverage in one volume without a persistent undercurrent of tension resulting from the need to provide both breadth and depth of coverage. Nevertheless, for the rare (at least in India) breed of laboratory clinicians there is enough in this volume to make it a delightful companion.

SWAMINATHAN SUBRAHMANIAM

Dr Reddy's Research Foundation,
Bollaram Road, Miyapur,
Hyderabad 500 050, India

Mineral Resources of Karnataka. B. P. Radhakrishna, Geological Society of India, P. B. No. 1922, Bangalore 560 019. 471 pp. Price: Rs 200, $ 25.

Mineral Resources of Karnataka by B. P. Radhakrishna (BPR, as he is fondly referred to within the earthscience fraternity) represents the handiwork of the right-man-on-the-right-job. None perhaps qualifies better for this specific job.

The 471-page volume, written with a view to 'disseminating available know ledge and educating the public on the mineral resource potential of the State', is divided into two major sections. The first part (though not explicitly labelled as such) comprising four chapters deals with history of two different kinds: the developmental *history of the mineral industry* in Karnataka since ancient times, set against the backdrop of the Indian mineral–industrial scenario; and the *tectonic-metallogenic evolutionary history* of the region in the context of global metallogenesis in space–time coordinates. BPR is eminently knowledgeable about and authoritatively competent in handling both kinds. The second part comprises 'commodity reports' on various types of mineral resources of the State.

The entire text, especially the preface and the introductory section, reflects the author's economic philosophy that has a Gandhian aura about it: self-sufficiency, self-reliance, small-scale labour-intensive mineral enterprises in rural areas; emphasis on development of low unit-value commodities (like sand or building stones) that are useful to virtually everyone; repeated plea for indigenous technology and for export of 'processed' goods rather than 'raw' ore materials, etc. A conviction, that the small-is-beautiful concept is *appropriate* and *applicable* in our context, pervades throughout. One may disagree and consider all this too simplistic in an era when giant multinational mining corporations rule the roost the world over, but the conviction unmistakably stems from his personal, and successful, experience, with the Hutti–Tintini–Chitradurga tie-up in which he had been a major influence.

A few statements are slightly disconcerting though. Like 'Non-ferrous metals . . . although not abundant, can still meet the limited *requirements of the State*' or '. . . mineral resources have not been exploited to the *best advantage of the State and its people*' (p. 2), or 'Mineral development and administration are *best left to the individual States* (p.v. – all italics mine). Surely no 'myopia' needs be casually diagnosed, no sub-nationalism needs be read here – not from BPR, a national figure in his prefession. But such emphasis may send wrong signals that the interest of the country and that of its constituent states are not compatible.

Since the targetted readership is 'the public' (presumably including legislators, planners, administrators and other decision-makers) as also the earth scientists, the balancing job has proved to be rather daunting. The reviewer, for one, was excited at the prospect of sharing the rich experience and wisdom of BPR but had to be content with summarized treatments of geology of the ore deposits – a treatment dictated by the choice of 'the public' as the primary target for whom simplification is often inescapable. Nevertheless the contention, that 'ocean floor . . . volcanic rocks spread out and become continents through successive collision and separation' (p. 30), is *unacceptably oversimplified.* Similarly, placing the stratiform complexes (with Cr, Ni, Ti, V mineralization) under 'Volcanogenic mineralization' (p. 44), or classifying arenite-hosted copper sulfide deposits as 'detrital or placer deposits' (p.161) would have few takers!

Some discrepancies in the hierarchy of sub-heading should better have been avoided; for instance, under the heading 'ARCHEAN' (p. 35–40), subheads like 'Gold in banded iron formation', 'Gold in Greywacke', 'Au–U bearing quartz pebble conglomerate', etc. enjoy the same hierarchical status – anomalously, to my mind – as those on the 'Eastern Schist Belt' and the 'Western Schist Belt' both of which deserve higher-order status in the scheme of organization.

The section on 'Commodity Reports' (p. 47–471), arguably the *raison d'etre* for the book, bears the unmistakable stamp of BPR's intimate knowledge of virtually every single deposit/occurrence in Karnataka. Geology of important deposits is discussed – briefly, simply and lucidly for the general readers, but alas somewhat inadequately for professional geologists. The section could perhaps have done with some standard formatization (like that in the Mineral Commodity Summaries published by the US Bureau of Mines). Was the inclusion of items like 'andalusite' warranted really?

The production is trim and attractive, virtually free from printing errors. Reproduction of geological maps and cross-sections is of high quality as also are the beautiful colour photographs of polished ornamental stones.

Overall, the book is a valuable addition to our rather meagre repository of texts on geology and economics of mineral deposits of the country or of a State. If the review sounds captious at any point, it is because expectation from BPR is always high. How much I wish the text were to discuss the geology of ore deposits in Karnataka in sufficient detail and present the compilation of mineral statistics and mine directory as an appendix!

ASOKE MOOKHERJEE

Jadavpur University,
Calcutta 700 032, India

Fundamentals of Aquacultural Engineering. Thomas B. Lawson. Chapman & Hall, USA. ISBN 0-412-06511-8. 355 pp. $ 45.

With the global fish production fast approaching the maximum sustainable yield, the role of aquaculture as an important contributor to high quality food production has become more apparent in recent years. The concept of aquaculture has shifted from traditional methods to more of a commercial operation, with attempts to maximize the production from a given waterbody. Commercial aquaculture is not simply a biological operation, but a complex, multidisciplinary activity involving the expertise of biologists, engineers, economists and others. In this context, the *Fundamentals of Aquacultural Engineering,* stands out prominently among the volumes of books on aquaculture. The author, basically a freshwater aquaculture engineer has brought out the fundamentals of aquaculture engineering principles in simple technical terms in the 12 chapters of this book.

Aquaculture production, to a great extent, is influenced by the physical, chemical and biological characteristics of the environment and their interactions. The aquaculturist should have know ledge of water quality and the environmental requirements of the cultured organism for the venture to be successful. Chapter 2 provides practical information on water quality standards for aquaculture. The illustrations and examples are mostly drawn from freshwater aquaculture and may not be directly applicable to mariculture though the basic processes are common to both the systems. Chapters 3 and 4 briefly highlight the factors that should be considered while selecting a suitable site and water source for freshwater aquaculture.

Among the various culture systems developed for open waterbodies, the technology for cage culture has evolved essentially from engineering techniques. The bulk of the section on aquaculture in open systems presents a fairly good overview of this subject. Inadequate knowledge of water requirements and poor selection of pumps can result in significantly increased operating and maintenance costs and result in crop failure. In the three chapters, fluid mechanics, pumps and flow estimation and measurement, the author presents the basic engineering principles of fluid dynamics, functioning of different types of pumps and methods for sensing and maintaining water levels in ponds with illustrations and practical examples. This information will be very useful to the aquaculture engineer as well as the entrepreneur.

Success of aquaculture in ponds, raceways and tanks to a great extent depends on the engineering design of the system. Chapter 9 provides the basic structural designs and tips for water and waste management in these three advanced culture systems. This information which rarely finds place in many of the aquaculture books is quite useful for the aquaculturists. Good quality water is likely to become a limiting factor for aquaculture, and therefore, water reuse systems have been gaining more attention, recently. Recirculation systems offer advantage of water saving, reduced risk of external contamination and better environmental control. The author deserves appreciation for a detailed presentation concerning the principles and various methods of water treatment in the chapter on Recirculating Aquaculture Systems. Equally commendable is the chapter on oxygen and aeration which discusses the fundamental principles of aeration, aerator devices and application practices in aquaculture. In fact, the author earmarked a major portion of the book to this important aspect as many farmers are ignorant of the benefits of aeration on production. The last chapter on sterilization and disinfection is very relevant as disease transmission is on the increase with the intensification of aquaculture. There are a number of readily accepted methods of treatment. The merits and demerits of different treatments are broadly discussed.

This book is undoubtedly an useful practical guide not only to the aquaculture engineering students, but also the fishery biologists, the practising engineers and the aquaculturists. Most of the examples are from temperate freshwater aquaculture, though aqua- culture is more of a tropical occupation. The book deals basically with freshwater aquaculture engineering, but it is equally useful to the mariculturists. The exhaustive bibliography will be beneficial to the students in obtaining additional information on specific topics of interest in their respective fields.

Pramatha Nath Bose (1855–1934)

B. P. Radhakrishna

Three years ago, I was pleasantly surprised to receive a letter from Dr Chandan Roychaudhuri, Secretary of the Asiatic Society, conveying the decision of the Council of the Society to award the Pramatha Nath Bose Memorial Medal to me for the year 1990. Excepting a vague recollection that P. N. Bose was connected with the discovery of the rich iron ore deposits of Gurumahisani, I knew little about him for his contributions to knowledge. My curiosity to know more about this first Indian to join the Geological Survey of India was aroused and since then I have been able to collect some information about the life and achievements of this remarkable personality. I would like to share this knowledge with the readers of the journal so that they too can come to recognize the merits of this great son of India and his contributions to the advancement of earth science education in this country.

Early life

Pramatha Nath Bose was born on 12th May, 1855, at Gaipur, a village then in the district of Nadia, but now in 24-Paraganas of Bengal, the second child of Taraprasanna Bose and Sashimukhi. Recalling his boyhood days at Gaipur, Pramatha Nath has written 'we had the five best physicians – sunshine, air, water, exercise and diet'.

Pramatha Nath had his early schooling in the *Bangabidyalaya*, the village school, till he was nine years old and then moved to Krishnagar where he came under the influence of the famous Bramho reformer Keshab Chander Sen. He conceived the idea of going to England for higher studies and appeared for the competitive examination to secure the coveted Gilchrist Scholarship instituted in 1887–88 for talented Indian students. He stood first in the examination and secured the scholarship which was tenable for five years.

Stay in England

Pramatha Nath sailed for England in September 1874 and stayed in London for nearly six years. The subjects which he chose for study included chemistry, botany, geology, zoology, physical geography and logic. After his graduation from the London University in 1877, securing the third position in geology, he joined the Royal School of Mines for a short period. He took part in political meetings and started criticizing the acts of government. Officials of the India Office did not like his activities and wanted to pack him off to India. It is said that the British Government of the day went out of the way to offer him a job in the Geological Survey of India. Bose has recorded 'This was the first case in which the Secretary of State exercised his discretion in favour of an Indian in regard to the appointment in his patronage'.

Marriage with Kamala

Pramatha Nath returned to India in July 1880, a true nationalist and on July 24, 1882, married Kamala, daughter of Ramesh Chander Dutt, a noted Sanskrit scholar. It is interesting to recall that the marriage was attended by many literary celebrities of the day including Bankim Chandra, the author of *Vande Mataram* and the budding poet Rabindranath Tagore. Rabindranath has recalled in his autobiography (*Jeevan Smruti*) that when Ramesh Chander Dutt came to garland Bankim Chandra, the great novelist took the garland from Dutt's hand and placed it round the neck of the young poet Rabindranath much to the astonishment of those present. Rabindranath later became a pupil of Bose.

Service in the Geological Survey of India

Pramatha Nath joined the Geological Survey of India on 30th July, 1880, i.e. earlier than La Touche (1881) and Middlemiss (1883). He was the first Indian to join the Survey on a graded post and served the Survey for 23 years. The short history of the first hundred years of the Geological Survey records that Bose was the first to introduce into the Survey, the study of micro-sections as an aid to petrological work and the first to give descriptions of micro-sections in Progress Reports. During the period of his service, he carried out geological surveys of the Narmada Valley, of Rewa State, Central India, in the districts of Balaghat, Raipur, Mandla and Bastar, and on the Shillong plateau. He also reported on the manganese deposits of Jabbalpur district, coal in Darjeeling district and copper in Sikkim.

Bose was the first one to record the occurrence of trachyte from the Narmada region. In his classical memoir of 1883, he reported the presence of Lameta and Bagh beds and used them as marker beds for correlating similar sequences in other parts of India. He was the first to identify distinct volcanic centres around Mandaleswar in the Narmada Valley.

He took leave for two years between 15th May, 1895, and 15th May, 1897, mainly to write and see through the press his monumental work *A History of Hindu Civilization under British Rule* published in three beautifully bound volumes. Much later (in 1921) he wrote another book *National Education and Modern Progress*.

Reprinted from *J. Geol. Soc. India*, 1997, **49**, 1–5.

Resignation from the Survey

In normal circumstance, Pramatha Nath Bose, being the seniormost among the officers had to be promoted as Director of the Survey. However this did not happen. Bose has recorded – 'Indians are required to run a race with one of the swiftest peoples of the modern world on paths hitherto unknown to them but familiar to their foreign competitors'. The British government of the day was reluctant to put an Indian at the head of the prestigious Geological Survey. It held the view that it was suicidal for the Europeans to admit that natives can do anything better than themselves and that they should claim to be superior in everything and only allow natives to take a secondary or subordinate post. Holding such a view the Government of India, instead of promoting Bose appointed Thomas Holland, who had joined the Survey much later, as the new Director. Bose in protest tendered his resignation and retired from service on 1 December 1903, when he was only 48 years and still had seven more years of service. This was a bold step to take during those days and required great deal of moral courage.

Service to the iron and steel industry

The loss to the Survey was a gain to the Mayurbhanj State which immediately appointed Bose as State Geologist. This gave an opportunity to him to examine in greater detail the iron ore occurrences which he had spotted in his earlier surveys. Convinced of the richness and extent of the deposit at Gurumahisani and other nearby places in Singhbhum district, he got in touch with J. N. Tata, the great industrialist and was able to persuade him to shift the site of the steel plant which he intended to locate near Dalli–Rajhara to Sakchi (present Jamshedpur). One would have normally taken full credit for so great a discovery but not so Bose. His modesty made him say that he was only instrumental in bringing to light what had long been known to the indigenous smelters. Bose negotiated with the Maharaja of Mayurbhanj State and secured for the Tata's, a mining lease over an extent of 20 sq. miles on favourable terms. Bose had a prophetic vision and firmly believed that the firm of Tata's would before long come to be reckoned as one of the great steel producers of the world.

Bose was thus instrumental in ushering in and nurturing the iron and steel industry in India. In recognition of the services rendered to the house of Tatas, a bust of Pramatha Nath Bose was erected at Jamshedpur which was unveiled by Lewis Fermor, Director of the Geological Survey of India on 13th March, 1938.

Bose was also in the forefront of the swadeshi movement which rocked Bengal in the early years of the 20th century. He was instrumental is starting the Bengal Technical Institute in July 1906, and functioned as its Honorary Principal. A princely legacy left by Rash Behari Ghosh, enabled the Institute to shift its location to Jadavpur near Calcutta and the name was changed to the College of Engineering and Technology, Jadavpur, in 1929 and later became the Jadavpur University. Bose advocated imparting technical education based on western methods but adapted to our national needs. In his rectoral address (1914) he said

> 'We talk loudly of national progress but are oblivious of the elementary principles of such progress that a nation has to work out its own salvation by its own effort, and that the more help we take beyond a certain limit the more helpless we become.'

These words have great relevance today when intensive efforts are being made to borrow money and know-how from other countries. There can be no substitute for hard work and self-reliance.

A perusal of Bose's private letters to members of his family reveal his emotional and affectionate qualities surcharged with strong national spirit. He emphasized again and again the importance of plain living and high thinking, activated by a self-sacrificing missionary zeal, not only in religious practices, but also in social, educational and industrial fields. He was convinced about the superiority of Indian culture and exhorted his countrymen to cultivate it assiduously and not blindly copy the customs and mannerisms of the West. He deprecated the sense of inferiority which affected his countrymen and strongly urged them to feel proud of their own past.

Ranchi Ashram

Pramath Nath purchased 21 bighas of land in Ranchi in 1907 and started building a large house. He settled down to farming and the Ranchi house became an attraction to his artistic friends. His house, reverberated with music and song and the merry prattle of children and grandchildren, especially during the Pooja holidays.

In his retirement at Ranchi, Bose kept himself active, communicating his views on various matters of current interest regularly to the noted periodicals of that period – *The Modern Review of Calcutta, The Indian Review of Madras, The Calcutta Review, Prabuddha Bharatha and the Amrit Bazar Patrika.*

He was not particularly enamoured of the achievements made by the West in Science and Technology. He felt that this had only helped the promotion of militarism and forged fresh fetters on the weaker peoples. In all the development he witnessed around him he found much science no doubt, but hardly any consideration for human welfare. There was much learning but wisdom was lacking. He pleaded for rescuing humanity from the morass of militarism, malevolence, greed, selfishness and vice. His biographer, Jogesh Chandra Bagal, states that 'Service of the Motherland was the mission of his life and his pen was wielded in her cause to the last'.

Last days

Pramatha Nath enjoyed good health. He had not much faith in western medicine and never consulted a doctor. He was hopeful of completing his eightieth year and looked forward to having a grand celebration on that day. However, this was not to be. After a brief illness he passed away on the 27th April, 1934, at the ripe age of 79. The last rites were performed on the banks of the Subarnarekha river. *Amrit Bazar Patrika*, mourning his death wrote:

> '. . . at one time he was a Pucca Saheb and blind admirer of everything western. But gradually the awakening came and the Pucca Saheb became an Indian in the truest sense of the term. It was a maxim with him that if India has to attain real freedom, she must follow the great culture evolved by the *Rishis* of old and what he believed, he not only

preached and translated into practice himself.'

Connection with the Asiatic Society

The association of Pramatha Nath with the Asiatic Society extended as far back as 1883. Taking an active part in the affairs of the Society for over fifty years he wrote a monograph surveying the development of scientific research in India during the hundred year period between 1784 and 1884.

The Society instituted a Pramatha Nath Bose Memorial Medal for recognizing conspicuously important contributions to geology, with special reference to Asia. The award is triennial, the first award being made in 1950. Many eminent geologists including West, Auden, Krishnan, L. Rama Rao, Pichamuthu and Gansser have been the recipients of this award in earlier years.

'Let us pay tribute to this pioneer scientist and geologist of India, from whose work so much good has resulted.' In these words Pandit Nehru, the first Prime Minister of India, praised Pramatha Nath Bose and his services to the country. Let us not forget our early benefactors.

B. P. Radhakrishna is in the Geological Society of India, P. B. No. 1922, Bangalore 560 019, India.

PHYSICAL RESEARCH LABORATORY
AHMEDABAD 380 009

The Physical Research Laboratory makes four awards called 'Shri Hari Om Ashram Prerit Dr Vikram Sarabhai Research Awards', every two years from funds kindly provided by Pujya Shri Mota of Hari Om Ashram of Nadiad. These awards will be made to Indian scientists, who are below 45 years of age, on 1 January 1997 for original work in the following fields:

1. Space Sciences (including Astronomy, Astrophysics, Planetary and Atmospheric Sciences).
2. Space Applications (in the areas of Meteorology, Hydrology, Remote Sensing and related ground truths).
3. Electronics, Informatics, Telematics and Automation.
4. Systems Analysis or Management including non-linear, non-equilibrium systems in natural and social sciences and technology.

Although the overall work of the candidates would be taken into account, the work done in India would be given prime consideration.
The candidate should have to his credit at least one or more of the following achievements:

1. Significant achievement in scientific research.
2. Important and successful adaptation of new technology.
3. Planning, development and implementation of systems in the context of science and technology.

The selection for the year 1997 will be completed by January 1998 and the awards presented on 12 August 1998.
The last date for receiving nominations is **15 September 1997.** Sponsors are requested to send a two-page note (12 copies) summarizing the contributions and achievements of the sponsored candidate together with his/her biodata, complete list of publications (with the names of the authors in the order in which they appear in the publications), reprints of five most important publications during the last five years (6 copies) in a cover marked 'confidential', addressed to the **Director, Physical Research Laboratory, Navrangpura, Ahmedabad 380 009.**
More detailed information will be asked for by the Selection Committee, if considered necessary.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

How physicists burn their fingers

'Does steam cause a more severe burn than boiling water?' asks M. D. Deshpande (**page 235**). The chorus, from generations of teachers and students of basic physics, brainwashed by the magic words 'latent heat' would be a resounding yes. Our author's first task is to show that this standard examination question has as many holes in it as the proverbial sieve. He then draws on the accumulated wisdom of fluid dynamics (Prandtl, Reynolds, Nusselt,...) to come up with and answer well-posed versions (the plural is significant) of the same question. And lo and behold, water causes the more severe burn in all the cases. But the goal is no mere one-upmanship over the pedants. One emerges with a new respect for real world problems and their refusal to fit into simplistic academic categories. A physicist would be additionally chastened by the sharp observation that his laboratory is a wilder, more uncontrolled place than the chemist's!

R. Nityananda

Longevity and overcrowding: The case of the fruit fly

Ageing is inevitable and mortality is an inescapable fact of life. Understanding the factors that determine lifespan is the central concern of gerontologists. A grand unified view of ageing appears to be emerging as evolutionary biologists develop 'an approach that combines demography, population genetics and physiology'. Joshi and Mueller (**page 255**) use the fruit fly *Drosophila melanogaster* to address the effects of adult overcrowding on longevity. Their title points to the main conclusion – that there is an increase in age-independent mortality. This should surely strike a chord in societies struggling with enhanced population densities. The experimental protocol and statistical analysis provide clues as to the advantages of choosing the fruit fly as the subject of investigation. The authors report results which should excite the curiosity of even non-biologist readers. For instance, female flies appeared to be affected by overcrowding to a greater extent than males, showing dramatically diminished longevity. Is discrimination based on sex an important feature? The authors hasten to add 'unfortunately too much cannot be made of these differences because the early death of large numbers of females in the crowded treatment would tend to increase life span in males due to reduced courtship and mating'. The authors conclude that 'adult crowding affects longevity by altering the age-independent mortality rate rather than the rate of ageing'. For females there is the trade-off between 'fecundity and longevity'. What is the underlying physiology that is responsible for the observed effects of overcrowding? Both depletion of lipid reserves and glycogen have been considered in other studies. A more elaborate picture will emerge only when physiological and biochemical analyses of the effects of overcrowding are undertaken.

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final version in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred.) A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts, subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.).

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

CORRESPONDENCE

Monitoring India's lifescape

I was pleased to read the article 'Deploying student power to monitor India's lifescape', by Madhav Gadgil (*Curr. Sci.*, 1996, **71**, 688–697) and the painting on the cover page. The painting by Sanjeeva Nayaka was done extremely well. However, I noticed that Nayaka, for some reason or other, has missed out an important flying mammal of the order Chiroptera. These fascinating mammals known as 'bats' have existed even before pre-homosapien era. Inclusion of these creatures would have really completed the scenario on the cover page.

RIKI KRISHNAN

Bungalow No. 14,
Indian Institute of Science Quarters,
Bangalore 560 012, India

Madhav Gadgil replies:

I fully share Krishnan's affection for the bats. In fact I enjoy nothing more than watching the swarms of giant fruit bats flying over the campus of the Indian Institute of Science every evening. However, I am also fond of bugs and beetles, wolves and whales. Unfortunately it is not possible to accommodate all these creatures in a depiction such as was attempted for the cover of the November 10, 1996 issue. Therefore, we had to be content with selecting just one organism to represent each phylum. An exception was made in the case of two major phyla, namely Arthropoda and Chordata. For these we have representatives of the major classes as well. For mammals we chose a land animal – a deer, since the greater diversity of mammals prefers to walk rather than fly or swim. It was this logic that forced us to leave out bats. I hope that Krishnan would appreciate our dilemma and accept our apologies on behalf of the bats.

Extramural research funding in India – An analysis for 1994–95

Of the 1557 R&D projects approved for funding to the tune of Rs 13133.76 lakhs by 16 Central Government departments/agencies during 1994–95, Bangalore-based Indian Institute of Science tops the tally with 64 R&D projects worth Rs 873.12 lakhs. Among the top 10 beneficiaries, Delhi alone has four such organizations (Table 1) which justifies its status as the R&D capital of India (*Curr. Sci.*, 1993, **65**, 114–115). These data are contained in the latest directory of extramural projects brought out by the Department of Science and Technology (DST).

Specifically, R&D projects in the disciplines of biological (25.43%) and engineering (24.73%) sciences together account for slightly over half of the total amount. Among various categories of institutions, the universities/colleges (233) received 57.23% of the approved projects. Interestingly, only 420 organizations and 14 individual scientists shared these 1557 projects of 3–62 months' duration.

In so far as the funding profile is concerned, the DST ranks first amongst the 16 participating agencies (Table 2) both in terms of number of approved projects (458) and their total cost (Rs 4559.38 lakhs). Of these 1557 R&D projects, 721 received grants ranging between Rs 1 and 5 lakhs and only 70 projects figure in the category of Rs 25 lakhs and above. Of the four megaprojects costing

Table 1. Top 10 organizations with number of projects and total approved cost during 1994–95

Ranking	Organization	Total approved cost in Rs lakhs	No. of R&D project(s)
1.	Indian Institute of Science, Bangalore	873.12	64
2.	OPTEL Telecommunications Ltd., Bhopal	407.50	1
3.	University of Delhi, Delhi	360.21	32
4.	Indian Institute of Technology (IIT), Delhi	348.23	36
5.	Indian Institute of Petroleum, Dehra Dun	346.61	2
6.	IIT, Mumbai	329.40	44
7.	Jawaharlal Nehru University, New Delhi	293.35	25
8.	All India Institute of Medical Sciences, New Delhi	258.06	32
9.	IIT, Kanpur	245.08	34
10.	Centre for Cellular and Molecular Biology, Hyderabad	238.69	6

Table 2. Central Government departments/agencies which furnished the list of projects approved during 1994–95

Name of the agency
Council of Scientific and Industrial Research
Defence Research and Development Organization
Department of Atomic Energy
Department of Biotechnology
Department of Coal
Department of Education
Department of Electronics
Department of Ocean Development
Department of Science and Technology
Indian Council of Agricultural Research
Indian Council of Medical Research
Indian Meteorological Department
Indian Space Research Organization
Ministry of Water Resources
Ministry of Welfare
University Grants Commission

Rs 100 lakhs and above, the Department of Biotechnology sanctioned two whereas DST and the Department of Electronics sanctioned one each.

While discussing its limitations, the directory puts on record that the Ministry of Non-Conventional Energy Sources and Ministry of Environment and Forests did not furnish the list of projects for this endeavour. This is really sad. Hopefully, with the cooperation of all concerned, the future edition will provide a complete picture. It is high time that DST brought out a series of publications highlighting the research output of extramural projects to mark its silver jubilee (1971–96).

Dengue epidemic

The report on dengue hemorrhagic fever (DHF) epidemic in Delhi and the threat of yellow fever by V. P. Sharma (*Curr. Sci.*, 1997, **72**, 10 and 1996, **71**, 948) should be an eye opener to the Health Ministry and related governmental agencies. It certainly appears that this fatal viral disease (DHF) has come to stay and is likely to come back with more devastating consequences in the coming years. One logical reason for this will be as follows a) all 4 serotypes of dengue (types 1, 2, 3 and 4) have been involved in the previous 6 outbreaks in Delhi; b) population previously infected with any one serotype of dengue does not suffer from serious consequences, but when infected later with a different serotype, most likely suffers from the more fatal form of DHF which could lead to dengue shock syndrome (DSS). This was explained to be due to antibody-dependent enhancement (ADE) of viral infection (review by Halstead, *Science*, 1988, **239**, 476) which is known to occur in a number of flaviviruses to which dengue belongs. Hence a classical vaccine does not appear to be an attractive answer to control DHF. Instead, preventive measures for growth of *Aedes aegypti* mosquito are certainly the best immediate measures to control this disease. We need to learn lessons from the previous epidemics of dengue elsewhere. In Cuba, dengue epidemic occurred for the first time in 1977–78 in which 40% of the total population was infected with serotype 1 but a subsequent epidemic in 1981 due to type 2 virus resulted in DHF in which 1% of the total population (116,000) was hospitalized over a three-month period (Kouri *et al.*, *Bull. Pan Am. Health Org.*, 1986, **20**, 24). Our country is definitely not geared to take up such an emergency involving even a fraction of percentage of population. In the Cuban epidemic, children were the most affected but in the Delhi epidemic even adults were affected which warns us about the changing pattern of this disease. Apart from controlling the vector, there is an urgent need for a brainstorming session involving a cross section of expert scientists who need to act in a coordinated fashion. Instead, only a few individuals and institutes are working on shoe-string budget to battle this gigantic problem. We need to build a national resource of pathogenic organisms which need to be isolated periodically from endemic areas and epidemics and a comparative evaluation of the virus should be undertaken at the molecular level. Unlike the plague disease which at least can be cured by tetracylines, this deadly viral disease has no such drugs. Until a clear national policy is evolved for controlling epidemics, we will be helping history to repeat itself.

Organometallic chemistry of C_{60} beyond η^2-C=C co-ordination: Buckminsterfullerenes as pentahapto (η^5) cyclopentadienyl ligands

Ramaswamy Murugavel

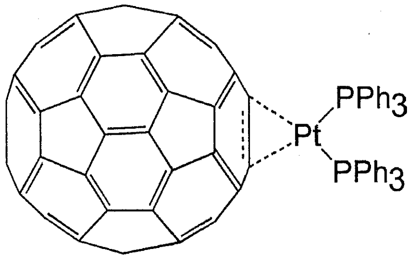
Since the initial discovery and the subsequent development of efficient synthesis of fullerenes[1], studies on the interaction of these molecules with metals have received considerable attention. This is in view of the fact that the metal-containing fullerene derivatives have the potential for the realization of new high surface area catalysts and hybrid materials with exceptional properties. Compared to the well-known chemistry of endohedral fullerenes of the type $M@C_{60}$ (ref. 2), there have been only sporadic reports in the last few years on the chemistry of exohedral organometallic complexes of fullerenes[3,4]. The initial work of Fagan and co-workers in early nineties on the exohedral organometallic chemistry of fullerenes revealed that the C_{60} molecule behaves more like an electron-deficient alkene such as tetracyanoethylene rather than relatively electron-rich species such as ethylene or benzene[3]. Moreover, the short/long bond alteration found in the six-membered rings of C_{60} suggested that each of the double bonds is somewhat electronically localized, resulting in relatively low ring currents in C_{60}. Due to these now obvious reasons, the fullerene co-ordination chemistry has been dominated by only one mode of ligation[3,4], viz. an η^2-coordination through the C=C double bonds which are located at the junction of two adjacent six-membered rings (the 6–6 bonds) as shown in $(\eta^2\text{-}C_{60})Pt(PPh_3)_2$ (A) (ref. 3).

In an important breakthrough in fullerene organometallic chemistry, Sawamura *et al.*[5] have recently described the first successful synthesis of pentahapto (η^5) co-ordination complexes of C_{60} (**2–5**) with alkali main group, and transition metals by elegantly modifying the C_{60} skeleton in terms of its electronic properties (Scheme 1).

Before going into the details of the recent findings of Sawamura *et al.*[5], a brief introduction to the η^5-cyclopentadienyl organometallic complexes is desirable. Since the serendipitous discovery of ferrocene by Kealy and Pauson[6], the organometallic chemistry of transition metals and many lanthanides has been virtually dominated by the use of cyclopentadienyl (Cp) or substituted cyclopentadienyl (Cp′) ligands which commonly co-ordinate to the metal in a pentahapto (η^5) fashion through all the five ring carbon atoms[7]. One of the main and notable reasons for the vast expansion of Cp-organometallic chemistry over the decades has been the ability of these ligands to support a wide range of metals also tolerating their various oxidation states. Moreover, the ability of the appropriately substituted Cp ligands to dictate desired electronic and steric properties on various metals has led to the preparation of a multitude of catalytically useful systems (e.g. the classical olefin polymerization catalyst Cp_2TiCl_2/Et_2AlCl) (ref. 8).

In spite of the parallel advances both in (a) the η^5-Cp-organometallic chemistry of transition metals and lanthanides and (b) the π-complex chemistry of fullerenes, until the report of Sawamura *et al.*[5], there have been no major attempts to combine these two aspects and devise routes to hitherto unknown η^5-C_{60} organometallic complexes. The main reasons for the lack of synthetic routes for η^5-C_{60} complexes can be easily discerned from the above stated findings of Fagan *et al.*[3]. The fact that the C=C double bonds of C_{60} are localized has so far precluded any possibility of using these molecules as polyhapto ligands.

In complexes **2–5**, the five cyclopentadienyl type carbon atoms are represented by one of the five-membered rings of C_{60}. This pentagon is electronically isolated from the remaining 50 sp^2 carbon atoms of C_{60} by the five surrounded sp^3 carbon atoms, each of which bear an exocyclic phenyl substituent. The key step in the synthesis of complexes **2–5** lies in the successful synthesis of the precursor C_{60} molecule $C_{60}Ph_5H$ (**1**), for which the authors have essentially used the strategy employed by Hirsch *et al.*[9] for the preparation of organodihydrofullerenes. While the



A

reactions of C_{60} studied by Hirsch *et al.*[9] with organometallic reagents such as MeLi or PhMgBr yielded the monoaddition products of C_{60}, the remarkable reaction with an excess amount of the organocopper reagent $Ph_2CuMgBr$ (prepared from PhMgBr and $CuBr\cdot SMe_2$) readily results in the 5-fold addition product $C_{60}Ph_5H$(**1**) as a reddish amorphous solid in 94% yield[5]. It should be noted that, the fullerene **1** has also been prepared by Kroto and coworkers through aromatic electrophilic substitution of benzene with $C_{60}Cl_6$ followed by the reduction of the resulting $C_{60}Ph_5Cl$ in the presence of PPh_3 (ref. 10). However, the later procedure involves a multi-step synthesis which results in somewhat lower isolated yields of **1**.

The reactions of **1** with monovalent metal alkoxides LiO^{t}Bu, KO^{t}Bu, TlOEt and Cu(O^{t}Bu)(PPh_3) yield the respective η^5-$C_{60}Ph_5$ complexes **2–5** (ref. 5). A single crystal X-ray diffraction study of the thallium(I) complex **4** reveals that the molecule possesses an aesthetically pleasing C_5 symmetry with the five Ph groups forming a chiral propeller array as shown in Figure 1. In spite of the chemical structural changes around the Cp ring, the C_{60} core in **4** largely retains its original spherical symmetry. Moreover, the average C–C single and double bond lengths in the C_{50} fragment of the molecule are found to be very similar to those found in monofunctionalized C_{60} derivatives. More interestingly, the electronic spectral data of **1** and **4** reveal that the intensity of the absorption of the 50-π-electron C_{50} chromophore ($\lambda_{max} = 240$ nm, $\varepsilon = 1.1 \times 10^5\ M^{-1}\ cm^{-1}$) is comparable to that of the parent C_{60} suggesting that the electronic properties of the compounds **1–5** are similar to those of C_{60}.

The elegant approach demonstrated by Sawamura *et al.* has truly opened up the door to the exploration of C_{60} coordination chemistry beyond its previously known limits. Carefully planned research on this type of complexes might prove useful in the discovery of a new class of fullerene-based catalysts and novel materials. Among several intriguing challenges in this direction, the preparation of metallocene complexes based on C_{60} (such as ferrocene) and other double/triple decker C_{60} complexes (which would require suitable functionalization at the diagonally opposite ends of the sphere) is likely to draw the immediate attention of the synthetic chemists around the world.

K–T meteorite relics found

While the enigma about the mass extinction of dinosaurs 65 million years ago (K–T period), whether due to terrestrial or extra-terrestrial agencies is still baffling scientists, that a 10 km wide asteroid or meteorite crashed during that period over Yucatan Peninsula (Mexico), carving the huge Chixulub crater 150 kilometers across, is not being doubted (Figure 1). Though, presumably this meteorite vapourized completely upon impacting, leaving no trace except for their extra-terrestrial signature as iridium enrichment in site-sediments, search for unburnt relics of the meteorite continued. Recently, two teams of researchers exploring for such bits, came across materials which they

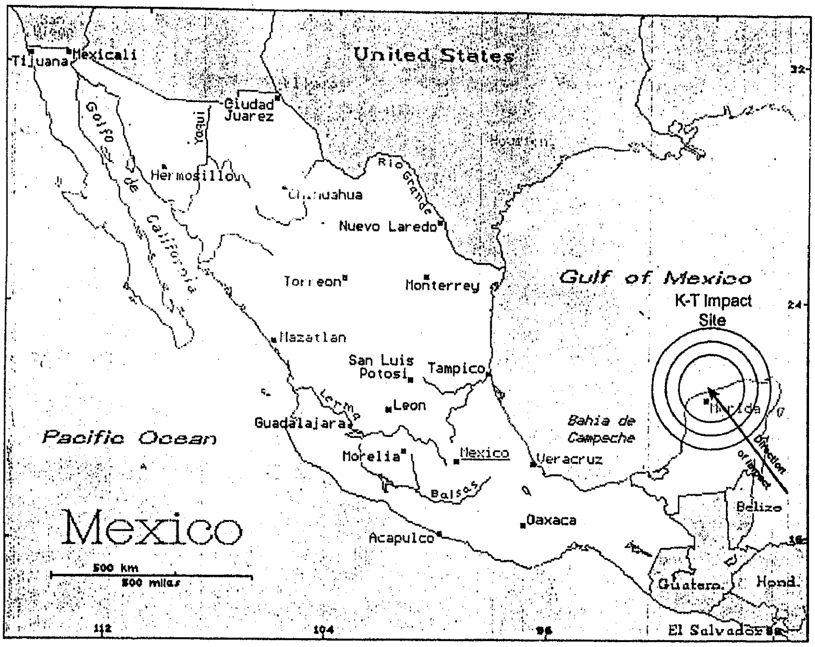

Figure 1. The K–T meteorite impact site (Chixulub Crater) in Yucatan Peninsula, Mexico.

infer were part of this K–T meteorite. One of them[1], Benjamin Schuraytz and colleagues at the NASA's Johnson Space Center, Houston, isolated from the Chixulub crater, the impact site, nuggets of nearly pure iridium enclosed inside a silicate. Apart from this, they also found iridium enriched (13.5 ppb) particles from the impact-generated melt-rock and melt-breccia and the enrichment values happened to be far above those typical of Earth's crust. They suppose that these abnormal amounts of iridium are due to admixture of meteoritic material (chondritic) into the impact melt[1], and they have estimated that at least 3% of chondritic material must have been incorporated.

The second find by Frank Kyte of the University of California, Los Angeles, has come from mid-Pacific, about 9,000 km due west of Yucatan impact site, from drill-core samples retrieved by a team drilling the ocean bed. The meteorite relic they found was a 5 mm long inclusion in a core of dark-brown clay lying at the bottom of K–T boundary layer. This inclusion contained a 2.5 mm long pebble having high amounts of Cr, Fe and Ir, in quantities characteristic of meteorites. They infer that the most reasonable source of this material, undoubtedly deposited within the K–T layers, must belong to the K–T projectile itself. This view is strengthened by the fact that this mid-Pacific site lies exactly in the path of debris that must have been thrown in a northwesterly direction when the meteorite hit Yucatan from the southeast. The impact is believed to have been made at a low angle of 20° to 30° which is considered most destructive.

A planet rotating inside Earth's womb

Seismological and computer simulation studies about the internal structure and composition of Earth, in an effort to understand the temporal variation of its magnetic field and reversal of its poles, have brought out one of its most interesting aspect – an independent spinning of the inner core, a region about the size of the moon deep in the womb of Earth.

The structure of earth into lithosphere, asthenosphere, transition zone, lower mantle and core has been largely inferred through seismic wave studies. These waves (chiefly the P and S waves, so designated on the basis of their vibration modes) travel through the Earth with different velocities, and they are affected by the density and elastic constants of the materials through which they pass. Thus, they get deflected at surfaces of discontinuity and as a result distinct subzones have been recognized within the mantle and core regions; for example, the core is made up of an outer zone about 2270 kms thick, of molten iron mixed with lighter elements and an inner one of solid iron with a radius of 1220 kms.

According to Walter Elasser and Edward Bullard, Earth's core is a self-exciting dynamo, generating its own magnetic field[1]. Here the fluid iron is 'stirred into convective motion by heat generated from residual radioactivity in the core' and in the presence of small, stray magnetic field, this motion would produce electric currents (which in turn will create its own magnetic field) just as in a dynamo where a conductor (copper wire or disc) moving through a magnetic field of a bar magnet generates electric currents. Now this phenomenon has triggered two geophysicists, Gary Glatzmaier of Los Alamos National Laboratory in New Mexico and Paul Roberts of the University of California, Los Angeles[2–4], to predict on the basis of computer simulations studies, that

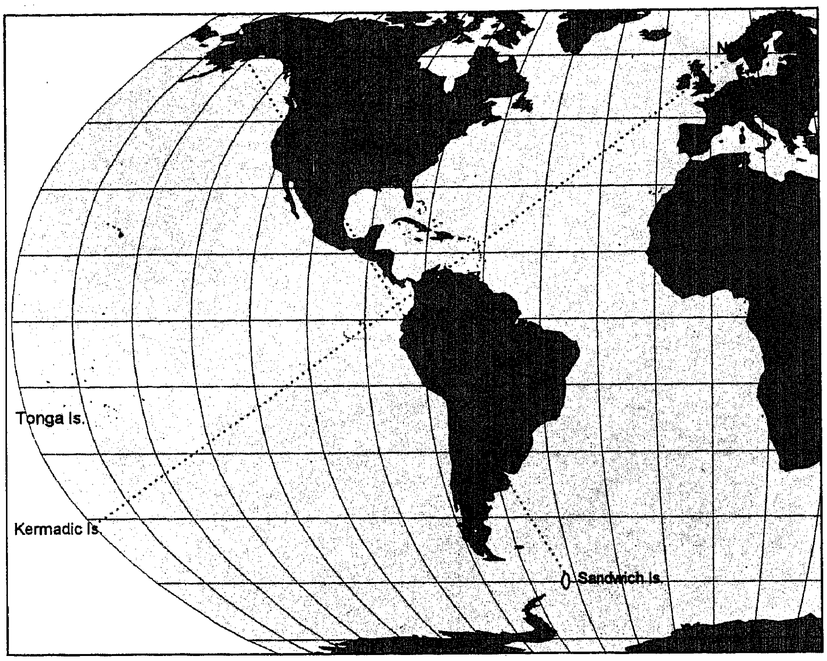

Figure 1. Earthquake focus sites and receiving stations.

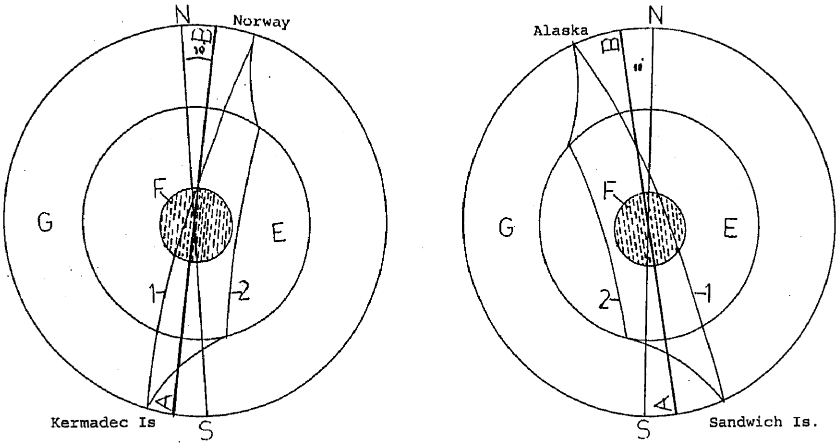

Figure 2. Idealized diagram showing drift of axis of anisotropy due to rotation of the inner core and the passage of seismic waves from earthquake foci at Kermadec and Sandwich Islands in the Southern hemisphere and arriving at the receiving stations in Norway and Alaska in the Northern hemisphere: (*left*) the position of the axis of anisotropy in 1967 and (*right*) its position in 1995. A–B, Axis of anisotropy (fast axis); N–S, North–South axis of Earth; E, outer core; F, inner core; G, mantle; (1) P-wave travelling through both the inner and outer cores, (2) P-wave travelling through the outer core only.

this dynamo action of the inner core of the Earth can induce it to spin freely. They argue that the magnitude of electric currents generated across the boundary with the solid inner core is quite huge (of the order of a billion amperes) and in the presence of magnetic field, this will exert a pulling force on the inner core. Since the outer core is viscous, they calculated that this tug will result in imparting a motion or spin to the inner core by about one or two degrees in an eastward direction.

However, according to another model developed by Arnou, Brito and Olson of Johns Hopkins University, Baltimore, this tug is caused by the powerful electromagnetic field created by stormy vortices of thermal currents raging along a north–south oriented cylindrical zone of relatively hotter outer core fluid, immediately adjoining the inner core[14].

Their predictions about the differential spin of the inner core have now been proved to be true by latest seismic studies by Xiadong Song and Paul Richards of Lamont-Doherty Earth Observatory[5]. Their observations were based on an unique behaviour of the P-wave travelling through the inner core. These waves are known to travel faster inside the inner core in the direction close to the N–S axis but slower along the equatorial plane[6,7]. This is attributed to the preferred N–S orientation exhibited by the high pressure hexagonal polymorph of iron crystals (according to one view[8], the inner core is thought to be one giant single crystal) that make up the solid inner core[9,10]. This direction, better known as the 'fast axis' or the 'axis of anisotropy', is tilted by about 10° to Earth's N–S axis of rotation[11].

Song and Richards examined all the earlier seismic data of earthquakes arising from almost the same site for several years and evaluated the time P-waves took to reach receiving stations located at the opposite sides (antipodes) of Earth (Figure 1) after travelling through (a) both the inner and outer cores (Ray 1, Figure 2) and (b) outer core only (Ray 2, Figure 2). Their examination of these earlier data pertained to the travel times of such pairs of P-waves from (i) 38 earthquakes (> 5.5 magnitude) originating from Sandwich islands (located between Cape Horn and Antartica) in the southern hemisphere and arriving at the receiving station, College, in Alaska (ii) quakes from Tonga island (mid-Pacific), and reaching Graefenberg in Germany, stations lying close to the equatorial plane and (iii) Kermadec island N.E of New Zealand, and arriving in Norway, stations lying close to the N–S axis of anisotropy. They found that while the travel times of the P-waves taking the Tonga–Germany route close to the equatorial plane, remained the same over the years, the ones that took the Sandwich–Alaska route arrived at the receiving stations 0.3 seconds sooner in 1995 than they did in 1967.

Song and Richards argue that since the paths of the P-waves through Earth are essentially fixed, their shorter travel time between Sandwich and Alaska progressively over the 28-year period can take place only if the angle between the paths of P-wave and the fast axis of anisotropy gets gradually reduced. This reduction in the angle is possible only if the inner core rotates, a feature predicted by Glatzmaier and Roberts earlier. The inferences deduced by Song and Richards from past seismic recordings were further strengthened when they noticed that the travel time between Kermadec and Norway, stations which were initially close the fast axis of anisotropy, showed an increase with the passage of time, a clear indication that these two stations are no longer close to this fast axis (Figure 2). Their calculations indicate that the 'inner core rotates about the N–S axis like the rest of the planet, but at a rate that is 1.1° faster', eastwards.

However, subsequent work by Wei-Jia Su and his colleagues from Harvard and University of California, Berkeley, evaluating a 29-year data from International Seismological Centre (1964–1992) has revealed that the inner core rotates about 3° per year faster[12].

The differential spin of the inner core was, in fact, envisaged as early as 1986 and 1989 by the Indian scientist J. J. Rawal, Nehru Planetarium[13], Bombay, as an outcome of the progressive slowing down of the spin of the Earth, a view endorsed later by Raymond Jeanloz, University of California, Berkeley. They felt that this slowing down is due to friction caused by lunar and solar tides and that this deceleration is not fully transmitted to the inner core owing to the existence of a fluid zone of outer core separating it from the rest of the planet. According to Jeanloz, the inner core is rotating presently at a rate Earth's surface was doing some 60,000 to 100,000 years ago.

These findings about the inner core rotation can have great bearing on our understanding of the physics and chemistry of the core, particularly about the outer core viscosity, its temperature and melting conditions, heat flux across the core–mantle boundary, about the dynamo action, geomagnetic reversals and the precession of equinoxes.

Does steam cause a more severe burn than boiling water?

May be not necessarily. This question is making rounds of our high schools and examinations and has even entered the popular science literature. Often it is posed in such a way that we are not asked to choose whether it is right or wrong but to explain why it is so. The *expected* answer, we know, is that steam causes a more severe burn due to the high latent heat of evaporation.

The question whether steam causes a more severe burn than boiling water is vague and ill-posed and strictly speaking cannot be answered. But what is being done here is to see how far can we rationalize this question and push analysis to understand the related issues. This exercise should also warn us while posing similar *clever* questions.

Steam and boiling water can exist at varying temperatures but it is only correct to assume here that both are at the same temperature. But this aspect is not as simple as it appears. We may have them at the same temperature at the source, but that does not necessarily mean that they will be at the same temperature when they contact the skin to cause a burn. This problem will be discussed later.

Water indeed has an impressively high latent heat of evaporation $H = 2.257 \times 10^6$ J/kg at 100°C and this aspect must have led some science teacher to coin this question. It is quite possible that the question has been

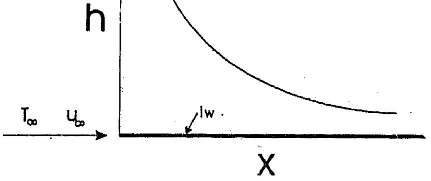

Figure 1. Heat transfer coefficient *h* due to flow along a flat plate.

Table 1. Properties of saturated water and dry steam at 100°C at one atmospheric pressure

Reynolds number $Re = v_0 d/\nu$
Prandtl number $Pr = \mu C_p/k$
Nusselt number $Nu = hx/k$ or hd/k

reinvented. Luckily the expected answer has been uniformly the same. But this innocent-looking question fits into a class where only qualitative arguments are used while completely ignoring other important aspects that are involved. The experimental observation is usually ignored or selectively chosen to strengthen the proposition.

The severity of a burn depends on the high temperature to which the skin and the flesh are raised, how long this temperature is held and the area (or volume) of the affected body. The temperature of the affected area will be higher if heat is supplied at a higher rate and also if it diffuses away at a slower rate. If a hot fluid (water or steam) comes in contact with skin, several factors decide how much it affects the skin – the temperature, density, velocity, thermal conductivity, specific heat, latent heat, how much fluid is there and whether it is replenished, how long it is in contact, etc. A droplet of boiling water that falls on the skin quickly loses its heat and cannot cause much damage but a larger volume of it can cause a severe scald. Thermal properties of the skin and the surrounding tissue also play an important role.

Now a quantitative comparison is made for two simple model problems to understand *the interplay of various factors.*

Flow over a flat plate

This simple model is considered for comparison between heat transfer when either water or steam at temperature $T_\infty = 100°C$ flows with velocity u_∞ over a semi-infinite flat plate held at temperature T_w. The distance along the plate x is measured from the leading edge as shown in Figure 1. In the case of human skin $T_w = 34°C$. We assume that the flow remains laminar without becoming turbulent. Even though the steam is bound to condense on the plate, we ignore it at this stage to study the effect of other factors involved.

Heat flux q (in W/m^2) is given by

$$q = h\Delta T,$$

where h is the average heat transfer coefficient and $\Delta T = T_\infty - T_w$ is the temperature difference which may be taken to be 100–34 = 66°C. Reynolds number Re_x (see Table 2) and Prandtl number Pr affect h which is usually expressed by proper scaling in terms of the Nusselt number $Nu = hx/k$. Expressions for Nu for different problems are available in the books on convective heat transfer. From the expression for Nu for the present laminar boundary layer case we obtain

$$h = 0.664\ (k/x)\ Re_x^{1/2}\, Pr^{1/3}.$$

The value of h decreases as one moves along the flow as shown in Figure 1. The singularity at $x = 0$ is integrable and also does not cause any problem for comparison purpose. We use suffix w for water and st for steam. The heat transfer coefficients h_w due to water and h_{st} due to steam can be compared at the same location:

$$(h_w/h_{st}) = (k_w/k_{st})((Re_x)_w/(Re_x)_{st})^{1/2}\ (Pr_w/Pr_{st})^{1/3}.$$

Now k and Pr are fluid properties but Re_x is a flow property since it depends on u_∞ and x also. Then to make a comparison we have to know the values of Re_x in both the cases. We consider the two cases here – same u_∞ or same Re_x.

Case I. Comparison for same u_∞

If u_∞ is the same for the two cases of either water or steam flowing, then Re_x scales like $1/\nu$ leading to

$$(h_w/h_{st}) = (k_w/k_{st})(\nu_{st}/\nu_w)^{1/2}\ (Pr_w/Pr_{st})^{1/3}.$$

Substitution of values for fluid properties from Table 1 gives

$$(h_w/h_{st}) = (28.2)(8.4)(1.18) = 280.$$

This means that heat transfer rate is higher in case of water by a factor of 280. This factor is due to higher conductivity of water (28.2 times), higher kinematic viscosity which is due to higher density (8.4 times) and higher Prandtl number (1.18 times). Of course, we have avoided the question of latent heat for the time being.

Case II. Comparison for same Re_x

We take another case here where Re_x is assumed to be the same in both the cases. This case is selected because of its simplicity. Then

$$(h_w/h_{st}) = (k_w/k_{st})(1)^{1/2}(Pr_w/Pr_{st})^{1/3} = (28.2)\ (1)\ (1.18) = 33.2.$$

Here high k and Pr of water lead to 33.2-fold increase in heat transfer as compared to that due to steam. Note that to maintain the same Re_x, steam has to move much faster – by a factor $(\nu_{st}/\nu_w) = 70.9$. Even then water can burn the skin more severely, if we ignore the latent heat of condensation.

The case of jet impingement

Here we assume that a jet of fluid (boiling water or steam) with velocity v_0 impinges on a flat plate, modelling the skin, as shown in Figure 2. The jet has a diameter d and its exit is at a distance Z from the plate. S is the stagnation point and we compare heat transfer in the neighbourhood of this point. Suffix '0' is assigned to the values at this point. The Nusselt number at this point $Nu_0 = h_0 d/k$. Nu_0 depends on the non-dimensional parameters Re, Pr, Z/d. It also depends on other parameters like turbulence level in the jet, nozzle shape and the boundary conditions at the wall and has the form

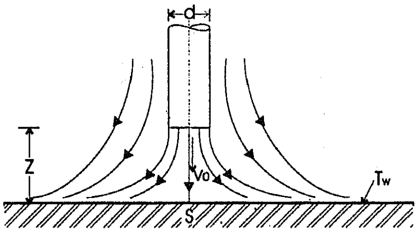

Figure 2. Jet impingement on a wall.

$$Nu_0 = CRe^n Pr^{0.4} (Z/d)^m.$$

An essential difference between the two jets should be mentioned here. The above expression pertains to a fluid jet immersed in the same fluid. Hence it can be a reasonable approximation for steam jet immersed in air or water jet immersed in water but not water jet immersed in air. There are reasons to believe that a water jet in air leads to a higher value of Nu_0 than when immersed in water and hence in what follows Nu_0 will be an underestimate if we take the same expression for water jet in air also. V. Krishnamoorthy has done extensive experiments to quantify Nu and has determined the constants C, n and m as functions of other parameters. I borrow the constants from his results but do not particularly bother to read these constants very precisely, since the final comparison and the arguments are not sensitive to them and also because of the uncertainties involved in the parameters of the problem. Taking $Z/d = 10$ and $Re \approx 10{,}000$ we get from the above mentioned experimental data $m = 0.5$, $n = 0.5$ and $C = 0.2372$. Then

$$Nu_0 = 0.75\ (Re)^{0.5}\ (Pr)^{0.4}$$

or

$$(h_0)_w/(h_0)_{st} = (k_w/k_{st})(\nu_{st}/\nu_w)^{1/2} (Pr_w/Pr_{st})^{0.4}.$$

Equipped with this expression, we follow the same procedure as in the case of flow over a flat plate – ignore condensation from steam and then take up two cases:

Case I. Comparison for same v_0

$$(h_0)_w/(h_0)_{st} = (28.2)\ (8.4)\ (1.215) \approx 288.7.$$

Case II. Comparison for same Re

$$(h_0)_w/(h_0)_{st} = (28.2)\ (1)\ (1.215) = 34.3$$

As mentioned before, steam jet velocity should be 70.9 times water jet velocity to maintain equal Re. In either case the factor 28.2 is due to high k_w, 8.4 due to low ν_w which is due to high ρ_w and 1.215 due to high Pr_w.

Steam jet impingement with condensation on wall

Let us try to estimate the effects of latent heat now and see by what factor it enhances heat transfer to the plate (skin). Condensation on the skin is a complicated process but we will make a simple assumption here that allows us to calculate this. Let

Q = Flow of heat energy in steam above skin (plate) temp. (in W)

$$= (\rho v_0 A_j)\ (\Delta T) C_p,$$

where $A_j = \pi d^2/4$ = jet exit area, m = mass flux $= \rho v_0 A_j$ and

q = Heat flux to the plate (in W/m^2)

$$= h\Delta T.$$

In the expression for Q, we have ignored the latent heat term since Q is a reference value from no condensation case. If we consider $A = \pi d^2/4$ as a reference area on the plate which is equal to the jet exit area (it is by no means critical),

$r = qA/Q$ = fraction of heat energy of jet transferred to this area.

Now the assumption is that the same fraction r of m is going to condense on this reference area A. Then the condensed mass flux $m_{\text{cond}} = rm$ (in kg/s), and the heat flux due to latent heat by steam condensation

$$q_{\text{cond}} = m_{\text{cond}} H/A = rmH/A.$$

Substituting the proper expressions and the numerical values

$$q_{\text{cond}}/q = H/(\Delta T C_p) = 16.47.$$

This ratio means that heat released due to condensation is about 16 times the heat transfer from steam if there were no condensation, other parameters being the same. This factor even though looks large is still smaller than the ratio $h_w/h_{st} = 34.3$ for even the case of same Re. For the same water and steam velocity h_w/h_{st} has a much higher ratio of 288.7.

More about condensation

We have purposely avoided till now considering details of the process of condensation itself. Even in the previous section an *ad hoc* assumption was made. Condensation depends on several factors and hence a direct comparison for the present purpose is not possible. Condensation on a surface takes place is the surface temperature is below the saturation temperature of the vapour. If the condensed liquid wets the surface, like water on skin, film condensation takes place, as against dropwise condensation. Dropwise condensation leads to a higher heat transfer rate. In either case the latent heat of condensation is imparted to the surface. The surface temperature goes up unless it is taken away by conduction or other means.

If steam at saturation temperature T_s condenses on a plate at uniform and steady temperature T_{wall}, a liquid film develops on the wall. The interface between the liquid film and steam is at temperature T_i which is only slightly lower than T_s. The rate at which condensation heat transfer takes place by film condensation on a vertical plate is given by the Nusselt formula

$$h_f = \left[\frac{g\rho_w k_w^3 H}{4\nu_w (T_i - T_{\text{wall}})Z}\right]^{1/4}.$$

Here Z is the distance measured down from the top edge of the plate.

For the interfacial heat transfer (which should be equal to the transfer in the film to the wall in the 1-dimensional model) we have the expression

$$h_i = \frac{q}{T_s - T_i} = \frac{2\sigma}{2-\sigma}\frac{H^2\rho_{st}}{\sqrt{2\pi R T_s^3}},$$

where R is the gas constant for steam and σ is the condensation coefficient. It may be mentioned that inert gases like air mixed in the vapour greatly inhibit condensation and hence heat transfer. Since $h_i >> h_f$, the total resistance to condensation heat transfer

$$\frac{1}{h_{\text{cond}}} = \frac{1}{h_f} + \frac{1}{h_i} \approx \frac{1}{h_f}.$$

Then,

$$h_{\text{cond}} \approx \left[\frac{g\rho_w k_w^3 H}{4\nu_w (T_s - T_{\text{wall}})Z}\right]^{1/4}.$$

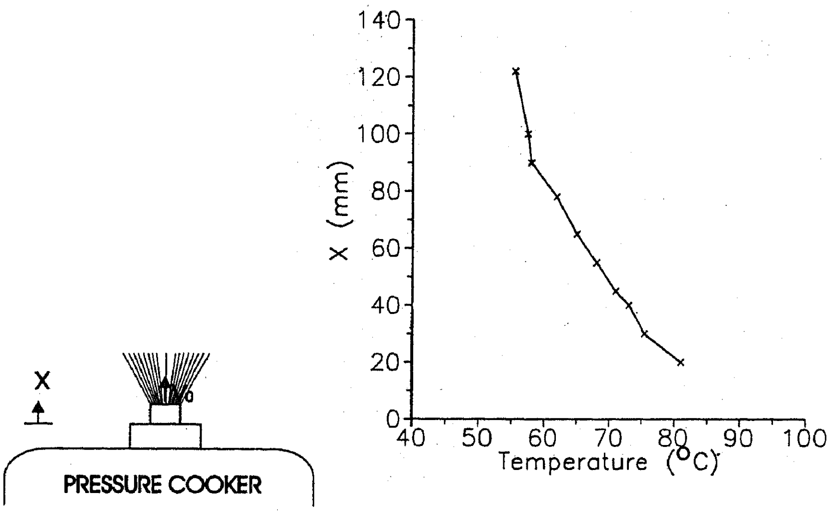

Figure 3. Temperature along the axis of a steam jet of 5 mm exit diameter.

This has a singularity at $Z = 0$ which is a modelling artefact. Getting an average value of h_{cond} by integrating up to a length L,

$$\bar{h}_{\text{cond}} = \frac{4}{3} h_{\text{cond}}(L).$$

For $Z = 0.01$ m, we get $\bar{h}_{\text{cond}} =$ 12,850 W/(m^2°C).

See that it is not easy to compare it with the boiling water case unless we have all the details in both the cases, since the actual value depends strongly on the details. For the flow over a flat plate case, for example, $\bar{h} = 2h(L)$. Substituting the values for water we get $\bar{h} = 2{,}003\sqrt{u_\infty/x}$. If we take $u_\infty = 1$ m/s and $x = 0.01$ m, we get $\bar{h} =$ 20,030 W/m^2°C. Different accident models and numerical values lead to heat transfer rates where either case may have a higher value.

The actual case when the skin is exposed to steam is an unsteady one. To start with, there is no film of condensed water and hence the skin is exposed to a very large heat transfer given by the coefficient h_i above. But it is only for a very short time and the thin film of water formed retards the heat flow. As it gets thicker its resistance increases and also since the skin is getting hotter the temperature difference causing the heat flow decreases. The formula given above for numerical estimation pertains to the steady state case. But see that when the steady state is reached, the temperature difference will be much smaller than 66°C.

What does it mean?

Since the question posed was vague, we have tried to rationalize it, as best as it can be done. Latent heat of steam is very high. (A feel for the very high latent heat of evaporation of water can be obtained by calculating the ratio $H/C_p = 535$°C. Thus only one gram of steam condensing in 535 g of water can raise its temperature by 1°C.) But there are other factors too. Water has high thermal conductivity and density (hence low kinematic viscosity). Because these aspects counteract, a quantitative analysis is required. This is done by modelling and we see that for the jet impingement problem the heat transfer from boiling water is much higher than that from steam at the same temperature, provided steam does not condense. The amount of steam that condenses has been obtained by making some assumptions. Then heat transfer from the condensing steam increases by a factor greater than 16. This factor, even though large, is still smaller than for the case of heat transfer from boiling water.

A word of caution is required here. We should not take these factors literally because of the assumptions involved. The two factors 16.47 and 34.3 are not really far apart. They indicate that it is possible to adjust parameters so that the first factor (16.47 here) can even be greater than the second one, i.e. condensing steam does cause a more severe burn. But it does not always happen.

The factors calculated in the two model problems (Laminar flow over a flat plate and turbulent jet impingement) turned out to be almost the same for similar conditions. This indicates that the present comparison is not sensitive to the mathematical model used. But it should be noted that it is true only for a comparison for similar conditions. The value of heat transfer, on the other hand, depends very strongly on the magnitudes of the parameters like fluid temperature, fluid mass involved, contact time, mass and rate of steam condensation, fluid velocity, whether the flow is laminar or turbulent, etc. The accident causing a burn is likely to be an unsteady process of a short duration, the values of the parameters being peculiar to each case. *That is why modelling this problem and drawing any general conclusions are not possible.*

On the other hand, there are some aspects on which we may comment. Steam jet usually has a higher velocity than that of a water jet. Water sticks to the body (unlike steam) thereby causing a longer contact. Steam that is issuing out in the form of a jet expands when it comes out and later the ambient air mixes with it which is called 'entrainment'. The entrainment cools the steam jet. This is shown in Figure 3 where I have plotted the temperature along the axis of a steam jet of 5 mm exit diameter. The steam jet was created from an ordinary pressure cooker by removing the weight. The bulb of the thermometer used was rather large and hence the measured values of temperature are likely to be lower than the actual values, the errors being larger closer to the exit (small X). Despite its crudeness, the experiment is adequate for the present demonstration.

Hot tea (temp ~60°C) can cause a severe burn (believe me). But how is it that we drink it and even enjoy its warmth? It is because we have mastered taking a sip that comes in the form of a sheet and gets cooled by air before coming in contact with the lips. Try drinking it with a straw; but be careful, you may burn your tongue.

It has not been verified experimentally or otherwise that steam causes a more severe burn than boiling water. But such notions persist because we get conditioned at a weaker moment, say when we study a chapter on latent heat. To remove such an ill-founded question, even though there is no supporting evidence, from mass circulation is not easy. It is because of the difficulties involved in getting a convincing quantitative answer when several factors are involved.

The problem we are discussing may sound innocent, specially because the *expected* answer sounds convincing, is simple to give and is uniformly accepted. A more serious problem is faced by undergraduate students while conducting experiments involving physical systems. Often there are many parameters that contaminate the experiment. The students do not have a good understanding of these extraneous factors, leave aside a good control over them in the experiment. These become a more serious handicap than the inaccuracies in the instruments. But the students are obliged to get an 'expected' answer and often 'cook up' the results. Experiments in the chemistry curriculum, in my experience, are usually better controlled and one becomes confident after successfully getting the answers.

Coming back to the question on burns, it is not always simple to decide which of the two burns is more severe. And regarding the problem we are discussing, I checked with a couple of doctors what they have in the medical literature. They do not bother whether the burn is caused by steam or water. They go by a different classification of the burns. Probably they are forced to be more honest since there is a serious problem in hand.

It may be interesting to mention here about the damage due to cold where the heat is extracted from the body. Air at 1°C makes us uncomfortable but we can survive it. But a human being in water at 1°C cannot survive it for more than 30 minutes. This is because of higher density, thermal conductivity and specific heat of water as compared to those of air. The question of latent heat does not arise here.

Does steam cause a more severe burn than boiling water? It may; it may not also. The question is not proper. I do not give an answer, but I have an explanation.

ACKNOWLEDGEMENTS. I thank my colleagues Dr P. N. Shankar and Dr V. Krishnamoorthy and an anonymous referee for making helpful suggestions and Mr V. S. Narasimhan for the help rendered in preparing the figures.

Remote sensing application for delineating coastal vegetation – A case study

Satellite remote sensing has progressed rapidly and has provided a wealth of information on land as well as near-shore regions due to its repetitive and synoptic coverage. Remote sensing data have been used extensively worldwide for mapping coastal vegetation[1-3]. Similar work, however, along the Goa coast, is reported to a lesser extent[4,5].

This study envisages the use of digital image processing techniques for delineating geomorphic features and associated vegetation, including mangrove, along the central part of the Goa coast which includes the Mandovi–Zuari estuarine complex (Figure 1).

The typical geomorphological features, supported by favourable water currents and salinity, decide the lateral growth of coastal vegetation. Hence, identifying suitable geomorphic sites along the coast and the estuaries is a major task in depicting and delineating the vegetational features.

Multi-spectral scanner (band 4,5,6,7) data pertaining to scene (Path 49, Row 142) dated 31 March 1986 of Landsat 5 were used. Sub-image (Figure 2) with 900 lines and 900 pixels, covering Mandovi and Zuari estuarine complex, was separated and digital processing was carried out using DIPIX image processing system.

Because the influence of the coastal features on each band is highly correlated, compressing all bands into a single plane improves the identification of individual features. For this purpose,

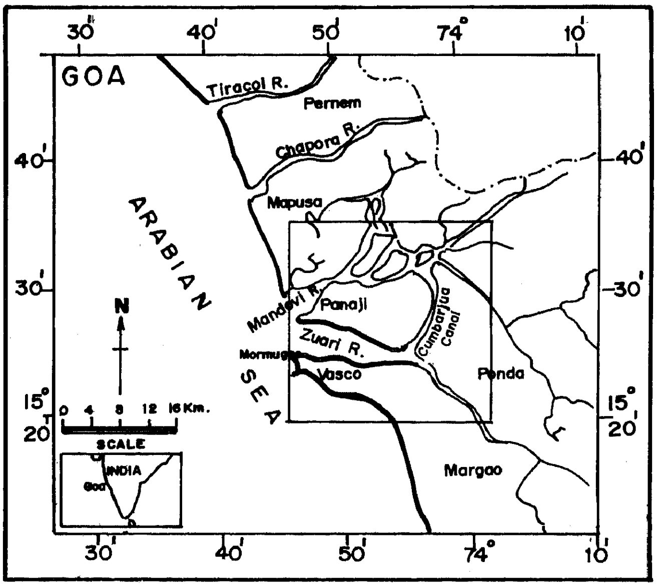

Figure 1. Location map of the study area.

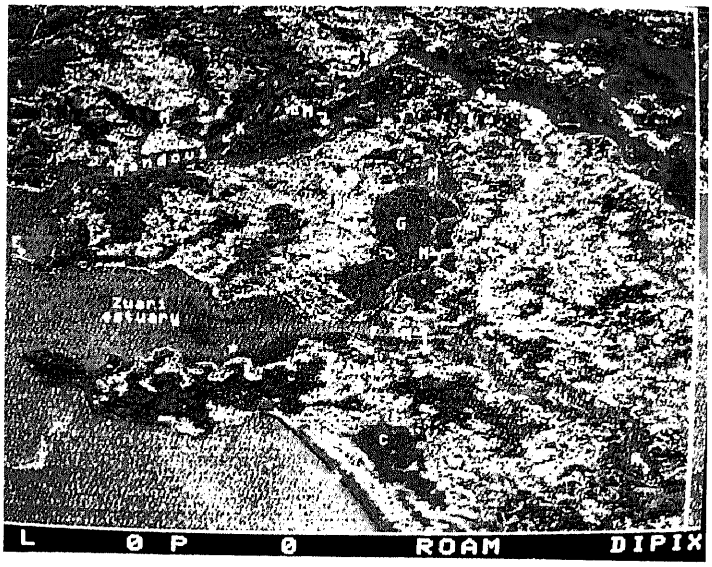

Figure 2. Colour composite image of first three principal components – PC1 (blue), PC2 (green), PC3 (red). The image shows some of typical sites of the following features. A, Green dense vegetation; B, Thin vegetation; C, Uncultivated field; D, Sandy beach; E, Rocky island; F, Sand bar; G, Mud flats; H, Water-logged body; I, Vegetated river terrace; J, River terrace devoid of vegetation; K, Point bar; L, Submerged land; M, Typical mangrove vegetation sites.

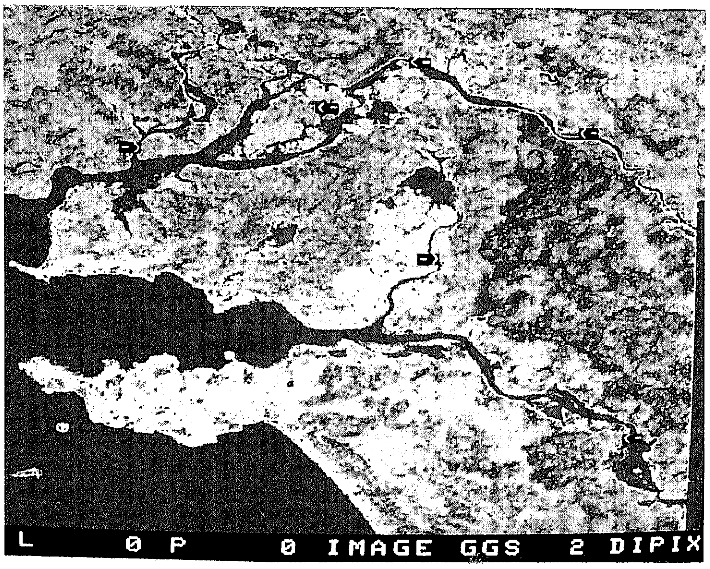

Figure 3. Intensity-modulated pseudo biomass index image showing typical mangrove sites (directed arrows).

Principal Component Transformation – digital processing of four spectral bands – was performed to produce four new Principal Component (PC) images[6]. Feature images of PC1, PC2, PC3 and PC4 were created on the monitor and photographed. False colour composite was generated from the first three principal components on the monitor and were photographed for visual interpretation.

Intensity-modulated pseudo biomass index image was generated by subtracting radiance values of 5th band from the radiance values of 7th band and dividing this by total radiance in both these bands. Three separate files were created by stretching and distributing gray values as described by Donker and Mulder[7], and stored using the same look-up table. The primary colours red, green and blue were assigned to first, second and third files respectively and finally Intensity Modulated Pseudo Colour Biomass Image was created and photographed.

All image enhancement products which include false colour composite, colour composite of PCs, intensity-modulated pseudo colour biomass and first two principal components images PC1 and PC2 were visually interpreted on the basis of tone, colour, texture and their association with other features. Shore line, estuaries and inter-tidal zones were extracted from the colour composite image. River terraces, mud flats, sand bars, point bars, meander bars, beaches, etc. were mapped from the PC colour composite image (Figure 2). These units showed reddish colour if barren and violet if they were wet. Vegetation on PC composite image is noticed by yellow green (spares) through green (dense) colour. Red colour in biomass index image marks the appearance of vegetation. The density variation was noticed on the basis of texture and colour shades, red (dense vegetation) to red spots on yellowish background (thin vegetation) (Figure 3).

Mangrove vegetation is extensive in the estuaries of the Mandovi and Zuari rivers, particularly in the silted-up fringes of the Cumbarjua Canal (Figure 3). Above the tidal limits, wherever the elevation allows beach formation, typical beach flora occur with shrubs and maritime grasses along with coconut plantations (site 'B' in Figure 2). This beach flora appears as a thin red line alongside the beaches, which appear as yellow strips on biomass image (Figure 3).

When the findings from the satellite data were compared with aerial photos (1960, 1:15,000 approx. and 1973, 1:25,000 approx.) and recent Indian Remote Sensing Satellite (IRS) images (path 96, row 62, L3 dated 5 April 1996) visually, it was noticed that small islands along the rivers are growing peripherally due to heavy siltation. Alluvial deposition along the banks of rivers have converted parts of bays into swamps. It is possible that the sediments are mainly derived from the inland mining rejects, and from heavy erosion due to deforestation in catchment areas of the rivers. These sediments are transported downstream as suspended matter. Under favourable hydrographic conditions, the sediments flocculate near the islands of low lying areas and give rise to submerged mud banks. As the sedimentation continues, these mud banks grow above the high tide level and are subsequently stabilized when floating vegetation hold the roots. Such mud banks thus form favourable ground for the luxurious growth of vegetation.

It is concluded from this study that i) repetitive coverage and spatial resolution of space borne data permits us to locate recently deposited alluvium and change in vegetation; ii) though constant biotic pressure is severely degrading the coastal vegetation, there are a few locations, where recent alluvium has deposited, forming favourable grounds for growth of vegetation.

A rapid method of estimating essential oil content in heartwood of *Santalum album* Linn

Sandal (*Santalum album*) tree is mainly exploited for its scented heartwood which gives fragrant sandalwood oil upon steam distillation. Oil yield varies from 2.5 to 6.2% depending on age of the tree, soil, climatic and genetic factors. Fixative property and tenacious aroma of sandal oil are due to its major odoriferous sesquiterpenic constituents – alpha and beta santalols, forming about 90% of oil. However, alpha and beta santalenes and santalyl acetate which form about 6% of the oil also contribute to some extent to the overall characteristic odour of oil[1-4].

Sandalwood oil is generally obtained by hydro or steam distillation of powdered heartwood. A minimum quantity, 50 g of heartwood powder, is required for estimation of oil content. Estimation of oil in a small quantity of heartwood powder is difficult by the conventional steam distillation method. Two laboratory methods based on colour of wood and electrophoretic technique were developed earlier. In the first method, the colour of heartwood powder, whether light brown, yellow, brown or dark brown was determined by a tintometer and correlated with oil content[5]. Peroxidase isoenzyme activity in living bark tissue was determined by polyacrylamide gel electrophoresis and used as a marker in the second method[6]. Determination by tintometer method requires clear physical distinction of colours of heartwood powders and sometimes distinguishing colours of heartwood material in core samples taken from standing trees was found difficult.

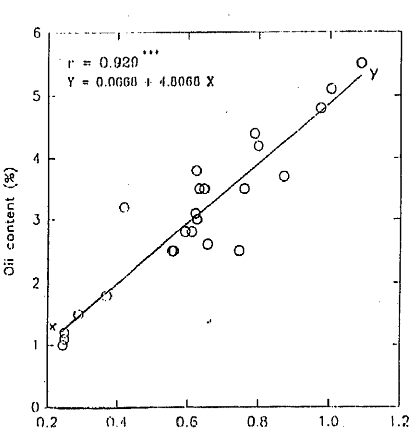

Figure 1. Relationship between oil content and optical density of hexane extract of sandalwood powder.

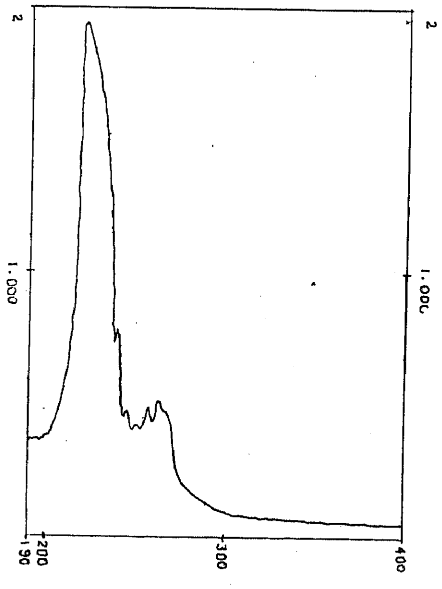

Figure 2. UV spectrum of sandalwood oil (25 mg/100 ml).

0.555	2.5	2.7

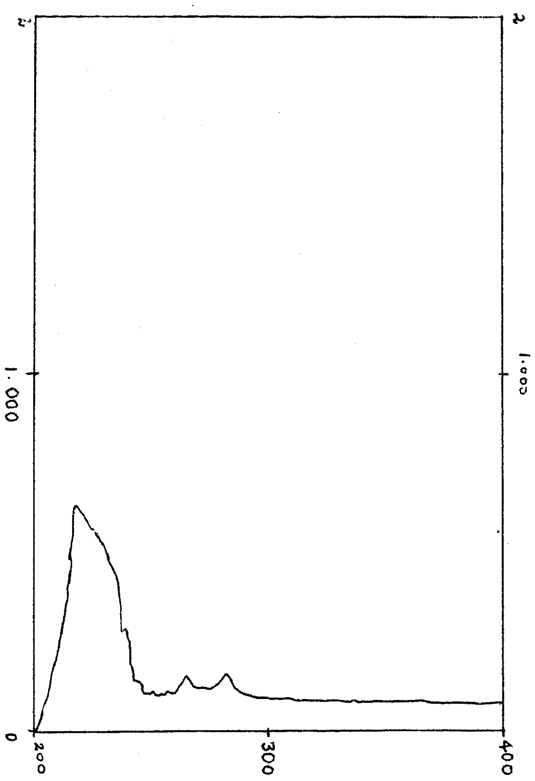

Figure 3. UV spectrum of hexane extract of sandalwood (100 mg sandal powder/100 ml).

Determination by polyacrylamide gel electrophoresis is based on enzyme activity of living bark tissue, which needs to be estimated within a few hours of sample collection which is not feasible when the collector of samples is on tour. The method highlighted in the current paper however, can be carried out later in the laboratory at any point of time after the sample collection. Also this method is simpler and quicker than the other two.

In the present study, estimation of sandal oil in a small quantity of heartwood material containing atleast 1 mg of oil is rendered simpler, quicker and fairly accurate by using UV spectrophotometer, measuring optical density (O.D) at 219 nm (max) on hexane extract of sandal powder, whose oil content was predetermined by steam distillation method.

Twenty-five samples of sandalwood were selected from sandal depots of Karnataka and Tamil Nadu at random. Heartwood was powdered after separation of sapwood and bark. 100 mg of heartwood powder was taken in 100 ml volumetric flask, hexane (60–70°C) was added up to the mark and kept aside for 18 h with periodic shaking. The supernatant was taken in quartz cell and OD at 219 nm (max) was measured by UV spectrophotometer (SHIMADZU-240). Oil content in the same sample of wood was also estimated by steam distillation of 100 g of powder separately. By keeping the heartwood powder in hexane for 18 h, it was found that the extraction was exhaustive and durations less than 18 h were found to be insufficient. The results are presented in Table 1.

Oil content was related with OD (Figure 1) by the regression equation

$$Y = 0.0668 + 4.8068\,X$$
$$(X = \text{Optical density})$$
$$Y = \text{Oil content (\%)}.$$

There was a highly significant and positive correlation between O.D and oil content ($r = 0.929$). UV spectra of sandalwood oil (25 mg/100 ml hexane) and hexane solution of one of the sandalwood powders at 219 nm (max) are presented in Figures 2 and 3. It is concluded that this method would be useful in rapid screening of sandal plants for their oil content and in selection of plus trees among different provenances.

A more refined method to identify core institutes: A case study of biomass research

M. C. Shukla, S. Saksena and M. R. Riswadkar

Core institutes engaged in research on a given topic are those that contribute the most to published literature on that topic. As such, it appears easy enough to identify the core institutes: all one needs to do is to scan one or more abstracting services that cover the research field in question, note the institutional affiliations of authors, and prepare a tally – when the institutes are arranged in decreasing order of the number of papers contributed by them, we get a ranking order. However, in practice, the procedure turns out to be less straightforward.

IDENTIFICATION of major institutions engaged in biomass research the world over, and in India in particular, was one of the objectives of this study. The purpose of this exercise was to identify the institutions that have been actively contributing to the body of literature in biomass, in the period under investigation. Specifically, the top 50 institutions were to be listed and ranked. An exercise of this kind, it is hoped, will help in identifying institutions that are contributing extensively to the advancement of knowledge. The strategy used to achieve this objective is outlined below.

Conventionally, author-affiliation is used to identify major institutes/organizations. However, using author-affiliation as reported by the abstracting services has two disadvantages: (1) each abstract may not always provide complete affiliation (in the present study, the percentage of entries giving complete affiliation was not the same for each service *[Biomass Abstracts (BA), Chemical Abstracts (CA), Energy Abstracts (EA), Energy Abstracts for Policy Analysis (EAPA), Energy Research Abstracts (ERA), Forestry Abstracts (FA), Fuel and Energy Abstracts (FEA), Forest Products Abstracts (FPA), Indian Energy Abstracts (IEA), and Indian Science Abstracts (ISA)]*, it varied between 80 and 97%) and (2) eliminating the same research paper abstracted by two or more services was not possible (at least in the above approach).

The question, therefore, was whether one could use the author-affiliation reported by abstracting service(s) to identify core organizations in any field of interest for a given time span. An attempt has been made in this study to examine this question and explain the rationale behind its solution. Ideally, such a ranking should be done by obtaining exhaustive lists of published literature from, say, 100 prominent institutions. The selection of these institutions could be based on experience in the subject field. This list could then be narrowed down to the required 50 institutions. This is, however, impracticable and time-consuming. An alternative method is to scan all primary sources of literature published in this period. This, too, has its obvious drawbacks. The next choice is to use the information provided by abstracting services. However, using abstracting services to arrive at such a ranking is not as straightforward a task as it seems. The reasons for this are explained below.

Rationale

An abstracting service provides abstracts of only a portion of all the literature published in a given period. The need for, and the extent of, sampling is governed primarily by the policy of the service, and space considerations. For this reason, it is not advisable to use a single abstracting service to identify the core institutions. By considering many services, the coverage is increased but a complete coverage cannot still be guaranteed. However, using many abstracting services leads to a problem, the crux of which is this: the probability that the title of a primary (paper) document will be mentioned along with the complete affiliation of its author(s) is not necessarily the same for each service. This statement is based on the realization that the appearance of the name of the institution from where a paper is contributed is dependent on two factors, both of which are governed by chance. More importantly, the magnitude of these chances is not the same in all services. These two factors can be framed as questions: (1) What is the chance that a paper (bearing the affiliation

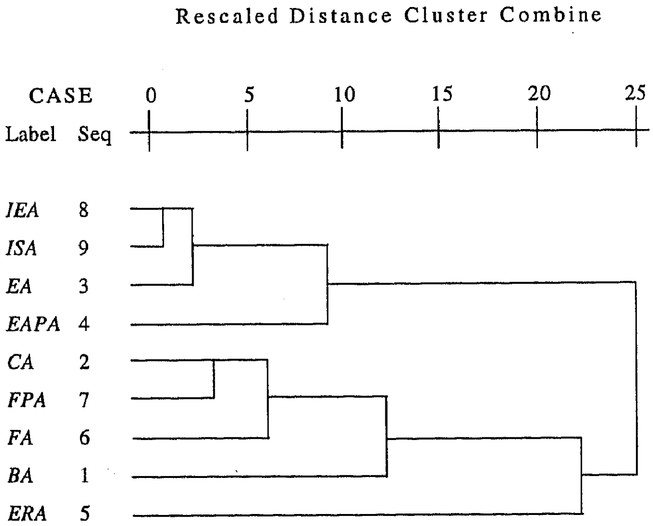

Figure 1. Dendogram using average linkage (between groups).

of the author) will be selected by a service? (2) What is the chance that, having been selected by the service, the complete affiliation will also be printed along with the abstract? If the selection of a paper is not dependent on either the service or the type of paper and if the probability of the complete affiliation of a selected paper being mentioned is the same for each service, this task would be simple: count the number of times each institution is mentioned (after eliminating duplicated records) in the sample of abstracts, disregarding the service that published the abstract. The reality is, however, different.

A simple example can illustrate what has been discussed so far. Suppose an article was published (with full affiliation) by ABC institute. The article was abstracted by two services S and T. Service S is known generally to mention affiliations in 90% of its abstracts, the corresponding figure for service T being 60%. Then it is 1.5 times more likely that one would have noticed the name ABC if one were to consult service S alone. But since abstracts of S and T are pooled, one would notice the name ABC if it is mentioned in S, or in T, or in both. The chance that this will happen is 96%. Now, consider another article published by DEF institute. It is abstracted by services M and N whose affiliation-reporting percentages are 50 and 80 respectively. By similar logic, it can be shown that the probability that DEF will be mentioned in M, or in N, or in both, is 90%. So if all the four services are considered, then the institute ABC is more likely to be mentioned than DEF, the difference in probability being 6%. The situation can get more complicated if one assumes that it is not equally likely that articles from ABC will be abstracted by services S and T. Similarly, one can assume that articles from DEF are not equally likely to be abstracted by services M and N.

There is nothing one can do to avoid the consequences of the fact that a service's coverage can only be selective and that it would be providing affiliations for only a certain fraction of the selected abstracts. But what one can do is to ensure that sets of services are chosen that consist of fairly similar services in these respects. For example, consider that 89%, 91%, and 92% of the abstracts in three services M, N, and P are those of the articles that have appeared in journals. The fraction of abstracts that carry complete affiliation is 75%, 77%, and 76% respectively in these three services. It can then be said that these three services are similar. Therefore, if two institutes – ABC and DEF – publish a journal article each, then it is equally likely that one would encounter their names. It is then immaterial which particular service published the abstract. That is, neither of the institutes will face a handicap. In other words, within a set of services there should be no comparative bias in selecting articles or reporting affiliation.

Methodology

A total of 9206 records were selected as a sample which forms 16.4% of the total output (56,240 abstracts) covering the period from 1982 to 1986 of the ten databases under examination. Stratified random sampling was employed in the case of *BA*, *FA*, and *FPA*. In the remaining seven services (*CA*, *EA*, *EAPA*, *ERA*. *IEA*, and *ISA*) original total (populations) of abstracts were taken for further analysis (Table 1).

Having selected the sample, the question that arises is: How to identify, from the ten services, those that are similar? In the present work, first the fraction of abstracts of journal articles where complete affiliation was provided by each service was ascertained. Overall, about 90% of the abstracts carried complete affiliation. There is no way of knowing how many abstracts in the remaining 10% did not record the affiliation because it was not furnished in the source document itself, and how many failed to do so during the abstracting process owing to human error, negligence, etc. It is assumed, for this exercise, that all primary source documents did carry the complete affiliation. The reporting of complete affiliation varied across the services, from 81 to 97%. A χ^2 test confirmed that reporting fraction was significantly dependent on service. By trial and error, it was possible to isolate two homogeneous sets (confirmed again by the χ^2 test) of services: one reporting affiliations to the extent of 94% and the other, 85%. One service, *EAPA*, still stood out (81%) when only journal articles were considered. It was then decided to consider all bibliographic forms and carry out a similar analysis (Table 2).

The overall reporting fraction in this case turned out to be 89%. The services showed a range from 80 to 97%. Again, it was possible to isolate two homogeneous sets. However, in this instance, *EPA* stood out (80%). It is only a coincidence that in both the exercises, the analysis yielded two sets. This then raised the question: Is use of only one criterion in forming sets of services valid? It was then decided to consider four other criteria: (1) the availability of affiliation in these services, (2) the number of journal titles monitored, (3) the number of conference titles monitored, (4) the number of languages, and (5) bibliographic forms (e.g. B for book, P for patent, J for journal article) considered by each service (Table 3).

It is hypothesized that these five factors primarily determine whether a given document will be selected for abstracting. A statistical technique, cluster analysis[1] was used to group similar services by simultaneously considering all the five criteria. The normal Z-scores of these five variables were used to prepare a 10×5 matrix for cluster analysis. The results showed that the ten services can be sorted into two homogeneous sets (Figure 1). The membership of each of these sets is also decided by cluster analysis. It would have been very fortunate if the results of cluster analysis had shown that all the services were similar and therefore part of a single set. But since

Table 3. Criteria considered for cluster analysis

Service	Availability of affiliation (%)	Journal titles monitored	Conference titles monitored	Languages considered	Bibliographic form(s) covered

that is not the case, the core institutions were identified separately with these two clusters/sets as well as with all of them pooled together.

The members of each group were also decided by cluster analysis. The three groups that were considered are: Group A: *BA, CA, ERA, FA, and FPA*; Group B: *EA, EAPA, IEA*, and *ISA*; Group C, which included all the services (excluding *FEA*). A card was prepared for each paper abstracted containing information on (i) name of the service in an abbreviated form (e.g. *BA*, *CA*) followed by year of publication and the abstract number, (ii) name of the first author followed by year of publication, (iii) title of document, (iv) source, (v) language of the text, (vi) affiliation of the first author (on

the back of the card), (vii) document type (e.g., B for book; J for journal article; P for patent), and (viii) country of the source document. For each group the cards were arranged first by country and then, within each country, by author. When names of authors were identical, titles of articles were checked. For the same research papers only one card (from any service) was retained and additional cards were kept aside. In the next stage, these cards were arranged by organization under each country. In the last stage, these cards were rearranged in decreasing order of productivity, irrespective of the country. Finally, a ranked list of core institutions (or ranked organizations) was compiled.

Results

The three ranked lists are fairly different. Group B places three Indian institutes first. SERI (Solar Energy Research Institute, Colorado; now known as National Renewable Energy Laboratory) appears in the 19th position. This cannot be the representative situation at the global level. In Group C, Forest Research Institute, Dehra Dun tops the list. Two Indian institutes are ranked at 12th and 19th positions. It is obvious that IEA and ISA have selected mostly Indian abstracts. This led to high ranking of Indian institutions. Group B thus could be used to identify the top 20 Indian institutes. Therefore, it was decided not to consider Group B for final comparative ranking. Table 4 shows comparative ranking for (1) Group A without duplicates, (2) Group C without duplicates, (3) Group A with duplicates (A′), (4) Group C with duplicates (C′).

The results show that comparative ranking does not change significantly if duplicate records are included. However, differences between Group A and Group C are significant. One can either compare the absolute values (columns 2, 3, 4 and 5) or the ranks (columns 6, 7, 8 and 9).

Comparison of absolute values using Wilcoxon matched-pairs signed-ranks test

From Table 5 it is evident that only the groups A and A′ are statistically similar. (Note that for four groups, there are six pairs that can be compared.) Groups are considered to be similar when *Z*-value is low and *p* is high.

Comparison of ranks using Wilcoxon matched-pairs signed-ranks test

By ranking the institutes it is observed from Table 6 that groups yield comparatively more similar results than for the corresponding absolute values (in each cell of Table 6, *Z*-value is lower and *p* value is higher than corresponding cell in Table 5).

It is also observed that the presence of duplicate records does not significantly alter the ranking, i.e. A′ = A and C′ = C. (Of course, duplicates create significant difference in absolute values between A′ & A.) From Table 6 it can be seen that the groups which are most similar are: A & C, A & A′, C & A′.

Conclusions

1. If absolute values of number of publications (the actual frequency distribution) are considered then it matters how one has grouped the services in order to identify major institutions.
2. If ranking is considered alone, then grouping of services is less critical. Also, duplicate records do not affect the ranks (but this is not true of absolute values).
3. The decision to select top 50 institutes out of the four groups, is to be based on experience and intuition, since Table 4 suggests that many of these groups produce similar ranking. Thus, we chose Group A (*BA*, *CA*, *ERA*, *FA*, and *FPA*). If top 20 Indian institutes are to be identified, then Group B (*EA*, *EAPA*, *IEA*, and *ISA*) can be used.

ACKNOWLEDGEMENTS. We are grateful to Mr Yateendra Joshi, TERI, for his comments and suggestions on an earlier draft of this paper. MCS thanks Dr R. K. Pachauri, Director, TERI, for granting one-year study leave and for the permission to use TERI resources.

Fossil woods and their significance

J. S. Guleria and N. Awasthi

Fossil woods are the most striking and frequently occurring megaplant remains in sedimentary rocks. They store a wealth of information about palaeoclimate, palaeoecology, phytogeography and evolution. Without them our knowledge about the arborescent plants of the past would have remained largely incomplete. They are of great economic importance as a source of energy since they form the major component of our coal and lignite.

XYLEM or wood is a complex tissue made up of more than one type of cells working together as a unit. It results from the activity of a special meristem, the vascular cambium, and constitutes the bulk of woody gymnospermous or angiospermous tree trunks. The xylem as a whole is meant to conduct water and mineral salts upwards from the root to the leaves and to give mechanical strength to the plant body. Xylem consists of (i) tracheids, (ii) vessels or tracheae, (iii) wood fibres, and (iv) wood parenchyma. The first two are called 'tracheary elements' and are concerned with conduction. They are non-living at maturity. Wood fibres mainly provide mechanical strength to the plant body and are usually dead cells. However, fibres with living protoplast and nuclei have been found to occur in many woody plants[1]. All the three xylem components are lignified and thick walled. Wood parenchyma is associated with storage of starch, oils and many other ergastic substances and consists of living cells. Sometimes parenchyma cells develop secondary walls and become lignified[1,2]. Wood is a fairly compact and hard material which resists decay and for this reason it often gets fossilized and is found most frequently in fossil records. The study of the anatomy of xylem or wood is called xylotomy.

Fossilization of wood

Wood may become fossilized in various ways though the main process is always by burial. The burial may be violent as happens in the case of volcanic eruption by lava flows or by extensive floods but usually it is gradual and gentle as may be observed in the peat bogs, lakes, rivers and along the sea shores. The burial material such as sand or mud slowly consolidates into rock. The wood under preservation often gets flattened forming coaly fossils called compressions. Due to flattening, the original structure of the wood in compression is usually crushed and is obscured. However, such flattening is generally prevented by the process of fossilization known as petrifaction and permineralization[3] in which the wood becomes partly or even completely replaced by minerals, usually by silica, in the form of opal, chalcedony or agate but sometimes by iron pyrites or calcium carbonate[3–6]. The wood is thus changed into stony fossils and unlike in compressions, the original shape and internal microscopic structures of such woods are well preserved. Petrified woods allow sectioning and examination of the tissue under microscope. Many petrified woods such as those of Deccan intertrappeans are preserved in this way. Internal structure may also be preserved perfectly when wood is fossilized as a charcoal-like material called 'fusain' which was probably formed by charring of trees due to forest fires. Petrifactions are the most frequently occurring type of fossil woods (Figure 1 *b*, *d*). Their occurrence in the arid and treeless landscape of Kutch and Rajasthan is of particular significance as a striking reminder of dense forests which must have flourished there millions of years ago. Sometimes we get moulds or casts of fossil woods. They are in a way the negatives of the plant material. The mould faithfully reproduces the surface features of the stem or wood, such as the design of bark, knots, wound and leaf bases. However, if other sediments get into the cavity of the mould and solidify, a cast or a possible replica of the original material is formed. Moulds and casts depict only the external form of fossil wood (Figure 1 *c*). Bark is very rarely found intact in fossil woods. It is the first casualty in transportation and early degradation of wood. Presence of bark in fossil woods provides an evidence of quick burial. It also indicates that the fossil has not drifted too far from its place of origin and hence is of considerable significance in determining the provenance of fossil woods. The tree trunks and branches have been recovered from the high tide water marks of sea in the Piram island, off the coast of Bhavnagar in Gujarat. It seems that as these woods drifted into the ancient sea, they were attacked by wood eating animals such as marine wood borer, *Teredo*, a bivalve mollusc, before fossilization. The borings made by penetration of these worms are often seen preserved in the fossilized woods (Figure 1 *b*). These woods were often fossilized as petrifactions with iron pyrites. A large number of

(×15).

woods have also been preserved and described in the form of compressions from the lignite mines of India such as Rajpardi in Gujarat[7], Neyveli in Tamil Nadu and from the Tertiary sediments of Kerala and Maharashtra[8] (Figure 1 *a*) besides Andaman–Nicobar Islands[9]. Such type of woods have also been reported from the Plio-Pleistocene sediments of the Karewa lakes of Kashmir[10]. Sometimes calcified woods have also been found at different places. Pleistocene woods are also found sometimes in the inland lakes. Thus all kinds of fossil woods have been reported from India.

Identification of fossil woods

The identification of fossil woods requires detailed observation of their internal microscopic structures. Sometimes anatomical details are well preserved, particularly in cherty material. To study fossil woods, thin sections are cut in various planes such as transverse, tangential and radial, which help to build up the three-dimensional picture of the fossils as is the case for the study of extant woods. These sections are then ground, polished and examined under microscope. This method was first applied to petrified woods as early as in 1831 by Henry Witham and was followed by later palaeobotanists[11]. Anatomical features such as growth rings, tracheids, vessels, parenchyma, rays, fibres, resin canals and various kinds of minute pits, etc. are then examined (Figures 1 *g*, 2 *b–m*). Based on these characters, fossil woods can be identified and classified under various taxa and groups. Sometimes minute microscopic details are not preserved or remain obscure which makes it difficult to identify such woods to generic or specific levels.

Indian fossil woods

Oldest fossil woods from India come from the Palaeozoic sediments. A large number of fossil woods are known from the Lower Gondwana (Permian) formations of India. The vast forests of the Permian which covered much of Indian landmass during 245 m.y. –280 m.y. are represented in our coal seams by wood compressions and also by well-preserved petrifactions. All the known Indian Palaeozoic woods belong to Gymnosperms. The compression form is represented by *Vertebraria* Royle, referable to *Glossopteris*[12,13] irrespective of the fact of its being a stem or a root. The petrified woods have been described under various artificial genera, a comprehensive list of which has been given by Prasad[14]. These woods occur primarily in the Lower Barakar and Upper Raniganj and equivalent Kamthi formations of the Lower Gondwana. Surprisingly no wood has been reported from the Talchir, Karharbari and Kulti (Barren Measures) formations.

*Raniganj Formation/ *Kamthi Formation
Kulti Formation (Barren Measures)
*Barakar Formation
Karharbari Formation
Talchir Formation

(General sequence of Lower Gondwana formations of India, those containing fossil woods are marked by an asterisk).

Most of these woods have been reported from West Bengal (Raniganj Coalfield), Bihar (Jharia Coalfield) and Maharashtra (Kamthi Formation). A few records are also known from Andhra Pradesh, Madhya Pradesh and Uttar Pradesh (Singrauli Coalfield, Mirzapur District). Most of the fossils consist only of secondary wood but some of them possess homo- to heterocellular pith with sclerotic or secretory cells and endarch primary xylem. In these Lower Gondwana woods the secondary xylem is pycnoxylic, more or less uniform and mostly possesses araucarioid pittings but sometimes a mixture of araucarioid and abietoid pits along with taxinean spirals. The presence of well-defined growth rings in these woods indicates some climatic fluctuations. The xylem rays are homogeneous, generally 1–2 seriate, the cross field pits may be one to many, circular, bordered, araucarioid and taxodioid. These woods have often been found in coal-bearing beds in association with impressions of representatives of the *Glossopteris* flora. Although these woods are undoubtedly gymnospermous, their further affinities cannot be ascertained in the absence of any other supporting evidence. They could represent any of the orders like Glossopteridales, Cordaitales. Taxales and Ginkgoales. Gymnosperms were the most dominant group of plants in the Permian of India as has also been revealed by a large number of foliar taxa[15]. They continued their dominance throughout Mesozoic and Early Cretaceous. Birbal Sahni enhanced the significance of fossil woods by naming a new and enigmatic group of gymnosperms as Pentoxyleae after the characteristic wood genus *Pentoxylon* Srivastava (Figure 2 *a*, *b*) reported from the Rajmahal Hills of India[16], then considered to be Jurassic in age. The group Pentoxyleae has been accorded the status of an order Pentoxylales by later palaeobotanists. The age of the Rajmahal sediments has since been revised as Lower Cretaceous. The woods of Pentoxylales are remarkable in having poly 'steles' or many vascular 'bundles'[17]. *Pentoxylon sahnii* frequently had five steles. The name of the genus and the group was derived from this feature. Five was the commonest number of steles though the number varied. The secondary wood was compact and markedly eccentric with a much greater development towards the centre of stem with distinct growth rings (Figure 2 *b*). Although polystelic features of the stems show resemblance with Palaeozoic medullosan

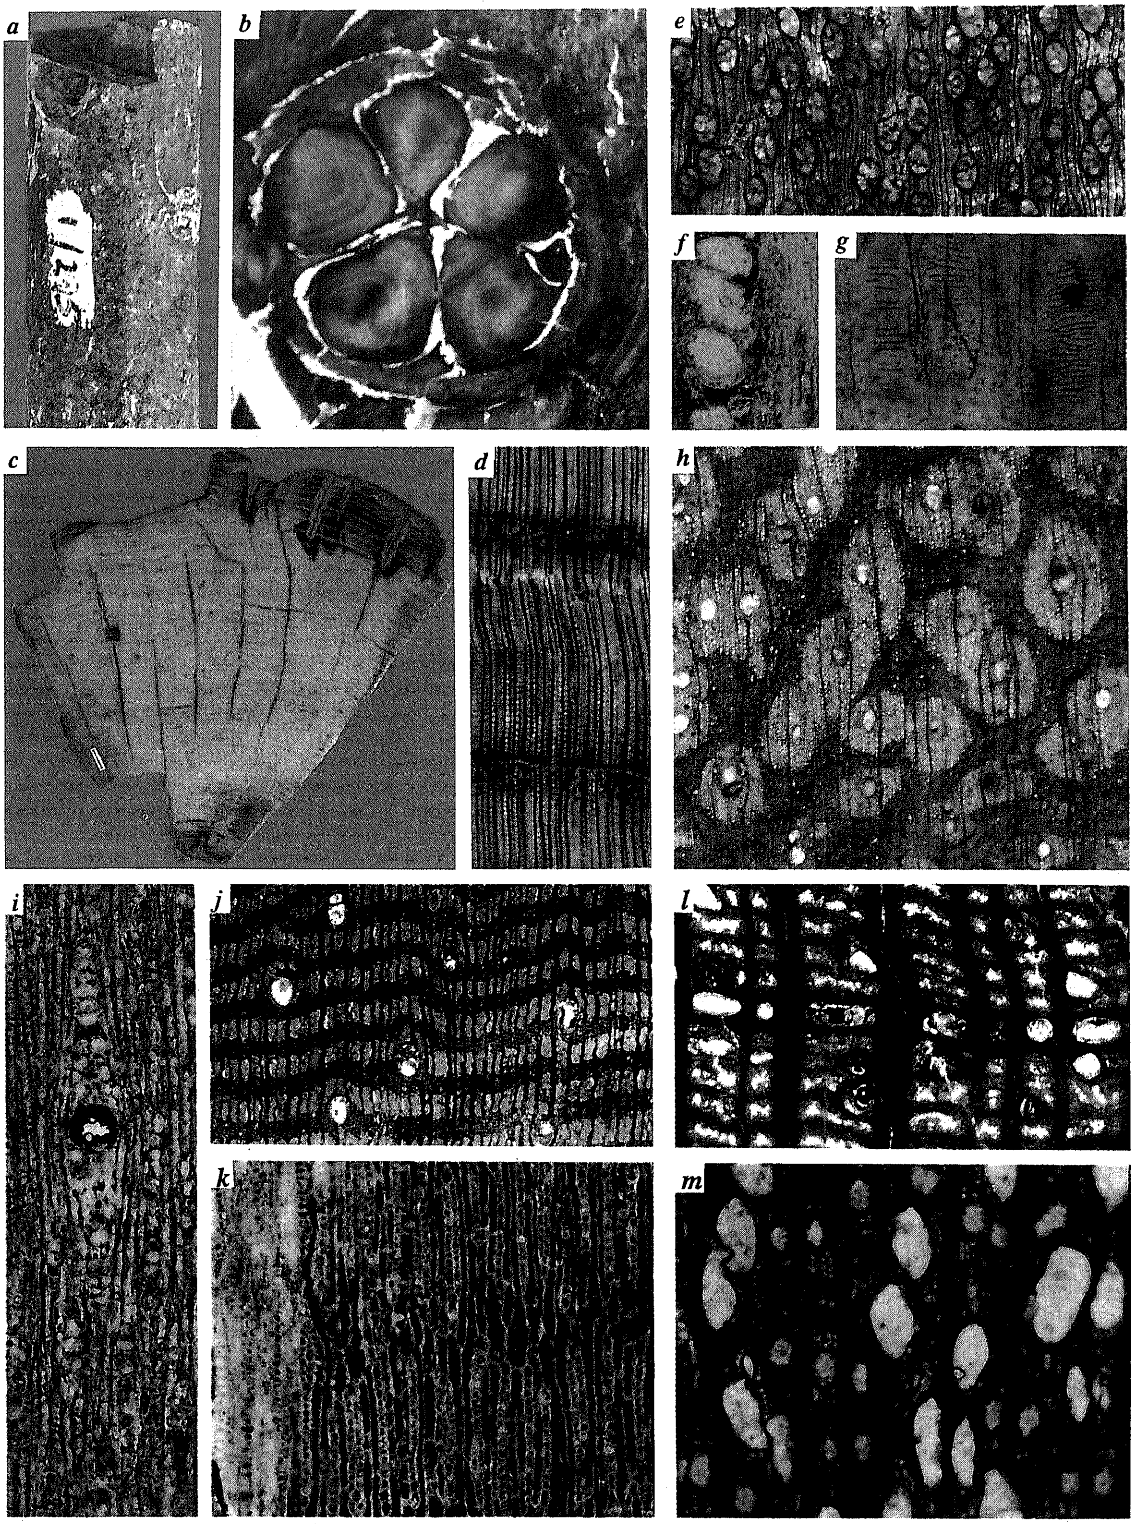

Figure 2 ***a–m***. ***a***, A specimen of *Pentoxylon sahnii* (× 2); ***b***, Transverse section of *Pentoxylon sahnii* showing polysteles, eccentric pycnoxylic wood and growth rings (× 10); ***c***, Transverse section of *Sahnioxylon rajmahalense* showing distinct growth rings (× < 1/2); ***d***, Transverse section of *Sahnioxylon rajmahalense* showing size difference in growth rings of early and late wood (× 15); ***e***, Transverse section of a fossil wood showing highly tylosed solitary vessels (× 20); ***f***, Tyloses in a vessel as seen in longitudinal section of a fossil wood (× 70); ***g***, Radial longitudinal section of *Hydnocarpoxylon indicum* Bande and Khatri showing scalariform perforations in the vessels (×100); ***h***, Transverse section of a fossil wood of *Isoberlinia* (an African genus) from Kachchh showing abundant paratracheal parenchyma (× 20); ***i***, Longitudinal section of a fossil wood of *Mangifera (Mangiferoxylon scleroticum* Awasthi) showing radial gum canal in the rays (× 70); ***j***, Transverse section of a fossil wood of *Millettioxylon indicum* Awasthi showing banded type of parenchyma (× 20); ***k***, Longitudinal section of *Millettioxylon indicum* Awasthi showing storied arrangement of xylem rays (× 70); ***l***, Transverse section of *Sterculinium kalagarhense* Guleria showing banded parenchyma and traumatic gum canals forming a row (× 20); ***m***, Transverse section of *Dipterocarpoxylon pondicherriense* Awasthi from Kachchh showing large solitary vessels and small axial gum canals (× 15).

ferns, they differ in having pycnoxylic wood as seen in gymnosperms.

The earliest records of flowering trees in India, in the form of a large number of petrified woods, have been reported from the Deccan Intertrappean sediments of Late Cretaceous–Early Tertiary of Central India of about 65 m.y. age. They represent varied dicot genera, even woody lianas, *e.g.*, *Aristolochioxylon*, and a number of palms[18] which are the characteristic components of any moist tropical forest. Similarly a large number of modern genera are represented by their fossil woods in the Neogene sediments[8,19]. Widespread occurrence of fossil woods of Dipterocarpaceae, the dominance of leguminous woods along with wood remains of Sapotaceae, Ebenaceae and Rosaceae help to demarcate the Neogene flora of India from the Palaeogene. Gymnosperms were rare during the Tertiary. With the advent of angiosperms they obviously declined fast and became a moribund group. They are represented by the rare occurrence of woods of *Araucarioxylon* and *Podocarpoxylon*, the two typical southern gymnosperm genera until the invasion of northern conifers in India such as *Abies*, *Cupressus* and *Pinus*, whose wood remains have been found in the Pliocene–Pleistocene deposits of Kashmir[10]. Thus the fossil woods are an important source of information in tracing the antiquity of extant arborescent plants.

Discussion

As stated earlier, wood provides mechanical strength to the plant body and conducts water and mineral salts from roots to leaves. These functions are vital to terrestrial life. Thus the development of woody or vascular plants was a critical factor in the initial conquest of land by plants around 410 m.y. ago (Ludlovian) during the Upper Silurian period. The evidence for this was provided by Obrhel[20] by his discovery of *Cooksonia* (*C. hemispherica*), an extremely simple plant consisting of small, naked or leafless, dichotomizing axes with slender cetrarch protosteles bearing terminal sporangia, from the Middle Ludlovian deposits of Bohemia, belonging to sub-division Rhyniophytina[21,22]. *Cooksonia* is thus considered to represent geologically the oldest vascular plant known to date. The vascular system consists of slender strand of annular tracheids[23]. The middle Devonian (Givetian, about 370 m.y. ago) period heralded the initiation of the cambial activity leading to the secondary growth (*Schizopodium*). Thus the anatomical studies of fossil woods has enabled us to understand how the pioneering land plants evolved from the earliest seaweed-like forms to some of the first large trees such as *Archaeopteris* and *Callixylon*, the pro-Gymnosperms which first appeared in the Middle Devonian about 380 m.y. ago[24]. Likewise polysteleic nature of *Pentoxylon* and related stems along with pycnoxylic wood have provided some kind of connecting link between the ferns (Medullosan type) and the gymnosperms.

The study of fossil woods has provided substantial data about palaeoclimate, palaeoecology, palaeogeography, phytogeography and evolutionary characters[8,18,19,25–34].

Analysis of growth rings in fossil woods provides information about palaeoclimate[35,36]. Depending on changes in radial cell diameter within the growth ring and the variation in the ring width, it is possible to extrapolate climate information. This study of tree rings to reconstruct past and present climate is called 'dendroclimatology' which is a subfield of 'dendrochronology'[37]. This kind of study has lately been seriously undertaken in our country[38,40]. Dendrochronological research could contribute to a better understanding of the dynamics of monsoon[41]. Growth rings are normally distinct and well defined in trees of temperate regions with pronounced seasonal changes. Accordingly, Permian to Early Cretaceous Indian woods show well developed and distinct growth rings (Figure 2 *b–d*) on account of palaeolatitudinal position of Indian Plate in cooler region at that time[42,43]. Growth rings are usually not well marked and indistinct in the woods of tropical trees (Figure 2 *e*, *j*, *l*) with a few exceptions like *Tectona grandis*, etc.[44–46].

The Late Cretaceous–Early Tertiary Deccan Intertrappean flora is mainly represented by fossil woods whose study has provided the bulk of information about the composition of this flora. A large number of its woody dicot genera such as *Artocarpus*, *Barringtonia*, *Canarium*, *Dracontomelum*, *Drypetes*, *Garcinia*, *Homalium*, *Lophopetalum*, *Polyalthia*, *Sonneratia* and *Syzygium* indicate that at that time tropical humid conditions prevailed over the Indian peninsula[47]. Somewhat similar climatic conditions extended into the later half of the Tertiary as is revealed by a large number of woods of the dipterocarpaceous taxa (e.g., *Anisoptera*, *Dipterocarpus*, *Dryobalanops*, *Hopea*, *Shorea*, etc.) along with those of *Calophyllum*, *Gluta*, *Cynometra* and *Afzelia-Intsia*. In addition to these, the occurrence of *Bauhinia*, *Cassia*, *Cordia*, *Mangifera*, *Ormosia*, *Sterculia*, *Terminalia*, etc., ranging from semi-evergreen to deciduous woody taxa in the Late Tertiary, indicates a gradual decrease in rainfall and evolution of drier conditions. Palaeogeographically the occurrence of fossil woods of *Sonneratia* in the Tertiary of central and western India and *Heritiera* in eastern India indicates the existence of coastal conditions far inland in the past than at present. Likewise fossil woods of *Lagerstroemia*, *Dracontomelum*, *Drypetes*, *Syzygium*, *Terminalia arjuna* and *Barringtonia* indicate the presence of water channels and damp or swampy conditions.

The occurrence of certain South American, African and Australian woods such as *Simarouba*=*Quassia*[48,49], *Hyphaene*[50] and *Eucalyptus*[51] in the Deccan Intertrappean (Late Cretaceous) sediments of Central India indicates the proximity of South America, Africa and Australia to India at that time. The occurrence of these taxa in India probably represents angiospermic remnants of the Gondwanaland flora. Similarly the presence of certain typical Malayan elements, largely represented by the woods of dipterocarpaceous genera[25] (Figure 2 *g*) and African taxa like *Isoberlinia* (Figure 2 *h*), *Entandrophragma*, etc.[52,53] in the Upper Tertiary sediments of India and their complete absence in the Deccan Intertrappean sediments indicate the invasion of such genera from the east and west respectively, after the establishment of land connections with India by early Miocene through Indonesia and Myanmar on one hand and via Ethiopia and Arabia on the other. Likewise the complete absence of woods or any other megafossils of northern conifers such as Pinaceae in the Miocene sediments of the Indian subcontinent indicates that these conifers entered into India after the uplift of the Himalayas at the end of Miocene when the conditions became cooler and conducive to their growth. The occurrence of a fossil wood of *Prunus* in the Miocene sediments of Ladakh[54] at a height of 4581 m indicates the uplift of the Himalayas by about 2445 m since then as *Prunus* does not grow above 2140 m at present. Based on detailed analysis of Indian fossil woods ranging from Deccan Intertrappeans to Neogene in age, Bande and Prakash[27] have been able to trace the evolutionary trends in the secondary xylem of dicot woods. Features like wide apotracheal parenchyma bands and storied structures of various elements such as rays, wood fibres and parenchyma are more advanced and hence they are found frequently in the younger Neogene woods in contrast to older Deccan Intertrappean woods (Figure 2 *j–l*). Similarly vessel members with scalariform perforations are more common in Deccan Intertrappean woods than in the younger Neogene woods since it is considered to be a primitive feature (Figure 2 *g*). Normal axial gum canals are present in the Neogene woods (Figure 2 *m*) whereas they are absent in the Pre-Neogene Indian woods.

Fossil woods are of great economic importance when they occur in large quantities as in the case of lignite and coal mines. Neyveli lignite is composed of large number of fossil woods and a number of carbonized woods have also been collected from the Rajpardi lignite mine of Gujarat[7,8] (Figure 1 *a*). Similarly Gondwana coals also consist of woody material[55] besides other vegetal remains. Such large deposits of lignites and coals are our major source of energy. In addition, petrified wood logs have been used by villagers as pillars and support bases for making their houses (Figure 1 *f*) in the north-east India and for marking the boundaries of fields in almost all other areas near fossil localities. They have occasionally been used as curios and for decorative purposes (Figure 1 *e*) after cutting and polishing.

The so-called fossil wood forests or parks with a large number of tree trunks as at Tiruvakarrai in Tamil Nadu (Figure 1 *d*), Mandla in Madhya Pradesh and Akal fossil park near Jaisalmer in Rajasthan, act as repositories of arborescent fossil plants and remind us of our luxuriant forests during the past.

Adult crowding effects on longevity in *Drosophila melanogaster*: Increase in age-independent mortality

Amitabh Joshi* **and Laurence D. Mueller**

Department of Ecology and Evolutionary Biology, University of California, Irvine, CA 92717, USA
*Present address: Animal Behaviour Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore 560 064, India

The manipulation of longevity through environmental treatments has provided many insights into the physiological processes affecting life-span. Here, we report the reduction of longevity in adult *Drosophila melanogaster* after three days of moderate adult crowding. Crowding is shown to reduce life-span through increased age-independent mortality rather than through altering the rate of ageing. Preliminary evidence also suggests that increased age-independent mortality after crowding may result from a reduction in stored energy reserves. The results also suggest that populations of *D. melanogaster* routinely maintained at high-adult densities may be relatively less susceptible to the detrimental effects of crowding on longevity.

THE study of ageing has long been approached at two different levels of biological organization: at the individual and sub-individual level by gerontologists, and at the populational level by demographers. In the past one-and-a-half decades, evolutionary biologists have tried to unite these divergent approaches by trying to understand how and why ageing evolves, an approach that combines demography, population genetics and physiology[1-3]. From this evolutionary viewpoint on ageing, longevity (or life-span) is seen as but one among a multitude of life-history traits, all interrelated as a consequence of shared underlying physiological constraints[2-10].

Genetic and environmental manipulation of longevity

Many studies on ageing in the past several years have focused upon genetic and environmental manipulations of life-span[2,3]. For example, increased life-span has successfully been selected for in *Drosophila melanogaster* by several workers independently[1,11-13]. Similarly, environmental manipulations such as dietary restriction[6], restricted mating[14-16], and the addition of urea to the food medium[17] have all been observed to enhance longevity in *D. melanogaster*. Similar effects of many environmental treatments on longevity have also been observed in a variety of other invertebrate[7,18-21] and vertebrate[22-24] species. Moreover, investigation of the physiological mechanisms underlying observed genetic and environmental effects on longevity has provided useful insights into the nature of the constraints placed by correlations among life-history characters upon the attainment of increased life-span under a given set of conditions[2,5,25-27].

Estimating the rate of ageing

The demographic perspective on ageing suggests another level at which the nature of the effect of various factors on life-span can be assessed, by focusing on rates of ageing, rather than on changes in life-history traits correlated with longevity. In recent years, several studies have focused on 'rates of ageing' as reflected by the α parameter of the Gompertz equation[28] that models age-specific mortality as an exponentially increasing function of age[17,24,29-32]. According to the Gompertz equation, the mortality rate at age x, $\mu(x)$, is given by

$$\mu(x) = Ae^{\alpha x},$$

where the two parameters, A and α, represent the age-independent mortality rate and the rate of increase in mortality rate with age, respectively: this latter parameter, α, is considered to represent the rate of ageing[2,18,29-32]. Results of some studies on *Drosophila*[17,32] strongly suggest that environmental factors affecting longevity tend to do so through their effect on the age-independent Gompertz parameter (A), whereas genetically induced changes in longevity tend to involve changes in the Gompertz 'rate of ageing' (α). There is also some evidence that, in the bruchid beetle *Callosobruchus maculatus*, mating *per se* may affect the Gompertz 'rate of ageing', whereas egg-production affects the age-independent Gompertz parameter[18].

Adult density and longevity

Adult density is an environmental factor that is known to adversely impact a variety of fitness correlates in diverse species[33–39]. In *Drosophila*, adult crowding over a period of many days has been shown to significantly reduce longevity[33,37]. In the present study, we used a set of 15 populations of *D. melanogaster*, that had been subjected to life-stage-specific density-dependent natural selection in the laboratory, to seek answers to the following questions: (i) Can brief episodes of moderate levels of adult crowding significantly reduce longevity? (ii) Is the effect, if any, of adult crowding on longevity mediated through changes in the age-independent or age-dependent parameters of the Gompertz equation, or both? (iii) Are populations regularly maintained at high adult densities better able to withstand the deleterious effects, if any, of adult crowding on longevity?

Methodology

Experimental populations

This study used three sets of five replicate populations of *D. melanogaster* that had each been subjected to differing levels of larval or adult density for over 50 generations[40]. All populations were maintained on banana-molasses food at 25°C, continuous light, and had a generation time of about 3 weeks. Population sizes of each generation were of the order of 2000–4000 breeding adults. The five populations crowded as larvae ($CU_1 \ldots CU_5$) were reared at densities of 1000 or more larvae per 6 dram vial (2.2 cm d × 8.4 cm h). Eclosing adults were collected daily from these vials, and kept at a low density of about 60–80 adults per 8 dram vial (2.4 cm d × 9.5 cm h). The five uncrowded populations ($UU_1 \ldots UU_5$) were reared at low larval densities of 60–80 larvae per 8 dram vial; eclosing adults were subjected to the same density as the CU populations. The five populations crowded as adults ($UC_1 \ldots UC_5$) were reared at low larval densities of 60–80 larvae per 8 dram vial; eclosed adults were collected from these vials on the 13th day after egg-laying and kept in 8 dram vials at densities of about 160–200 adults per vial. The three sets of populations, thus, differed in the degree of larval or adult crowding to which they were exposed, with the UU populations acting as controls to both the UC and CU populations. Prior to initiating a new generation, all the eclosed adults from a population were dumped into a plexiglass cage (25.5 × 20 × 14.4 cm^3) and supplied with liberal amounts of live yeast paste for 2 days before egg collection. All three sets of populations were derived from the five B populations of Rose[1], each B population being used as the progenitor of one CU, one UC, and one UU population. Consequently, CU, UC and UU populations bearing the same numerical subscript are more closely related to each other, as compared to other populations subjected to the same density regime.

Collection of adult flies for longevity assay

Prior to initiating the longevity assay described below, all test populations were passed through one complete generation of identical rearing conditions, to eliminate any differences among selected lines due to environ-

Table 1. ANOVA for longevity of UU, UC and CU flies after three days of crowded (150 flies/vial) or uncrowded (8 flies/vial) conditioning (Cond). Longevity was assayed on flies kept in groups of 4 males and 4 females per vial. Significant fixed main effects and interactions are indicated in bold type (Blk, block, Sel, selection, Cond, conditioning treatment; parentheses are used to denote nested effects)

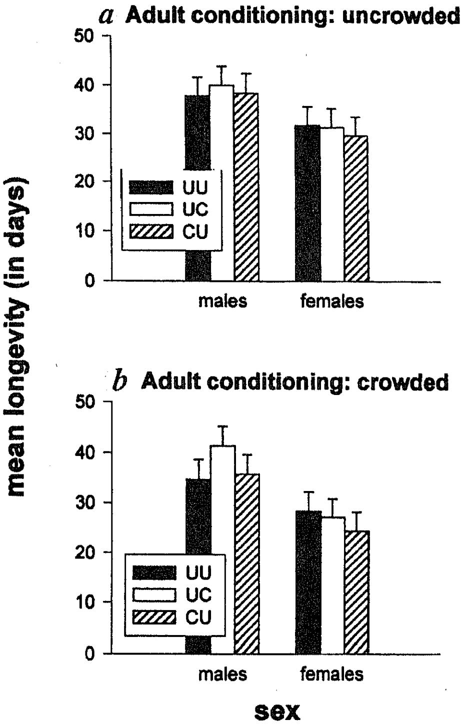

Figure 1. Mean longevity of flies after three days of uncrowded (*a*) or crowded (*b*) conditioning as adults. The error bars depict 95% confidence intervals about the mean of the five replicate populations of each selection regime, and were calculated using least squares estimates of the standard errors of cell means in the randomized block ANOVA.

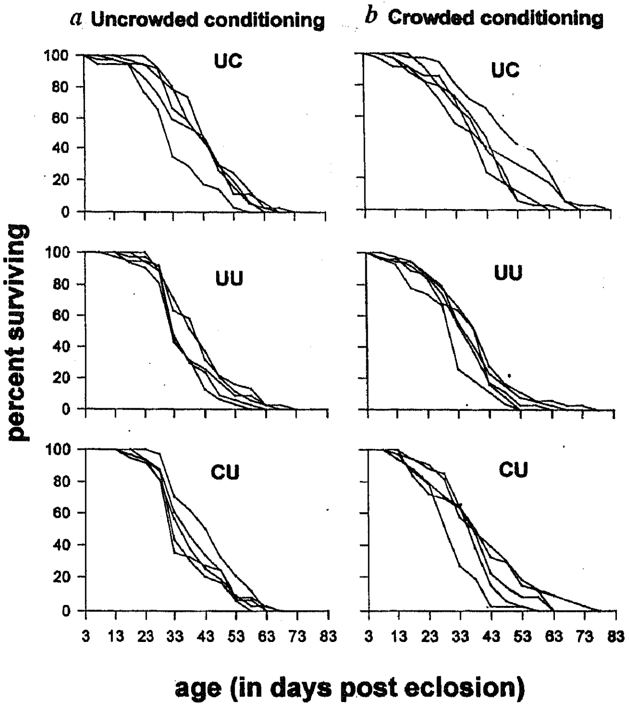

Figure 2. Per cent survival to various ages of adult males from each of the 5 replicate UU, UC and CU populations, after three days of high (150 flies/vial) or low (8 flies/vial) density conditioning.

mental or maternal effects. Eggs were collected from the adults of each stock population and placed in 8 dram vials at low densities of 60–80 eggs per vial. Eclosing adults from these vials were then collected into cages; eggs laid by these adults were collected and transferred into 8 dram vials at low densities of 60–80 eggs per vial. Adult flies eclosing in these vials were collected one day after eclosion, and subjected to one of the two conditioning treatments: crowded (75 males and 75 females per vial) or uncrowded (4 males and 4 females per vial). All conditioning vials contained exactly 5 ml of food medium. For each population, 7 vials were set up at high density and 15 at low density, adding up to a total of 330 conditioning vials (3 selection regimes × 5 replicate populations × (7 vials at high density, 15 vials at low density). The flies remained in these vials for 3 days, after which they were used for setting up the longevity assay described below.

Longevity assay

After 3-day conditioning period, flies were placed into vials with about 3 ml of food medium at a density of 4 males and 4 females per vial; 10 such vials were set up for each population × conditioning combination. Thus, a total of 2400 flies were assayed for longevity. The flies were transferred to fresh food vials every third day until all flies had died. All vials were checked daily for deaths. Dead flies in a vial were not replaced over the course of the assay. Life-span was measured as the time, in days, from the start of the conditioning to the day of death. The longevities reported here are, consequently, the conditional longevities of flies that survived the 3 days of conditioning.

Statistical analysis

The longevity data were subjected to an analysis of variance (ANOVA) using the procedure GLM of SAS for Windows version 6.08. Due to the pattern of relatedness among the CU, UC, and UU populations (CU_i ,UC_i ,and UU_i are more closely related to each other than either of them is to other populations with which they share the same selection regime, $i = 1..5$), sets of CU, UC and UU populations, matched by subscripted indices, were treated as random blocks in the analyses. Selection-regime and conditioning density were treated as fixed effects crossed within each block (our primary interest was in these fixed effects; block in this experiment confounds ancestry and handling effects and, thus, although we are interested in accounting for this variation by treating block as a factor, we do not try to interpret any significant random effects). Because the measurement of longevity was done on individual flies in each vial, the ANOVA model included vial as a random effect nested within the block × selection × conditioning interaction. Sex was treated as a fixed factor crossed with all the rest.

From the data on longevity, we also estimated the age-independent (A) and age-dependent (α) parameters of the Gompertz equation that models the age-dependence of mortality rates[28], using a maximum likelihood method utilizing untransformed survival data[31]. The estimates of A and α from each population ´ conditioning combination were then used as data for analyses of variance, treating selection-regime, conditioning and sex as fixed factors crossed within the 5 replicate blocks. In similar previous experiments we have tested the goodness of fit of the Gompertz equation to data on mortality collected from males and females of over 20 populations of *D. melanogaster* related to the populations used in this study under various environmental conditions and the fit has always been excellent with R^2 values consistently being above 90% (refs 17,31).

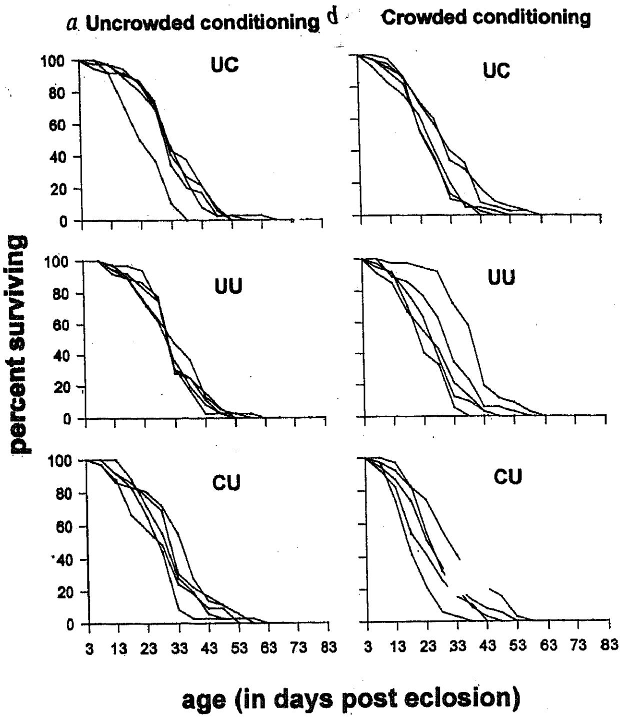

Figure 3. Per cent survival to various ages of adult females from each of the 5 replicate UU, UC and CU populations, after three days of high (150 flies/vial) or low (8 flies/vial) density conditioning.

Effect of adult crowding on longevity

The ANOVA results for longevity after 3 days of adult conditioning showed significant fixed effects of sex and conditioning density; selection regime did not have a significant effect (Table 1). In general, longevity decreased with increasing density of conditioning (an average reduction due to crowding of 2.75 days), and, as expected for *Drosophila*, males outlived females by an average of 9.2 days (Figure 1). Females were seemingly affected by crowding to a degree greater than the males: crowding reduced the longevity of females by an average of 4.2 days whereas in the case of males, the reduction was only 1.3 days.

Unfortunately, too much cannot be made of these differences because the early death of large numbers of females in the crowded treatment would tend to increase life-span in males due to reduced courtship and mating, thus counteracting to some degree the detrimental effect of the crowding treatment experienced earlier. Moreover, the degree and duration of crowding experienced by the populations in this study was moderate (mean mortality in our populations during the 3 days of crowded conditioning varied from less than 1% to 11.6%, whereas more severe crowding for 5 days in the same populations can yield mortality up to 90% (ref. 41). We were, therefore, more interested in broad patterns of mortality effects than in the specific magnitudes of the effects. Overall, there did not appear to be major differences in the pattern of effects of adult crowding on either mean longevity in the UU, UC and CU populations (Figure 1), or on the survivorship curves of males and females from these three types of populations (Figures 2, 3). The only significant difference among selection lines was that the mean longevity of UC males from the crowded conditioning treatment was greater than that of both CU ($P = 0.02$) and UU ($P = 0.01$) males. At a qualitative level, nevertheless, the per cent decline in mean longevity due to adult crowding was the greatest in the CU, and the least in the UC populations.

The ANOVA results for the age-independent (A) and age-dependent (α) mortality parameters of the Gompertz equation indicated that the crowded conditioning treatment lowered longevity through an increase in A. Of the fixed factors in the ANOVA model, sex, conditioning, and the selection regime × sex interaction were seen to have significant effects on the estimates of A, while only sex had a significant effect on estimates of α (Table 2). The reduced longevity of females, as compared to males, is well known in *Drosophila*[7,31], our re-

Table 2. Estimates of the age-independent (A) and age-dependent (α) mortality parameters of the Gompertz equation. The entries are the means (± 95 % confidence intervals) of the five replicate populations in each selection regime × conditioning combination. The only significant effects in the ANOVA were those of sex, conditioning, and selection regime × sex on estimates of A, and of sex on estimates of α.

sults show that this is due to both greater age-independent mortality (mean A in females was 0.0043, a 53% increase over the mean in males, 0.0028) and a more rapid rate of ageing (mean α in females was 0.1016, a 23% increase over the mean in males, 0.0826). The mean value of A in populations subjected to the crowded treatment was 0.0042, a 44% increase over the mean in the uncrowded treatment, 0.0029. The significant selection regime × sex interaction for estimates of A arose from the fact that means of selection regimes for the crowded and uncrowded treatments did not differ significantly in the case of males, but did so in the case of females (Table 2).

Conclusions

The results of the present study are consistent with the findings of previous studies that adult crowding reduces longevity in *Drosophila*[33,37]. Moreover, our results indicate that even brief periods of relatively moderate crowding can have a lasting effect on subsequent longevity (Table 1, Figure 1). Interestingly, it is also clear that, like other environmental factors affecting longevity in *Drosophila*[17,32], adult crowding affects longevity by altering the age-independent mortality rate rather than the rate of ageing *per se* (Table 2). The commonly observed difference in longevity between males and females in *Drosophila* is shown to be due to increased age-independent mortality, as well as an increased rate of ageing in females (Table 2).

Although selection regime did not have a statistically significant effect on the extent to which crowding reduced longevity (Table 1), our results suggest that the UC populations may, in fact, have a reduced sensitivity to adult crowding, as a result of having been subjected to high adult densities for over 50 generations (Figure 1). Possibly, a more severe bout of crowding would lead to differences among the selected lines that would be picked up as being statistically significant. This interpretation is supported by the finding that the UC populations are significantly less sensitive to adult crowding effects on fecundity and mortality during crowding than either the CU or the UU populations[41].

One very consistent finding of previous studies on environmental and genetic modifications of longevity has been the existence of a ubiquitous trade-off between female fecundity and longevity[2,3,17]. This trade-off has been interpreted in light of the so-called Y-model of resource allocation[6,10,42]. In this view, reproduction and survival are envisioned as being alternative candidates for the allocation of energy reserves by organisms, such that, all other things being equal, increased reproductive output comes at the expense of survival, and *vice versa.* A series of studies on *Drosophila* populations closely related to our CU, UC and UU lines, suggest that fecundity and longevity in these populations are, in fact, linked in this manner, based upon their common dependency on lipid as a resource[4,6,27,43]. Similarly, most environmental factors increasing or decreasing longevity in many species have been shown to do so by respectively reducing or enhancing fecundity. Since the reduction of female fecundity by adult crowding is a well-documented phenomenon in *Drosophila*[44], one might naively expect that adult crowding would, therefore, enhance longevity.

In fact, the observed reduction in longevity, by levels of adult crowding that are known to also depress fecundity in the UU, UC and CU populations[41], strongly suggests that the negative impact of adult crowding on longevity in our experiment is mediated by a reduction in the overall levels of stored energy reserves in the flies subjected to the crowded conditioning treatment. In this context, it is interesting to note that even 24 hours of adult crowding reduced subsequent starvation resistance in the B populations from which our experimental populations were derived[37]. Given the close relationship between starvation resistance and lipid content in *Drosophila*[4,6,8], this suggests that brief episodes of adult crowding may significantly deplete lipid reserves. However, there are also indications that reserves of glycogen, rather than lipid, may be more severely affected by adult crowding[37]. Evidently, further studies of the physiological consequences of adult crowding are needed to obtain a clearer picture of how the effects of crowding on adult fitness components are mediated by the underlying architecture of inter-related metabolic pathways.

Neural network modelling of human electroencephalogram patterns

D. Mukesh and R. Y. Nadkar

ICI India R & T Centre, PO Box 155, Thane–Belapur Road,
Thane 400 601, India

A general regression neural network model with different processing elements (PE) fits the observed electroencephalogram signals (EEG) of the human brain during awake, sleep and rapid eye movement (REM) stages. The number of PEs required for simulation could be an indication of the complexity of the EEG pattern. About 6.5 times more PEs are required to simulate the signal during alert eyes open (β waves) than alert eyes closed (α waves) stage. Also, half the number of PEs are required to simulate sleep stage 4 when compared to simulating sleep stage 2. REM sleep requires more number of PEs to simulate than sleep stage 4. PEs required to simulate short duration 'petit mal' epileptic seizure less than those required to simulate β waves, but more than those required to simulate REM state. In most cases a correlation exists between the number of PEs and the fractal dimension.

THE neuron is the fundamental cellular unit of the nervous system and, especially the human brain. The central nervous system is a neural network of about 10^{11} neurons, all of them interconnected in the form of a dense matrix. The neocortex is under the influence of external stimuli as well as input from subcortical areas. The axon or the output path of a neuron splits up and connects to dendrites or input paths of other neurons through a junction known as a synapse. The electrical activity of the brain is routinely measured from the scalp and analysed for abnormalities. It is used in the search for sleep disorders.

Electroencephalogram (EEG) is related to the firing pattern of the neurons in the neighbourhood of the cerebral cortex. Cells continuously receive pulses, especially at dendrites, from other neighbouring neurons. The pulses are transmitted at synapses. Certain incoming pulses generate excitatory waves, while others generate inhibitory waves of electric current in the recipients. These dendritic currents are fed through the cell body to a region at the start of the axon. These currents enter the extracellular space after crossing the cell membrane. The cell calculates the overall strength of the currents, which is indicated by changes in voltage across the membrane, by adding all the excitatory and subtracting all the inhibitory currents. If the sum is above a threshold value then the neuron fires (i.e. an output from the neuron is generated). Although the activity of real neurons is very complex what is described above is an oversimplification of the process of synaptic integration.

The mechanism producing each EEG tracing sums up the currents initiated at the dendrites. The tracing shows the excitatory state of group of neurons rather than of individual neurons, because the extracellular space is criss-crossed by currents from thousands of cells[1]. EEG tracings of living beings generally oscillate and are very irregular, but nevertheless follow a pattern. They may have a high-frequency component superimposed on low-frequency signals. Recent progress in the theory of nonlinear dynamical systems has provided new methods for the study of EEG time series data. Global properties of the brain EEG patterns at various stages of activity and inactivity, are being analysed using the theory of chaos, Lyapunov exponent, auto-correlation function, power spectra and fractal dimension[2–4]. Activity of a small subset of neurons in the presence and absence of a synchronized oscillatory signal is modelled using differential equations and the results analysed using spatial auto-correlation function and correlation dimension[5].

Neural network computer programs try to simulate neuronal activity. In an artificial neural network, the unit analogous to the biological neuron is referred to as a processing element (PE)[6,7]. In spite of the fact that simple interconnected networks do not completely simulate the dynamic properties of real neurons, they are useful in gaining insight into universal principles of distributed systems. Also, a trained network has striking similarities to actual neurons and can suggest functional roles of neurons with input and output that are hard to grasp intuitively. Back propagation network has been used to process chaotic EEG signals[8].

A neural network consists of many processing elements joined together through connection weights which correspond to the synaptic strength of neural connections. Data to the network is presented at input layer and the response of the network to the given data is stored in the output layer. It is speculated that the training or learning of neural network model is similar to the way humans or animals are trained by reinforcement technique, where certain synapses that connect the neurons selectively get strengthened leading to increase in the gain.

We attempt here to simulate the different types of EEG patterns emanating from human brain during activity (eyes closed and open, epileptic seizure stages) and inactivity (sleep stages 2, 4 and REM stages) using a general regression neural network model.

Back propagation partially recurrent and cascade correlation neural network models have been used to simulate non-average single trial multi-channel EEG data produced during the side finger movement[9]. The cascade correlation neural network model was found to predict the obs signals well.

Neural network models have been used to train on ECG signals of patients with anterior and myocardial infarction and the network was later used for prediction of abnormalities[10]. Back propagation model has also been used for detecting spikes and seizures during epileptic fits[11], for simulating the oscillatory activity observed in the visual cortex[12], and olfactory system[13]. Very little work is reported on simulating the EEG brain signals during various sleep stages, eyes open and closed stages. A trained neural network model can help in identifying sleep disorders, changes in sleep pattern and variation in sleep patterns between individuals.

Two networks that are well suited for modelling, prediction and classification are back-propagation (BP) and general regression neural network (GRNN)[14]. BP network is a general purpose nonlinear regression technique which attempts to minimize global error. The main advantages of the GRNN over the BP network are (i) it can handle non-stationary or noisy data; (ii) it can be effectively used with sparse data. This network was proposed by Donald Specht of the Lockheed Palo Alto Research Laboratory.

Each PE in the network has several inputs and outputs. The output path of a PE is connected to the input path of another PE through connection weight. The input signal is multiplied by the weight before it is sent to the PE. All the weighted signals are summed up and fed as the input to the PE. This signal is transformed and sent to the output path of the PE. A neural network normally has one input, one output and at least one hidden layer and, there may be several PEs in each layer. During learning stage the weights are manipulated so that for a given set of input signals, the outputs estimated by the network match the actual values.

GRNN uses a statistical equation for calculating the conditional mean Y of a scalar random variable y given a measurement X of a vector random variable x. The conditional mean is statistically the most probable value for the random variable Y for given X. The vector random variables x and y correspond to the ensemble of inputs and outputs of the network. The equation for conditional mean requires knowledge of the joint probability density function (PDF) of the random variable x and y.

In GRNN, the PDFs are obtained from the training vectors using Parzen estimation. Parzen estimation is a non-parametric estimation procedure which approximates a density function by constructing it out from many PDFs and, it takes the form of a Gaussian distribution (bell-shaped curve). The parameter used in the exponential term of the Gaussian equation is estimated from the input vectors and their centre and, is given by the square root of the sum of square of the difference between the input vectors and the centre. It is also known as the Euclidean distance (D_t). This type of summation is called Euclidean summation and is suitable for most of the problems. The estimate for the conditional mean for the output vector is given by

$$Y(X)=\frac{\sum_{t=1}^{T}[Y^{(t)}\exp(-D_t^2/2\sigma^2)]}{\sum_{t=1}^{T}[\exp(-D_t^2/2\sigma^2)]},$$

where $\{[X^{(t)}, Y^{(t)}]: t=1, \ldots T\}$ is a set of training sample input/output pairs, D_t is the Euclidean distance between x and $X^{(t)}$ and N is the number of input modes of the network.

$$D_t=\sqrt{\sum_{i=1}^{N}(x_i-X_i^{(t)})^2}.$$

σ, the width parameter $= S/T^{E/N}$, $0 < E < 1$.

At the start of the learning cycle, the number of pattern (or hidden) PE can be set to the number of data vectors in the training file and later changed depending upon the network performance. Three parameters which control the learning process are the radius of influence, reset factor and time constant.

If the input vectors or training samples are large, the estimate for conditional mean becomes both time and memory-intensive. So the input vectors are grouped together (or clustered) and the average value of the groups are used in the calculations in order to decrease the simulation time. Any input vector is assigned to a nearest group if its distance to the centre of a previously established kernel is less than the radius of influence, otherwise a new kernel is established. A very small value for radius of influence will lead to a large number of clusters and hence increased computational time. Whereas, a large value will give fewer clusters and hence loss of sensitivity and possibly poor data fit.

PEs whose contributions in the summation are very small are termed as non-winning PEs. All the output weights from each of these non-winning PEs are multiplied

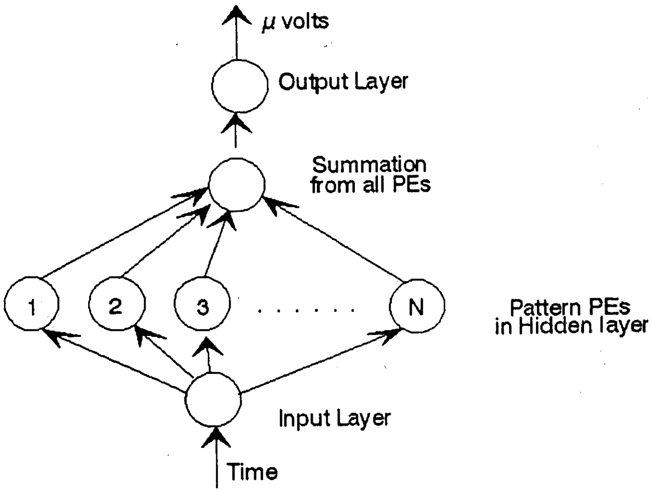

Figure 1. A general regression neural network for the EEG problem.

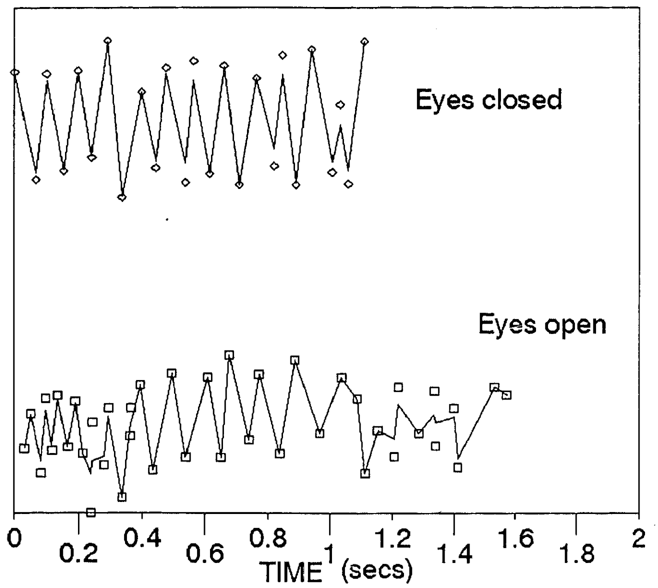

Figure 2. Comparison of human EEG data (points) and GRNN model simulation (continuous lines) during the stages of eyes open (9950 PEs) and eyes closed (1500 PEs). (Number of PEs required for simulation are given in brackets. *Y* axis is not to scale but presented arbitrarily to show the fit between the model and the simulation. *Y* axis ranges for eyes open and closed are 10 and 60 µV respectively.)

by a numeric term (called forgetting function), whose value decreases in an exponential fashion. The value of the time constant in the exponential term decides how fast the weights decay. When the weights become smaller than the ratio, reset factor/number of PEs, then the particular weight is set to zero. A large time constant could lead to slow decay of the weight from non-winning PE. The suggested value for radius of influence, reset factor and time constant are 0.05, 0.01 and 1000 respectively. In all the simulations about 10000 learning cycles were employed. Figure 1 shows a typical GRNN with a single input and single output, in this case time and µV respectively, and several pattern PEs in the hidden layer.

The EEG patterns were simulated by GRNN network. NeuralWorks Explorer (NeuralWare Inc., Pittsburgh, USA), a software running on a PC 386 equipped with a math coprocessor, was used for these studies[15]. The human EEG brainwave data were read from the figures given in references 3 and 4. The blown-up figures were scanned using a flat bed optical scanner, digitized and the data points were read into a computer program using a mouse and a cursor. The data points were uniformly spaced out in time. Time versus µV were read out from the digitized data. About 5000 data points were collected from each pattern signal, 80% of the data was used by the neural network model for fitting and the remaining 20% of the data was used for comparing model predictions with actual values.

The goodness-of-fit (root mean square error = RMSE) is obtained by calculating the square root of the mean of the sum-of-squares of the difference between model predictions and the actual data. Generally RMSE decreases as the PEs are increased. The simulations were performed by systematically increasing the number of PEs until the corresponding RMSE reaches a minimum value or remains unchanged. The PEs reported in the paper correspond to the lowest RMSE. In all the figures, points represent observed values and continuous lines are the neural network model predictions. In the figures only a few data points are shown for the sake of clarity. Also, data points near peaks and valleys are shown because maximum differences are generally expected between model predictions and data at these points.

An alert and active brain produces beta waves, which are high frequency low amplitude events (~ 10 µV) (ref. 4). As the eyes are closed, the relaxing individual produces alpha waves, with an average frequency of 10 cycles/s and amplitudes of the order of 60 µV. Alpha waves are well ordered and much more coherent than beta waves. Figure 2 shows the comparison of EEG data with simulation of both these waves with a GRNN network model. The alpha waves were simulated with 1500 PEs, whereas the beta waves were simulated with 9900 PEs. Both the simulations were carried out with 10,000 learning cycles and, radius of influence of 0.0001. A very low radius of influence indicates that no clustering of PEs was done. From the figure it could be noticed that the model is able to predict the observed behaviour reasonably well. Beta waves have fine structure, hence require more PEs (by an order of 6.5) to simulate than the well-ordered alpha waves. As the brain reaches a relaxed stage (alpha) from an alert one (beta), the number of neurons in an active state in the brain possibly decreases, which is very clearly seen from the number of PEs required for simulation.

In sleep the individual drifts in and out of four stages of sleep. Sleep stage 2 is a light stage, with slightly coherent waves of amplitude of 70 µV. Sleep stage 4, is a deep sleep stage, with amplitude of 120 µV and about 3–5 cycle/s. The four stages of sleep are followed by the rapid eye movement sleep (REM) in which he dreams. In the REM stage the cerebral activity reverts to a non-coherent state, with an amplitude of about 30 µV. All these three sleep stages are simulated with a GRNN network having 4000, 2000 and 2500 PEs respectively. Figure 3 compares the data with the simulation. As the sleep enters the deep stage 4 from stage 2, the number of PEs decreases by half, indicating that the number of neurons active in the brain also decreases, possibly by half. The number of PEs required to simulate REM sleep is more than that required to simulate sleep stage 4, but less than that required to simulate stage 2. The EEG brain wave data shown in Figures 2 and 3 were taken from reference 4.

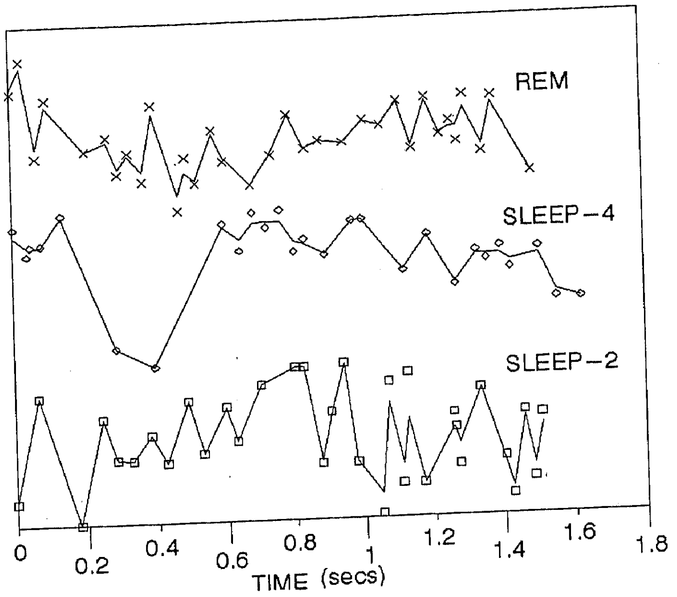

Figure 3. Comparison of human EEG data (points) and GRNN model simulation (continuous lines) during sleep stage 2 (4000 PEs), sleep stage 4 (2000 PEs) and REM sleep (2500 PEs). (Number of PEs required for simulation are given in brackets. *Y* axis is not to scale but presented arbitrarily to show the fit between the model and the simulation. *Y* axis ranges for sleep stages 2, 4 and REM are 70,120 and 30 μV respectively.)

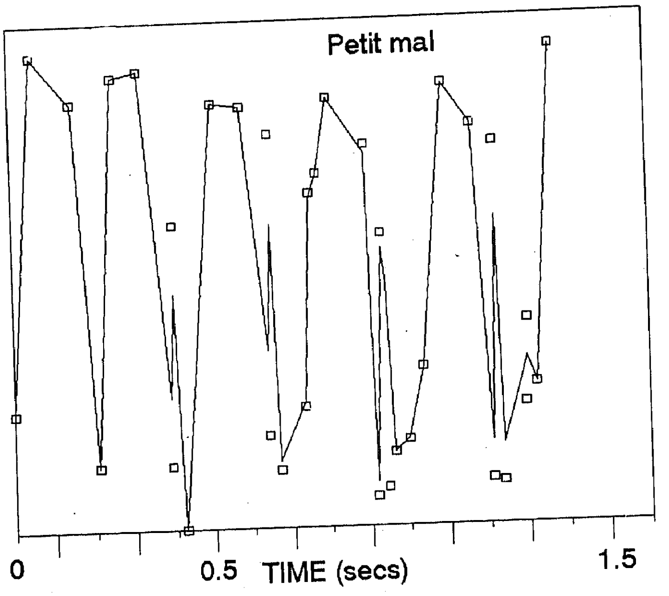

Figure 4. Comparison of human EEG data (points) and GRNN model simulation (continuous line) during petit mal seizure (5000 PEs). (Number of PEs required for simulation are given in brackets. *Y* axis range for petit mal seizure is 120 μV.)

There are several forms of epilepsy and, seizure of short duration (~5 s) is known as 'petit mal'[3]. This type generally invades the entire cerebral cortex and shows a bilateral symmetry between the two hemispheres. During the seizure the EEG activity switches to an apparent oscillating mode. Figure 4 compares the data and the simulation carried out with a GRNN network, of the EEG pattern of the epileptic stage with 5000 PEs. The model appears to simulate the epileptic waves fairly well. It appears that the number of neurons taking part during the seizure is more than the normal REM stage but less than the eyes open active stage. The EEG data of 'petit mal' was taken from reference 3.

Table 1. Comparison of human cerebral activity, number of PEs required in the GRNN neural network model for simulation and the fractal dimension of the EEG signals

Activity	Number of PEs required for simulation	Fractal dimension (from refs 2–4)
Eyes open	9950	9.7
Eyes closed	1500	6.6
Sleep stage 2	4000	5.0
Sleep stage 4	2000	4.05
REM	2500	8.2
Petit mal	5000	2.05

Table 1 lists the number of PEs required for simulating the EEG waves at various stages of brain activity. It also gives the fractal dimension, which is a measure of the minimum number of variables required to describe the signal[2–4]. Fractal dimension also measures the temporal coherence of the phenomena and follows qualitatively the degree of arousal. The fractal dimension decreases from the eyes open to the eyes closed stages, and so does the number of PEs required for simulating these two states. A similar trend in fractal dimension and number of PEs is observed in the case of sleep stages 2 and 4. Although the fractal dimension in the case of REM sleep is high, the number of PEs required for simulation is low. The fractal dimension of the EEG signals during the REM stage and epileptic seizure are 8.2 and 2.05 respectively, indicating a large reduction in the complexity of the signals. The neural network model studies indicate that the number of PEs required for both these stages are 2500 and 5000 respectively. The PEs required for simulating 'petit mal' seizure should have been much lower than this value. The RMSE in all cases is of the order of 0.05 to 0.07 (error margin of about 5 to 7%), indicating a good data fit.

This paper describes the modelling and simulation of the EEG patterns observed during the various stages of human activities. The simulations were carried out with general regression neural network model. The number of neurons required to simulate the EEG patterns and rhythms could be reasonably explained based on the brain activity. Most number of PEs are required to simulate beta waves observed during an active brain with eyes open. This is followed by 'petit mal' seizure. A correlation exists between number of PEs and fractal dimension in some cases. It should be borne in mind that the number of PEs required for simulating a particular activity estimated from modelling, cannot be equal to the number of neurons in the brain taking part in the activity. But, the ratio of PEs estimated by modelling for two activities may be an indication of the ratio of active neurons in the brain during two activities. Although another neural network model, namely back propagation model, was not able to fit these EEG patterns, other neural network models could also be attempted.

**Department of Microbiology, King George's Medical College,
Lucknow 226 001, India

The response of IgG subclasses to diethylcarbamazine (DEC) treatment was studied in bancroftian filariasis patients. On the basis of clinical signs and parasitological examination, a total of 22 patients were categorized into asymptomatic microfilaraemics (AS-Mfmic; $n = 12$) and symptomatic amicrofilaraemics (S-AMfmic; $n = 10$). The subjects were treated with DEC (300 mg/day) for 21 days. Before treatment, AS-Mfmic cases showed higher levels of IgG_1 and IgG_4 than the S-AMfmics whereas IgG_2 was higher in S-AMfmics than in AS-Mfmics. DEC caused more than 90% reduction in microfilaraemia by day 30 since the start of treatment in AS-Mfmics, while S-AMfmics remained amicrofilaraemic throughout the study period. In AS-Mfmics, DEC treatment enhanced IgG_4 and decreased IgG_1 levels while IgG_2 and IgG_3 remained unaffected. In S-AMfmics, DEC treatment caused decrease in IgG_1, IgG_3 and IgG_4, while IgG_2 level remained unchanged. We report that DEC therapy brings about changes in specific IgG_1 and IgG_4 in AS-Mfmics and IgG_1, IgG_3 and IgG_4 in S-AMfmics.

FILARIAL parasite initiates immune response in its host at both cellular and humoral levels. Clinical expression of filariasis, therefore, reflects not only the duration and intensity of infection but also the degree and character of different types of immunologic responses. Asymptomatic microfilaria (mf) carriers have depressed antibody- and cell-mediated immune responses while acute manifestations and chronicity are associated respectively with an intermediate and hyper-immune response[1–4].

The major immunoglobulins involved in the antifilarial antibody responses in human host are IgG, IgM, and IgE[3,5,6]. IgG is the major immunoglobulin detectable in all categories of filarial subjects and the clinical severity of the infection is directly related to this isotype[7]. Recent studies have also shown that different categories of filarial subjects have different IgG subclass profiles. Specific IgG_1 and IgG_3 are predominant in chronic lymphatic filariasis whereas IgG_4 is elevated in mf carriers and tropical pulmonary eosinophilia cases[8,9]. As IgG_4 was suggested to indicate the presence of parasites[8,10], Wamae *et al.*[11] used it as an indicator of adulticidal efficacy of diethylcarbamazine (DEC) or ivermectin in microfilaraemic (bancroftian) human subjects. However, whether DEC can also bring about alteration in other subclass responses in bancroftian filarial patients is not known. We report here the response of IgG subclasses to DEC treatment (shortly after cessation of the treatment) in symptomatic amicrofilaraemic and asymptomatic microfilaraemic bancroftian patients.

Patients reporting to the outdoor clinic of King George's Medical College, Lucknow for treatment of various ailments, were examined for filariasis. The patients were from Lucknow and its adjoining areas which are known to be endemic to bancroftian filariasis. A total of 22 patients diagnosed clinically and parasitologically positive for filariasis were included in the study. Of these, 12 subjects were asymptomatic with microfilaraemia (AS-Mfmic) while 10 had symptoms of 3–4 years duration (elephantiasis of legs and/or hydrocele) but amicrofilaraemic (S-AMfmic). Microfilariae (mf) in venous blood (1 ml; collected between 9 and 11 pm) were assessed using the membrane filtration technique[12]. For the assay of IgG and its subclasses, serum was separated from blood and stored at –20°C till use.

---

*For correspondence.

All the AS-Mfmic and S-AMfmic subjects received diethylcarbamazine (DEC) at 300 mg/day for 21 days. Venous blood was collected before therapy and one week after the last dose. Treated patients were examined daily during and after the therapy for any adverse reactions.

Brugia malayi adult worms were harvested from intraperitoneal cavity of jirds infected intraperitoneally with *B. malayi* L_3. Soluble somatic extract of the worms was prepared as described by Lammie *et al.*[13] and used as the antigen source. The protein content of the extract was determined by the method of Lowry *et al.*[14].

Circulating antifilarial IgG subclasses were assessed by ELISA as described by Hussain *et al.*[15], with some modifications. Briefly, polystyrene plates were coated overnight at 4°C with the antigen (10 µg/ml) in carbonate buffer. Unsaturated sites of the surface were blocked with 1% gelatin in phosphate buffered saline (G-PBS) for 1 h at 37°C, and the plates were incubated with sera diluted (1:25) in G-PBS containing 0.01% Tween-20 (G-PBS-T) for 90 min at 37°C. The plates were washed with PBS-T and incubated with optimally diluted mouse monoclonal anti-human IgG_1 (1:7,500), IgG_2 (1:5000), IgG_3 (1:5000) and IgG_4 (1:7500) for 90 min at 37°C. The plates were again washed and incubated for 90 min at 37°C with 1:1000 dilution of anti-mouse IgG-peroxidase conjugate. The plates were washed and incubated in the substrate medium consisting of 0.08% each of *o*-phenylenediamine and H_2O_2 in citrate buffer (pH 5.0). After stopping the reaction with 2.5N H_2SO_4, the optical density was read at 492 nm using an automated ELISA reader (Multiscan). All the antibodies and conjugates were from Sigma Chemical Co., St. Louis.

The values of the IgG subclasses in the two categories of the patients were compared by Student's *t* test. Paired *t* test was applied for the analysis of effects of DEC treatment on the responses. Differences were considered significant if $p \leq 0.05$.

The concentration of specific IgG subclasses (IgG_1, IgG_2, IgG_3 and IgG_4) in sera of AS-Mfmic and S-AMfmic cases before and after DEC treatment is shown in Figure 1.

Amongst the four subclasses of IgG, the levels of IgG_4 alone and IgG_2 and IgG_4 were significantly elevated ($p < 0.01$) respectively in AS-Mfmic and S-AMfmic cases. When the values of the 4 IgG sub-classes were compared between the two groups, the responses of IgG_1 and IgG_4 were significantly higher ($p < 0.01$) in AS-Mfmic while IgG_2 was greater in S-AMfmic cases ($p < 0.05$).

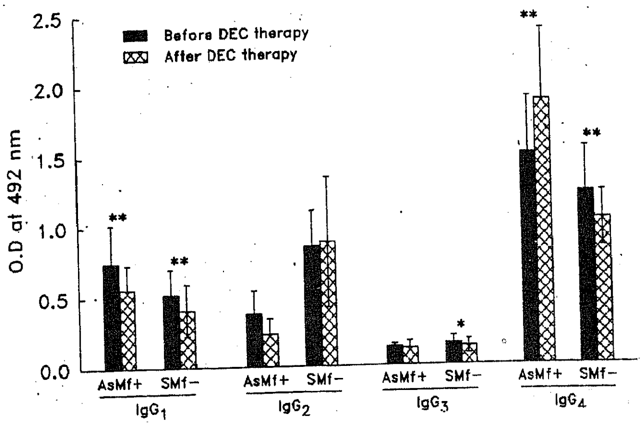

Figure 1. IgG subclasses in asymptomatic microfilaraemics and symptomatic amicrfilaraemics before and after DEC therapy (*$p < 0.05$; **$p < 0.01$).

By day 30 post-DEC treatment, there was more than 90% reduction (88.29–98.33%) in microfilaraemia in AS-Mfmic cases while the S-AMfmic patients remained amicrofilaraemic (data not shown). There was no amelioration of manifestations in S-AMfmic cases nor any appearance/development of tenderness in any part of the body in AS-Mfmic cases during the course of treatment.

In AS-Mfmic subjects, DEC treatment decreased the antifilarial IgG_1 response ($p < 0.01$) but increased specific IgG_4 response ($p < 0.01$). IgG_2 and IgG_3 responses were not affected by DEC therapy.

In S-AMfmic cases, DEC treatment resulted in decrease in IgG_1 ($p < 0.01$) and IgG_4 ($p < 0.01$), and IgG_3 ($p < 0.05$) whereas IgG_2 remained unaffected.

Responses of IgG subclasses (IgG_1, IgG_2, IgG_3 and IgG_4) have been reported for chronic helminthic diseases, namely, filariasis, schistosomiasis and cysticercosis; IgG_4 was found to be the most dominant subclass in these diseases[16–18] though it accounts for only 3–4% of the total IgG in normal human serum[19]. The present study revealed that in the untreated subjects the concentration of subclass IgG_4 was maximum in AS-Mfmics while IgG_2 and IgG_4 concentrations were raised in S-AMfmic subjects. Inter-category comparison showed that IgG_1 and IgG_4 were higher in AS-Mfmics than in S-AMfmics, whereas IgG_2 was higher in S-AMfmics than in AS-Mfmics.

A significantly high level of IgG_1, as found in AS-Mfmics in this study, was also reported by Mak *et al.*[20] in brugian microfilaraemic patients but not in bancroftian microfilaraemics. S-AMfmic cases had high IgG$_2$ compared to AS-Mfmic patients which supports the findings of Rahmah *et al.*[21] in malayan filariasis. These authors even suggested that IgG$_2$ may be used as diagnostic tool for *B. malayi*-induced chronic elephantiasis. On the other hand, Ottesen *et al.*[8] reported elevated antifilarial IgG$_1$ and IgG$_4$ but not IgG$_2$ in patients with chronic elephantiasis due to *W. bancrofti* infection.

IgG$_3$ was lower than other subclasses in both the categories of subjects. This is in contrast to the findings of Hussain *et al.*[15] who found low IgG$_3$ levels only in AS-Mfmic bancroftian filarial cases. AS-Mfmic brugian cases, on the other hand show elevated levels of IgG$_3$ (ref. 20).

We found elevated IgG$_4$ levels in both AS-Mfmics and S-AMfmic patients. Ottesen *et al.*[8], Hussain *et al.*[15], Lal and Ottesen[9] and Kwan-Lim *et al.*[22] reported predominance of IgG$_4$ antibody response not only in mf (*W. bancrofti*) carriers but also in tropical pulmonary eosinophilia cases.

Significant variations have been reported in the levels of IgG subclasses in filarial subjects. Although no explanation is forthcoming for this disparity, the strain of parasite prevalent, the immune status of population studied and many other associated factors might be responsible for these variations.

DEC treatment resulted in significant decrease in IgG$_1$ levels in AS-Mfmics and IgG$_1$, IgG$_3$ and IgG$_4$ levels in S-AMfmics. While the present studies were in progress, Atmadja *et al.*[23] reported a decrease in IgG$_1$ and IgG$_4$ levels 12 months after DEC therapy in *malayan* microfilaraemic and elephantiasis patients. However, they reported a fall in IgG$_2$ as well as IgG$_3$ in elephantiasis patients while our present study showed no change in IgG$_2$ response in S-AMfmics by day 30 since the initiation of treatment. In view of the known role of IgG$_1$ and IgG$_3$ in hypersensitivity/allergic (Type III) reactions[24] which lead to tissue damage and the recent report of Casley-Smith *et al.*[25] that DEC reduced lymphoedema in chronic symptomatics, these two IgG sub-classes may be involved in the responses to DEC treatment in symptomatic amicrofilaraemic bancroftian subjects. In AS-Mfmics on the other hand, IgG$_1$ is evidently involved in the responses to DEC treatment. It is interesting to note that recently, using lymphoscintigraphy, lymphatic tissue pathology was demonstrated in asymptomatic microfilaraemics also[26]. If IgG$_1$ is involved in tissue pathology seen in asymptomatic microfilaraemics, as suggested by the above reports, our results indicate that this subclass in combination with IgG$_4$ (discussed below) may be useful as a convenient tool for assessing the response of microfilaraemics to DEC therapy.

In AS-Mfmic subjects, IgG$_4$ levels were increased by DEC treatment by day 30 since the initiation of therapy. This confirms the recent finding of Wamae *et al.*[11] who found increased IgG$_4$ levels at day 30 since start of a twelve-day course of DEC therapy in bancroftian microfilaraemics which decreased significantly to below pretreatment levels by day 180. As suggested by these authors, the increase in IgG$_4$ levels in our microfilaraemic subjects is related to sudden release of microfilarial antigen(s). The significant reduction (more than 90%) in microfilaraemia found in our subjects supports this suggestion.

In conclusion, the DEC therapy brings about changes in specific IgG$_1$ and IgG$_4$ in bancroftian AS-Mfmics and in IgG$_1$, IgG$_3$ and IgG$_4$ sub-classes in S-AMfmics. Assessment of IgG subclass levels in AS-Mfmics and S-AMfmics may possibly be used as a convenient tool for monitoring the infection and especially the clinical status of the disease following antifilarial therapy.

Synthesis and antitumour activity of new derivatives of podophyllotoxin

Pan Jian-lin*, Wang Yan-guang* and Chen Yao-zu*†

*Department of Chemistry, Zhejiang University, Hangzhou 310 027, P.R. China
†State Key Laboratory of Applied Organic Chemistry, Lanzhou University, Lanzhou 730 000, P.R. China

A series of new podophyllotoxin derivatives 3–8 have been synthesized and evaluated for their antitumour activity *in vitro*. Compounds 3 and 8 exhibited comparable or superior activity to clinically used etoposide (VP-16, 2) in their inhibition of human stomach carcinoma SGC-7901, lung cancer A 549, and mouse leukemia P388 cells.

SEMISYNTHETIC analogues of the naturally-occurring podophyllotoxin (**1**) have drawn much renewed interest in recent years as a result of the development of etoposide (VP-16, **2**) and teniposide (VM-26) as anticancer drugs[1,2]. It is believed that analogues of 4′-demethylepipodophyllotoxin exert their antitumour activity through stabilization of a cleavable complex between DNA and type II DNA topoisomerase. This leads ultimately to inhibition of DNA catenation activity and produces single and double strand breaks[3,4].

In our previous studies[5–8], we found that substitution of the glycosidic moiety in **2** by a configurationally similar nitrogen-containing group led to some compounds which have comparable or superior antitumour activity to **2**. The results suggested that the β-anomeric configuration at C-4 was indispensable for the antitumour activity. Changes in the 4β-glycosyl group are also of interest for simplified structure which might retain the activity of **2**, and be accessible to practical industrialization. Here we wish to present the synthesis of a series of new analogues of epipodophyllotoxin **3–8** and their biological activities *in vitro*.

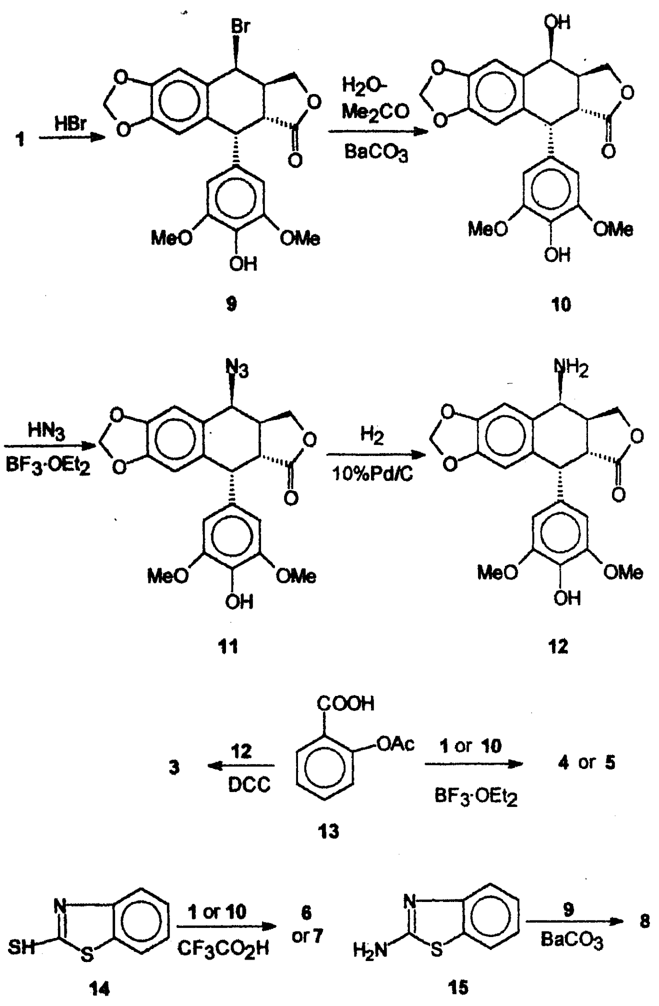
Scheme 1.

The synthesis of target compounds started from **1** as shown in Scheme 2. 4β-bromo-4′-demethyl-4-deoxypodophyllotoxin (**9**) and 4′-demethylepipodophyllotoxin (**10**) were prepared from **1** by our previous procedure[5,9]. **10** was treated with HN_3 to yield 4β-azido-4′-demethyl-4-deoxypodophyllotoxin (**11**) as the major product, which was accompanied by the C-4 isomer product, 4α-azido-4′-demethyl-4-deoxypodophyllotoxin, **11** can be purified by crystallization. Further reduction of **11** led to 4β-amino-4′-demythyl-4-deoxypodophyllotoxin (**12**). Condensation of **12** with aromatic acid **13** in the presence of DCC gave compound **3**. Compounds **4** and **5** were synthesized by the reaction of **13** with **1** and **10**, respectively. Thio-etherification of **1** and **10** with 2-mercaptobenzothiazole (**14**) yielded compounds **6** and **7**, respectively. Compound **8** was synthesized by direct substitution of 2-amino-benzothiazole (**15**) with 4β-bromo-4′-demethyl-4-deoxypodophyllotoxin (**9**).

All new target compounds were characterized by m.p., ^{1}H NMR, MS and IR spectral analysis, as well as elemental analysis. The assignment of the configuration at C-4 for compounds **3–8**, **11** and **12** was based on the difference of $J_{3,4}$ coupling constants. The C-4β-substituted compounds **3–8**, **11** and **12**, have a $J_{3,4} \approx 4.0$ Hz as seen in **2** and **10** (ref. 10), due to a *cis*



Scheme 2.

Table 1. Cytotoxicity of compounds 3–8

Compound	ID50 (μM)		
	P388	SGC-7901	A549
VP-16(2)	0.012	0.32	0.44
3	0.0082	0.38	0.20
4	0.65	0.86	0.90
5	0.32	0.60	0.84
6	0.20	>10	0.40
7	0.26	>10	2.3
8	0.020	0.40	0.24

relationship between H-3 and H-4. The C-4α-substituted derivatives, however, like **1**, have a $J_{3,4} \geq 10.0$ Hz as H-3 is *trans* to H-4 (ref. 10).

We have tested the inhibitory activities of compounds **3–8** against human stomach carcinoma SGC-7901, lung cancer A549 and mouse lymphocytic leukemia P388 cells *in vitro*. As illustrated in Table 1, compounds **3** and **8** are as active or more active than VP-16 (**2**) in their inhibition of P388 and SGC-7901 cells, while compounds **3**, **6** and **8** are more potent than VP-16 in their inhibition of A 549 cells. Therefore, compounds **3** and **8** have comparable or superior antitumour activity to VP-16 (**2**). These results demonstrate the possibility of considerable simplification in the sugar structure of VP-16 and suggest further elaboration of 4β-nitrogen-containing substituent to optimize the structure of this class of anticancer compounds. Further study for antitumour activity of compounds **3** and **8** is in progress.

All melting points were taken on Yanaco melting point apparatus and uncorrected IR spectra were obtained on a Nicolet-5DX spectrophotometer, and ^{1}H NMR spectra were obtained by using either a Broker AM-400 or JMS-FX-90Q NMR spectrometer, all chemical shifts were reported in ppm from TMS. Elemental analyses were determined on a Carlo Elba 1106 instrument. Mass spectral analyses were taken on a V.G. ZAB-HS instrument at 70 eV with a direct inlet system.

4β-Azido-4′-demethyl-4-deoxypodophyllotoxin (**11**): To a solution of a mixture of 5.0 g (12.5 mmol) of **10** in 175 ml of anhydrous CH_2Cl_2 and 13 mmol HN_3 in benzene (10 ml) was added dropwise $BF_3.OEt_2$ (2.25 ml) at −16°C. The mixture was stirred at −16°C for 1 h. After being quenched with pyridine (2.25 ml), the solution was washed with water and dried over Na_2SO_4. Evaporation of the solvent gave a solid, which was checked by TLC and NMR analyses to be a mixture of 4α- and 4β-isomers (ca. 1:8). Crystallization from acetone/methanol provided 4β-isomer (**11**). Yield 91%, m.p. 213–214°C; MS m/z $[M]^+$ 425; IR (KBr) 3406 (OH), 2096 (azide), 1762 (lactone), 1610, 1520 and 1484 (aromatic C=C) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ 6.82 (s, 1H, H-5), 6.58 (s, 1H, H-8), 6.27 (s, 2H, H-2′, 6′), 6.01 (d, 2H, OCH_2O), 5.47 (s, 1H, 4′-OH), 4.81 (d, $J = 4.0$ Hz, 1H, H-4), 4.63 (d, $J = 4.4$ Hz, 1H, H-1), 4.32 (d, $J = 9.5$ Hz, 2H, H-11), 3.78 (s, 6H, 3′, 5′-OCH_3), 3.17 (dd, $J = 4.4$, 12.6 Hz, 1H, H-2), 2.93 (m, 1H, H-3); Anal. calcd for $C_{21}H_{19}N_3O_7$, C59.29, H4.50, N9.88; found C59.15, H4.51, N9.77.

4β-Amino-4′-demethyl-4-deoxypodophyllotoxin (**12**): To a solution of 5.0 g (11 mmol) of **11** of 100 ml of EtOAc was added 1.0 g of 10% palladium on carbon. This mixture was shaken under 40 psi of H_2 for 16 h. The reaction mixture was filtered through celite and the filtrate evaporated *in vacuo*. Crystallization from methanol gave 3.1 g of pure **12**, yield 68%, m.p. 212–214°C; MS m/z $[M]^+$ 399; IR (KBr) 3360 (OH), 3290 (NH_2), 1745 (lactone), 1610, 1525 and 1485 (aromatic C=C) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ 6.81 (s, 1H, H-5), 6.49 (s, 1H, H-8), 6.30 (s, 2H, H-2′, 6′), 5.96 (d, 2H, OCH_2O), 5.06 (s, 1H, 4′-OH), 4.55 (d, $J = 5.2$ Hz, 1H, H-1), 4.28 (d, $J = 9.5$ Hz, 2H, H-11), 4.20 (d, $J = 4.1$ Hz, 1H, H-4), 3.77 (s, 6H, 3′,5′-OCH_3), 3.28 (dd, $J = 5.2$, 14 Hz, 1H, H-2), 2.85 (m, 1H, H-3) ppm; Anal.

calcd for $C_{21}H_{21}O_7N{\cdot}H_2O$, C60.43, H5.55, N3.36, found C60.52, H5.54, N3.38.

Compound **3**: 0.20 g (0.5 mmol) of **12** was dissolved in 20 ml of dried CH_2Cl_2, 0.09 g (0.5 mmol) of acetyl salicylic acid (**13**) and 0.10 g (0.5 mmol) of DCC were added, respectively. The reaction mixture was stirred at room temperature for 5 h. Two drops of acetic acid was added. The reaction mixture was filtered. The filtrate was washed with saturated solution of $NaHCO_3$, 10% hydrochloric acid and water, respectively, dried over anhydrous Na_2SO_4, and chromatographed through silica gel using $CHCl_3$-Me_2CO (6:1) as eluent. The pure product **3** (0.14 g, 5%) was crystallized from $CHCl_3$, m.p. 214–216°C; MS m/z $[M]^+$ 561; IR (KBr) 3400–3500 (OH, NH), 1765 (lactone), 1710 (ester), 1690 (CONH), 1610, 1510 and 1480 (aromatic C=C) cm^{-1}; ^1H NMR ($CDCl_3$) δ 7.14–7.78 (m, 4H, H-3″, 4″, 5″, 6″), 6.92 (s, 1H, H-5), 6.56 (s, 1H, H-8), 6.32 (s, 2H, H-2′, 6′), 5.99 (d, 2H, OCH_2O), 5.42 (s, 1H, 4′-OH), 4.64 (d, $J = 4.0$ Hz, 1H, H-4), 4.50 (d, $J = 5.0$ Hz, 1H, H-1), 4.20 (d, $J = 9.8$ Hz, 2H, H-11), 3.60 (s, 6H, 3′, 5′-OCH_3), 2.96 (m, 2H, H-2, 3), 2.21 (s, 3H, 2″-$OCOCH_3$) ppm; Anal. calcd for $C_{30}H_{27}NO_{10}$, C64.17, H4.81, N2.50, found C63.81, H4.81, N2.38.

Compound **4**: To a solution of 1.5 g (3.6 mmol) of **1** and 0.65 g (3.6 mmol) of **13** in 50 ml of dried $CHCl_3$ was added dropwise $BF_3{\cdot}OEt_2$ (0.8 ml) at –16°C. The mixture was stirred at –16°C for 1 h. After quenched with pyridine (0.8 ml), the mixture was washed with water, dried over anhydrous Na_2SO_4, chromatographed on a silica gel column using $CHCl_3$-Me_2CO (7:1) as eluent, and crystallized from CH_2Cl_2 to give 1.0 g of pure product **4**. Yield 50%, m.p. 111–113°C; MS m/z $[M]^+$ 576; IR (KBr) 1778 (lactone), 1700 (ester, 1624, 1585 and 1487 (aromatic C=C) cm^{-1}; ^1H NMR ($CDCl_3$) δ 7.21–7.91 (m, 4H, H-3″, 4″, 5″, 6″), 6.91 (s, 1H, H-5), 6.60 (s, 1H, H-8), 6.35 (s, 2H, H-2′, 6′), 6.01 (d, 2H, OCH_2O), 4.75 (d, $J = 4.2$ Hz, 1H, H-4), 4.42 (d, $J = 5.0$ Hz, 1H, H-1), 4.20 (m, 2H, H-11), 3.82 (s, 3H, 4′-OCH_3), 3.75 (s, 6H, 3′, 5′-OCH_3), 3.15 (m, 2H, H-2, 3), 2.20 (s, 3H, 2″-$OCOCH_3$) ppm; Anal. calcd for $C_{31}H_{28}O_{11}$, C64.58, H4.86, found C64.50, H4.77.

Compound **5**: **5** was synthesized from **10** by the similar procedure for the preparation of **4** from **1**. Yield 46%, m.p. 202–203°C; MS m/z $[M]^+$ 562; IR (KBr) 3367 (OH), 1778 (lactone), 1712 (ester), 1624, 1568 (aromatic C=C) cm^{-1}; ^1H NMR ($CDCl_3$) δ 7.90 (m, 1H, H-6″), 7.60 (m, 1H, H-5″), 7.35 (m, 1H, H-4″), 7.19 (m, 1H, H-3″), 6.91 (s, 1H, H-5), 6.61 (s, 1H, H-8), 6.33 (s, 2H, H-2′, 6′), 6.01 (d, 2H, OCH_2O), 5.46 (s, 1H, 4′-OH), 4.74 (d, $J = 4.3$ Hz, 1H, H-4), 4.40 (d, $J = 5.1$ Hz, 1H, H-1), 4.15 (m, 2H, H-11), 3.61 (s, 6H, 3′, 5′-OCH_3), 3.10 (m, 2H, H-2, 3), 2.16 (s, 3H, 2″-$OCOCH_3$) ppm, Anal. calcd for $C_{31}H_{26}O_{11}$, C64.06, H4.63, found C64.27, H4.78.

Compound **6**: To a stirred mixture of 1.5 g (3.6 mmol) of **1** and 0.61 g (3.6 mmol) of 2-mercaptobenzothiazole (**14**) was added dropwise 19 ml of F_3CCOOH at –10°C. The reaction solution was stirred at room temperature for 3 h. Removal of the solvent yielded a residue, which was chromatographed on a silica gel column using $CHCl_3$-Me_2CO (7:1) as eluent, and crystallized from ethanol to obtain 0.85 g of **6**, yield 42%, m.p. 121–123°C, MS m/z $[M]^+$ 563; IR (KBr) 1772 (lactone), 1612, 1540 and 1490 (aromatic C=C) cm^{-1}; ^{1}HNMR ($CDCl_3$) δ 7.29–7.64 (m, 4H, H-4″, 5″, 6″, 7″), 7.00 (s, 1H, H-5), 6.58 (s, 1H, H-8), 6.38 (s, 2H, H-2′, 6′), 6.00 (d, 2H, OCH_2O), 4.67 (d, $J = 4.2$ Hz, 1H, H-4), 4.40 (d, $J = 5.2$ Hz, 1H, H-1), 4.17 (d, $J = 9.5$ Hz, 2H, H-11), 3.82 (s, 3H, 4′-OCH_3), 3.75 (s, 6H, 3′, 5′-OCH_3), 3.23 (m, 2H, H-2, 3) ppm; Anal. calcd for $C_{29}H_{25}NO_7S_2$, C61.81, H4.44, N2.49, found C61.58, H4.37, N2.47.

Compound **7**: It was obtained from **10** by the similar procedure for the preparation of **6** from **1**. Yield 61%, m.p. 207–209°C; MS m/z $[M]^+$ 549; IR (KBr) 3400 (OH), 1778 (lactone), 1620, 1571 and 1485 (aromatic C=C) cm^{-1}; ^{1}HNMR ($CDCl_3$) δ 7.28–7.83 (m, 4H, H-4″, 5″, 6″, 7″), 7.02 (s, 1H, H-5), 6.52 (s, 1H, H-8), 6.37 (s, 2H, H-2′, 6′), 5.99 (d, 2H, OCH_2O), 5.47 (s, 1H, 4′-OH), 4.66 (d, $J = 4.2$ Hz, 1H, H-4), 4.48 (d, $J = 5.2$ Hz, 1H, H-1), 4.22 (d, $J = 10$ Hz, 2H, H-11), 3.63 (s, 6H, 3′,5′-OCH_3), 3.20 (m, 2H, H-2, 3) ppm; Anal. calcd for $C_{28}H_{23}NO_7S_2$, C61.20, H4.17, N2.55, found C60.99, H4.15, N2.35.

Compound **8**: A mixture of 0.47 g (1 mmol) of **9**, 0.25 g (1.7 mmol) of 2-aminobenzothiazole (**15**) and 0.23 g (1.1 mmol) of $BaCO_3$ in 10 ml of $ClCH_2CH_2Cl$ was stirred at room temperature for 24 h. The reaction mixture was filtered, diluted with ethylacetate, washed with water, dried over anhydrous magnesium sulphate, and purified via silica gel column chromatography using $CHCl_3$-Me_2CO (7:1) as eluent. Crystallization from ethyl acetate provided 0.26 g of **8**, yield 49%, m.p. 218–220°C; MS m/z $[M]^+$ 532; IR (KBr) 3550–3412 (OH, NH), 1774 (lactone), 1600, 1530 and 1487 (aromatic C=C) cm^{-1}; ^1H NMR ($CDCl_3$) δ 7.54–7.16 (m, 4H, H-4″, 5″, 6″, 7″), 6.91 (s, 1H, H-5), 6.54 (s, 1H, H-8), 6.36 (s, 2H, H-2′, 6′), 5.98 (d, 2H, OCH_2O), 5.44 (s, 1H, 4′-OH), 5.20 (br, 1H, NH), 4.59 (d, $J = 4.0$ Hz, 1H, H-4), 4.40 (d, $J = 5.0$ Hz, 1H, H-1), 4.18 (d, $J = 9.5$ Hz, 2H, H-11), 3.80 (s, 6H, 3′, 5′-OCH_3), 3.04 (m, 2H, H-2, 3) ppm; Anal. calcd for $C_{28}H_{24}N_2O_7S$, C63.16, H4.51, N5.26, found C62.98, H4.56, N5.17.

Embryogenic calli were obtained from hypocotyl explants of groundnut (*Arachis hypogaea* L.) cultured on a medium containing different concentrations of 2,4-D or NAA in combination with 0.5 mg/l BAP. Type of auxin, concentration and genotypes influenced somatic embryogenesis. 2,4-D was found to be the best somatic embryo inductor. As the auxin level increased beyond 20 mg/l in induction medium, both per cent as well as number of embryos were decreased. 2,4-D (20 mg/l) was found to be better than NAA for the induction of globular and heart-shaped somatic embryos. Somatic embryos developed from these calli following transfer to a medium supplemented with 0.5 mg/l 2,4-D and 2.0 mg/l BAP was found to be best for embryo maturation. The well-formed embryos germinated into plantlets on MS medium supplemented with BAP (0.5–2.0 mg/l) and NAA (0.25 mg/l). The regenerated plants were transferred to soil and grown to maturity. Hardened plantlets produced normal flowers and set viable seeds. The ability of this regeneration system to produce embryos exponentially offers potential for development of new gene transfer technology and application to synseed technology.

GROUNDNUT (*Arachis hypogaea* L.) is an important grain legume and its improvement programmes include development of varieties resistant to diseases like tikka (*Cercospora arachidicola* and *Cercosporidium personatum*), rust (*Puccinia arachidis*) and pest (red hairy caterpillar). An efficient regeneration protocol either by organogenesis or somatic embryogenesis is a major prerequisite for the application of gene transfer methods for crop improvement. Regeneration by organogenesis from various explants, viz. leaves, cotyledons, cotyledonary node, hypocotyl, epicotyl, zygotic embryos has been reported[1–6]. But regeneration frequency was low and plants were rarely established. A number of recent reports describe somatic embryogenesis in peanut using a variety of different explants, including leaves[7,8], immature cotyledons[9,10] and immature embryo axes[11,12]. In spite of these studies, efficient protocol for regeneration of plantlets via somatic embryogenesis is lacking[13]. This study describes the successful induction of somatic embryogenesis from hypocotyls and their subsequent development into plants from two important commercial cultivars.

Two popular cultivars of groundnut (*Arachis hypogaea* L. cvs VRI-2 and TMV-7) were used in this investigation. Seeds were removed from the pods and immersed in 100 ml of sterile distilled water with 5 drops of Tween 80 for 5 min. Surface sterilization with 0.1% (W/V) aqueous mercuric chloride for 7–10 min was followed by 5 rinses in sterile distilled water. Seeds were germinated on MS[14] basal medium in culture tubes and kept under dark for germination at 24 ± 2°C. Hypocotyl explants of 7-day-old seedlings were used as the sources of explants.

Eight to ten hypocotyl explants (0.5–1.0 cm length) were cultured in 250 ml conical flasks. The induction medium consisted of MS salts, B5 vitamins[15], 40 g/l sucrose with different concentrations of 2,4-D or NAA (1.0, 5.0, 10, 15, 20, 25 and 30 mg/l) in combination with BAP (0.5 mg/l). The pH of the medium was adjusted to 5.8, 0.5% (W/V) agar was added, and autoclaving was done at 121°C for 15 min. The cultures were incubated for four to six weeks at 24 ± 2°C under cool-white fluorescent light at 40 $\mu E\ m^{-2}\ s^{-1}$ with a 16 h photoperiod. The per cent of embryogenesis was calculated as follows: (Number of explants showing embryogenic calli/Total number of explants cultured) × 100.

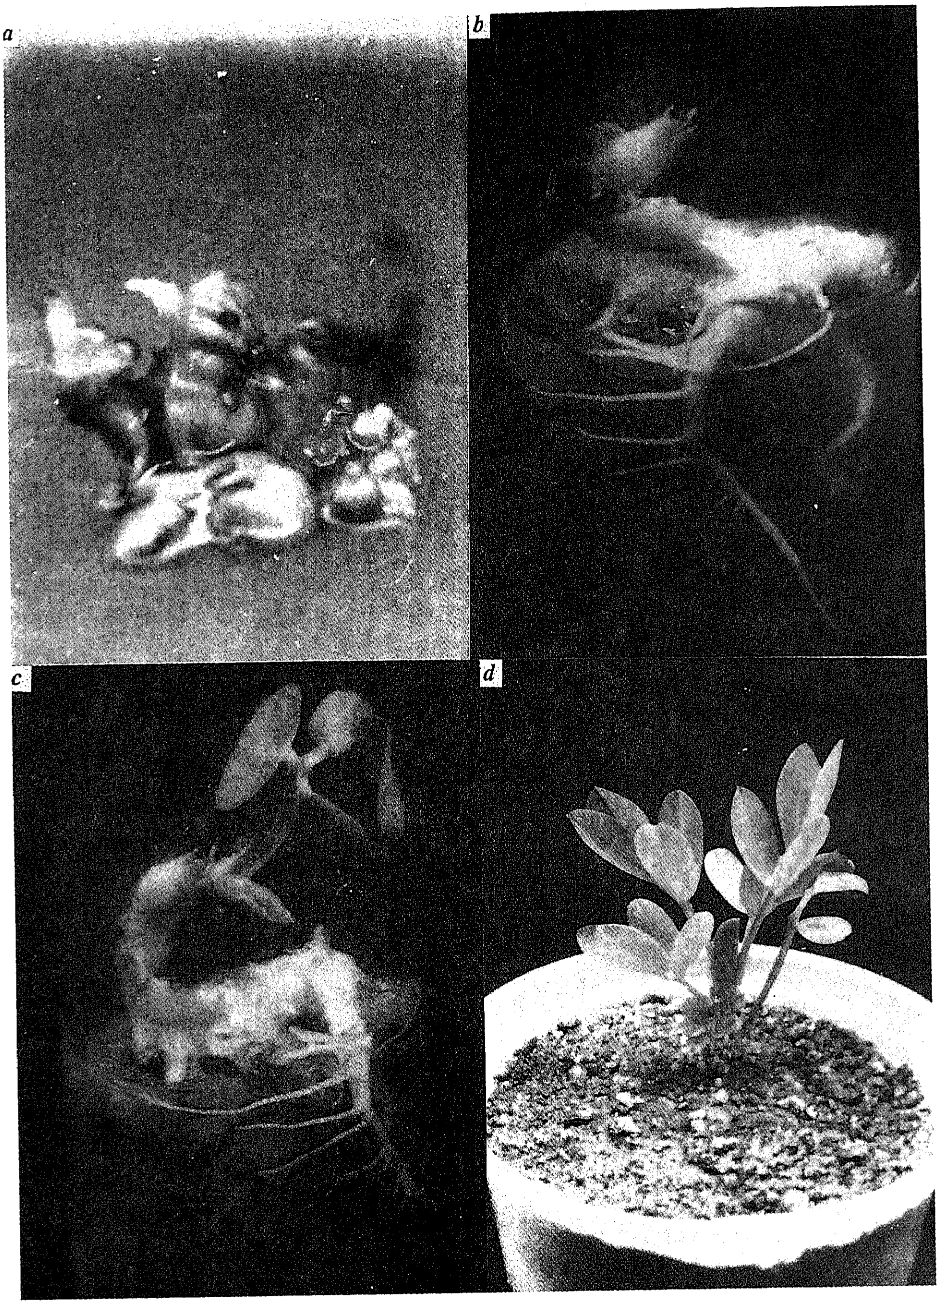

Figure 1 *a–d*. Development of plants through somatic embryogenesis in *Arachis hypogaea*. ***a***, Differentiation of embryos from hypocotyl explant on MS medium supplemented with 20 mg/l 2,4-D and 0.5 mg/l BAP; ***b***, Germination of embryos on MS medium containing BAP (2.0 mg/l) and NAA (0.25 mg/l); ***c***, Plantlet development from somatic embryos; ***d***, Regenerated plant established in plastic cup.

After 5 weeks on induction media, embryogenic mass from the preliminary experiment was transferred to the maturation medium containing 3% (W/V) sucrose, different concentrations of BAP (0.5–2.0 mg/l) and 2,4-D (0.5 mg/l) and solidified with 0.7% (W/V) agar and adjusted to pH 5.8 prior to autoclaving. The cultures were subjected to a photoperiod of 16 h light (40 $\mu Em^{-2} s^{-1}$) and incubated at 24 ± 2°C. The percentage of embryogenic calli with mature embryos was calculated as follows: (Number of embryogenic calli showing mature embryos/Total number of embryogenic calli cultured) × 100.

After reaching the dicotyledonary stage, the embryos were individually transferred to MS medium containing different concentrations of BAP (0.5–2.0 mg/l) in combination with NAA (0.25 mg/l), 2% (W/V) sucrose and 3% (W/V) activated charcoal for germination and conversion into plantlets. The cultures were incubated for two weeks at 24 ± 2°C under cool-white fluorescent light at $40\ \mu E\ m^{-2}\ s^{-1}$ with 16 h photoperiod. The conversion frequency was calculated as follows: (Number of embryos germinated/Total number of embryos cultured) × 100.

Fully germinated embryos were transferred to growth regulator free MS medium with 0.7% (W/V) agar for further elongation of shoots and roots. Cultures were incubated for 10 to 15 days in test tubes with 15 ml medium, under conditions described for germination of somatic embryos. Plants with well-developed roots were transferred to plastic cups containing a 1:1:1 mixture of sand, red soil and manure. Each plantlet was covered with a polyethylene bag and the cups were maintained in controlled temperature at 60% relative humidity. Well established plants from cups were transferred to the field. Regenerated plants were grown to maturity that produced normal flowers and set viable seeds in pods.

Statistical computations were performed using computer software. The cultures were observed periodically and the somatic embryo induction, maturation and germination percentages were recorded on the basis of visual observations. Wherever possible, the effects of different treatments were quantified on the basis of percent cultures showing the response per culture. The experimental design was random and factorial with auxin and cytokinin as independent variables. The data pertaining to percentage of embryo induction, maturation and conversion were subjected to analysis of variance (ANOVA) test. Mean separation was done using Duncan's New Multiple Range Test (DNMRT).

Highly organized, round, creamish to white coloured protuberances differentiated from all over the surface of the hypocotyls when cultured on MS medium containing different concentrations of 2,4-D or NAA (1–30 mg/l) in combination with BAP (0.5 mg/l). The epidermal cell layer of the hypocotyl split up and organized structures emerged from the subepidermal layers. The number of organized structures was higher at the cotyledonary nodal region compared to the rest of the hypocotyl. These organized structures closely resembled globular and heart-shaped somatic embryos (Figure 1 *a*). 2,4-D at a concentration of 20 mg/l produced the highest frequency of cultures showing somatic embryogenesis (62.7%) and highest average number of somatic embryos per hypocotyl explant in VRI-2 which was statistically significant at 1% level (Table 1). However, in cv TMV-7, 20 mg/l of 2,4-D induced the highest frequency of responding cultures (50.3%) and induced the highest number of somatic embryos (Table 1). When NAA was used at 1, 5, 10, 15, 20, 25 and 30 mg/l, the frequency of response varied from 9.2 to 40.5% and 7.2 to 34.2% in VRI-2 and TMV-7 cultivars respectively and average number of somatic embryos per hypocotyl ranged from 3 to 11 and 2 to 9 in VRI-2 and TMV-7 cultivars respectively (Table 1).

Table 1. Frequency of somatic embryos from hypocotyl explants of *Arachis hypogaea* cultured on a medium containing different concentrations of 2,4-D and NAA in combination with 0.5 mg/l of BAP

For further development, globular and heart-shaped somatic embryos obtained from hypocotyls were transferred to MS medium supplemented with 3% (W/V) sucrose, different concentrations of BAP (0.5–2.0 mg/l) in combination with 0.5 mg/l 2.4-D. About 80% of the globular and heart-shaped embryos of both the cultivars developed into torpedo and cotyledonary stages in this medium. The medium without BAP did not promote the growth of the embryos. Such embryo development was observed in all combinations with varying frequencies. The highest frequency of embryo maturation (VRI-2:82.7% and TMV-7:74.3%) was observed on a medium containing 2 mg/l BAP in combination with 0.5 mg/l 2,4-D in both the cultivars, which was highly significant (Table 2). Embryos were very loosely held on the surface of calli and matured synchronously. Maturation increased with the increase in the BAP concentration. After isolation of mature embryos from both cultivars, they were transferred to MS medium containing 2% (W/V) sucrose, different concentrations of BAP (0.5–2.0 mg/l) in combination with NAA (0.25 mg/l) and 0.3% (W/V) activated charcoal for germination. Germination of cotyledonary stage embryos varied with different concentrations of BAP. Germination of embryos was characterized by simultaneous production of root and shoot systems (Figure 1 *b*). Embryos induced from hypocotyls in the presence of 2,4-D or NAA and transferred to germination medium turned green and developed by elongation of hypocotyl revealing the folded cotyledon. Later, cotyledons unfold and the shoot region developed further with the emergence of the first leaves. When MS medium was used with different concentrations of BAP (0.5–2.0 mg/l) in combination with NAA (0.25 mg/l), both shoot and root pole developed in all the combinations with varying frequencies. However, BAP (2.0 mg/l) and NAA (0.25 mg/l) combination was found to be best for highest frequency of embryo germination (VRI-2:81.7% and TMV-7:73.7%) in both the cultivars which was significant at 1% level (Table 3). Thus, BAP was necessary for germination of somatic embryos of the cultivars used in the present investigation. Germinated embryos produced good shoot and root systems when transferred to growth regulator free MS medium (Figure 1 *c*). Germinated embryos developed into complete plantlets on MS basal medium within 2 weeks. Regenerants were successfully transferred to the plastic cup (Figure 1 *d*) and subsequently transferred to the field. Properly hardened plants flowered normally and set viable seeds like that of seed grown plants (controls).

Table 2. Effect of BAP level in combination with 0.5 mg/l 2,4-D on embryo maturation from hypocotyl derived embryogenic calli of two groundnut cultivars

BAP concentration (mg/l)	No. of calli plated		No. of calli showing mature embryos		Embryo maturation response ± SD

Present studies have shown that it is possible to induce somatic embryogenesis and plant regeneration from hypocotyl explants of known commercial groundnut cultivars. Immature cotyledons[6,9], immature leaf[7,8] and immature embryos[11,16] have been successfully used for somatic embryogenesis in groundnut. Plantlet formation remained a problem in conversion of somatic embryos to plants, after transfer to basal medium, (ranged from 0 to 18%) in all the previous experiments[8–10]. In groundnut cultivars, 2,4-D was found to be the auxin of choice for the induction of somatic embryogenesis although NAA was also effective[10,17].

In media supplemented with 2,4-D (1.0–30 mg/l), clusters of somatic embryos developed from the cotyledon part of the adaxial side of the hypocotyl. This was accompanied by callusing. In media containing lower concentrations of NAA (1, 5 mg/l), callusing was observed from the cotyledon part of the hypocotyl without any sign of embryogenesis. However, at higher concentrations (10–30 mg/l), clusters of yellowish green somatic embryos differentiated from the cotyledonary nodal region of hypocotyl. 2,4-D and NAA[8,10,11,14] were widely used for somatic embryo induction in groundnut. Addition of cytokinin (BAP or KIN) to the medium promoted growth, development, maturation and conversion into plants of somatic embryos in culture. Cytokinins are known to enhance shoot morphogenesis. However, when cytokinins were used along with auxin, it showed positive effect on somatic embryogenesis in groundnut[13,16]. Embryogenesis was induced with a frequency of 40.5% with 11 somatic embryos/explant on MS medium containing 20 mg/l NAA and 0.5 mg/l BAP. However, higher concentrations (25 to 30 mg/l) of 2,4-D or NAA in combination with 0.5 mg/l BAP decreased the embryo induction frequency as well as number of somatic embryos/explant. Reddy and Reddy[16] and McKently[18] similarly observed somatic embryos on 2,4-D and BAP containing medium. The effectiveness of an auxin type appears to be tissue and species specific.

In the present study, frequency of embryogenesis and number of embryos per explant decreased with increasing concentrations of auxin level beyond 20 mg/l. McKently[18] found in embryo axis cultures, that as auxin concentrations increased (1–10 mg/l), the probability of obtaining a normal-shaped groundnut somatic embryo decreased. Higher concentrations of auxin not only decreased the embryos/explant but also delayed the embryogenesis[16]. Present studies have shown that conversion of somatic embryos into plants was dependent on the type and concentration of auxin used in the somatic embryo induction medium. The best plant conversion frequency (81.7%) was obtained when 2,4-D was used for somatic embryo induction from hypocotyl. Among the various cultivars studied in India[6,8,10,13] so far and in the present study, somatic embryogenesis seems to be better suited for genetic manipulation studies, because of high frequency of plant conversion, etc. The frequency of somatic embryogenesis in the present study was found to be the result of interaction between genotype and the type and concentration of auxin used. Parrott *et al.*[19] found that the genotype had a significant effect on the ability of immature soybean cotyledons to undergo the auxin-stimulated somatic embryogenesis.

In conclusion, an efficient protocol was developed for high frequency somatic embryogenesis using a simple medium. The present protocol has a distinct advantage over the earlier published protocols, the explant is hypocotyl by germinating seeds, which is available throughout the year.

Influence of metalaxyl on *Glomus fasciculatum* associated with wheat (*Triticum aestivum* L.)

P. K. Shetty and S. P. Magu*

Bioremediation Laboratory, National Institute of Advanced Studies, Indian Institute of Science Campus, Bangalore 560 012, India
*Division of Microbiology, Indian Agricultural Research Institute, New Delhi 110 012, India

Soil incorporation of metalaxyl [methyl *N*-(2-methoxyacetyl)-*N*-(2,6,xylyl)-DL-alaninate] significantly enhanced root colonization of the vesicular–arbuscular (VA) mycorrhizal fungi *Glomus fasciculatum* associated with wheat. The stimulatory response of VA mycorrhizal fungi to low concentration of metalaxyl resulted in increased plant biomass production, nutrient uptake and grain yield of wheat. However, higher concentrations of metalaxyl, particularly 2.5 ppm of metalaxyl affected the mycorrhizal infection and seed yield of wheat. Addition of urban compost to an extent ameliorated the toxic effect of fungicide on VA mycorrhizal colonization, plant growth and yield of wheat when compared to unamended soil.

THE role of agro-chemicals on vesicular–arbuscular mycorrhizal development and efficiency requires better understanding because mycorrhizal fungi are necessary components of most plant systems, and have significant effect on plant growth, physiology and nutrition. Several workers[1–3] have reported the adverse effect of systemic and nonsystemic fungicides to VA mycorrhizae. Recently, considerable attention has been given to a systemic fungicide metalaxyl [methyl *N*-(2-methoxyacetyl)-

N-(2,6,xylyl)-DL alaninate] and its influence on VA mycorrhizal colonization. Metalaxyl is an acylalanine fungicide that controls root rot incited by Oomycetes of the order Peronosporales. Soil incorporation of metalaxyl has been reported to increase VA mycorrhizal colonization in some of the economically important crops[4–6]. The present experiment was carried out to evaluate the effect of different concentrations of metalaxyl on VA mycorrhizal colonization, plant growth and yield of wheat.

Sandy loam soil was collected from an uncropped grassy area of the Indian Agricultural Research Institute farm, New Delhi, and passed through a 2 mm sieve. The preliminary analysis of the soil used showed 0.18% organic carbon, 0.026% total nitrogen, 3.2 kg ha^{-1} available phosphorus, 140 kg ha^{-1} available potash and the pH was 7.2. Metalaxyl was obtained from Ciba-Geigy, Switzerland. The soil was treated with 0.5 ppm, 1.0 ppm and 2.5 ppm of metalaxyl prior to sowing. Soil amendment was done with 1% urban compost to mitigate the deleterious effect of fungicide. Urban compost was obtained from the mechanical compost plant, Okhla, Delhi. The proximate analysis of urban compost is given as follows: Organic carbon 16.86%, total nitrogen 0.42%, available phosphorus 0.037%, water holding capacity 82.73% and the pH 8.10.

Seeds of wheat (*Triticum aestivum* L.) cultivar HD-2428 and culture of VA-mycorrhizae *Glomus fasciculatum* were obtained from the Cereal Laboratory and the Division of Microbiology, IARI, New Delhi, respectively. Plants were grown in earthen pots (13″ × 12″) containing 10 kg of ground and sieved soil. Undamaged, healthy and uniform seeds were surface sterilized by rinsing in 95% ethanol in a clean sterile beaker for one min, followed by immersion in 0.2% acidified $HgCl_2$ for 5 min and washed in several changes of sterile distilled water.

The VA mycorrhizal fungus was inoculated by the layering method[7]. The inoculum consisting of ground and dried sand: soil mixture containing infected root segments and chalamydospores were used at the rate of 100 g pot^{-1}. The inoculum was placed in layers or pads at a depth of 3.5 cm from the top, over which a thin layer of soil was spread. Holes were made to dibble the seeds. Before dibbling the seeds, small quantity of VA mycorrhizal inoculum was added beneath the seeds so as to enable the inoculum to come in contact with emerging roots. The plants were watered on alternate days to near-field capacity. Inoculated controls were maintained without fungicide. The plants were harvested after 40, 80 and 120 days of growth. At each harvest, per cent mycorrizal infection, dry weight of shoots and roots were recorded and the representative samples were analysed for N and P. The concentration of P was estimated by the vanadomolybdate method after digestion with tri acid mixture. Similarly, the nitrogen content was determined by the kjeldahl method[8]. After harvesting, part of the root system was cleared and stained[9] and the per cent mycorrhizal colonization was assessed and calculated from the frequency distribution method[10].

The present investigation revealed that low concentration of metalaxyl resulted in an increased mycorrhizal colonization of wheat roots at all the stages of observation (Table 1). Previous studies reported[5,11] that use of metalaxyl at recommended field rates either increased or had no adverse effect on mycorrhizal colonization associated with maize and sorghum respectively. Though the precise mechanisms by which the fungicide stimulates the VA mycorrhizal fungi are unknown[12], probably

Table 3. Effect of metalaxyl on grain yield, nitrogen and phosphorus[3] uptake (g plant^{-1}) at harvesting stage of wheat

metalaxyl enhances the VA mycorrhizal infection by reducing the population of plant pathogens and also other soil microbes which are responsible for suppression of root colonization, thus allowing greater invasion of roots by VA mycorrhizal fungi[13,14].

The stimulatory response of VA mycorrhizal fungi to low concentration of metalaxyl resulted in the increase in biomass (Table 2), nutrient uptake and grain yield of wheat (Table 3). Similarly Afek *et al.*[15] observed an increased VA mycorrhizal colonization of roots and plant biomass in the presence of metalaxyl. The primary mechanism which is responsible for stimulation of plant growth by VA mycorrhizal fungi is due to increased uptake of phosphorus and other nutrients. The possibility of plant growth harmones being involved in such a response has also been suggested[16]. Further, Barea and Azcon-aguilar[17] observed the substances with the properties of gibberellic acid and cytokinin in the extract of *Glomus mosseae* culture.

The reduction of VA mycorrhizal infection and plant growth at higher level of metalaxyl were attributed to suppression of the mycorrhizal fungus by the fungicide. Jabaji Hare and Kendrick[12] have reported the inhibition of mycorrhizal colonization of leek roots by metalaxyl and also the fungicide significantly decreased growth of plants with time. The effect of metalaxyl on mycorrhizal infection may be a direct action or mediated through phytotoxic effect on root function and growth. In an experiment[18], application of metalaxyl at a rate of 200 μl/l reduced the plant biomass of prairie grass in steamed and nonsterile soils, the results indicated that higher level of fungicide application was phytotoxic. It was observed that the amendment of one per cent urban compost to an extent ameliorated the toxic effect of metalaxyl on VA mycorrhizal infection, plant growth, nutrient uptake and yield of wheat when compared to unamended soils. Schiavon *et al.*[19] and Stearman *et al.*[20] reported that organic matter reduces the phytotoxicity of agro-chemicals, whereas fulvic acid and humin helps in detoxification through formation of low energy bonds. Further, organic matter provides more sites for adsorption to the pesticides, thus reducing its amount in soil solution and protecting microorganisms from the toxic effects.

QED: The Jewel of Physics. G. Venkataraman. Universities Press, 3–5–820, Hyderguda, Hyderabad 500 029. 1994. 133+viii pp. Price: Rs 65.

Eugene Wigner delivered a lecture in 1960, 'The unreasonable effectiveness of mathematics in the physical sciences'. Since then, this happy phrase has resounded through the literature of the exact sciences as the laying down by the physical scientist of the articles of his creed. For all this, mathematics has shown itself on occasion to be an unreliable ally, demonstrating a perverse willingness to comprehensively wreck the most elaborately constructed theory. And one of the most shocking instances of the breakdown of this *entente cordiale* in this century occurred during the development of quantum mechanics. To set the scene briefly, in 1933 Dirac's landmark paper had appeared, in which he initiated the second stage in the development of quantum theory by quantizing the electromagnetic field of Maxwell; and its relativistic version followed shortly thereafter. But no sooner had the new theory been erected, than it promptly loosed a 'plague of infinities' on its hapless creators. In this book under review, the second of his three-part history of quantum theory, Venkataraman takes up the story at this point and follows it to the late forties, when sanity was restored to the theory to the extent where it at least allowed a functional facility with calculations, by exorcising the infinities from it. It is also the story of three extraordinary physicists and their diverse personalities, who in large part were personally responsible for restoring quantum mechanics to its state of grace.

The book opens with a summing up of the topics treated in the first part, 'The breakthrough'. The rehash is occasionally seasoned with some of the more exotic spices of physics' larder. There is for instance, Feynman's theory of the electron moving back in time. (As in the earlier volume, Feynman's spirit animates the present one, stalking through it as a ubiquitous presence. In actuality, he may have been one of the three men who had cut quantum theory's Gordian knot. But Feynman's stature has grown through legend in popular imagination, till the exuberant vitality of his genius has been allowed to preside with the magisterial dignity of an elder statesman over the whole of quantum electrodynamics.) This introductory chapter – rather surprisingly a fifth of the book in length – begins with a discussion of the expression for the energy of an electromagnetic field. This expression is transformed into an equivalent form (by minding one's p's and q's, literally) in which it is analogous to the Hamiltonian of a one-dimensional oscillator. Apropos this procedure, it has to be remarked that here, as elsewhere, the author appears understandably defensive about importing some high voltage mathematics into the text – the inevitable occupational hazard of an undertaking like the present one, which aims at a level roughly between a popularization and a textbook. Thus, with a quick apologetical murmur about 'a bit of algebra', the end result is produced (page 4) with the air of a conjuror materializing a rabbit out of a top hat. (One is irresistibly reminded of the eponymous hero of Salman Rushdie's *Haroun and the Sea of Stories*, who, when asked for a clarification, disarmingly confesses it to be a P2C2E – a process too complicated to explain!)

A similar observation could perhaps be made about a cascade of undefined terms – e.g. relativistic covariance, energy of a radiation field, coupling energy, zero point energy, etc. – in the opening chapter itself. While on the subject, it has to be pointed out that if there is an Occam's Razor for writers, it would surely admonish aspiring authors not to proliferate jargon beyond strict necessity. For instance, it does not add anything to a reader's enlightenment that the symbol A (in page 7) is called the vector potential of a magnetic field. To paraphrase the little girl who was immortalized for her adventures in Wonderland, that is rather a lot for a symbol to mean.

The second chapter introduces the Feynman diagrams – the technique that Feynman invented to understand the mechanism of particle interactions. These schema constitute Feynman's abiding contribution to the language of modern theoretical physics. A large part of this chapter is devoted to developing familiarity with manipulating these diagrams and extracting information from them. The ideas are set out with all the beautiful clarity, which is the hallmark of Venkataraman's writing. This is in spite of a few minor lapses – the diagram 2.2 for instance, has been wrongly labelled. Finally, near the end of the chapter, we are shown the mathematical sleight-of-hand by which Schwinger, Feynman and Tomonaga tamed the infinities that the Dirac equation had unleashed.

The following short chapter presents the three pieces of evidence which clinched the issue in favour of QED and launched it into its career as the most successful scientific theory of all times – the Lamb's shift in hydrogen, the anomalous magnetic moment of the electron and the splitting of the ground state of positronium. But what features of the new theory ensured this resounding success? In the fourth and longest chapter of the book, Venkataraman takes up this question and shows that strict conformity at every stage with the requirements of relativity was the crucial ingredient of the new recipe. In Oppenheimer's perception, 'not merely the field equations themselves, but the whole method of approximation and solution must at all stages preserve relativistic covariance'. A review of the theory of path integrals and renormalizability concludes the chapter. One reflection on the use of equations in this book – Stephen Hawking's publisher reportedly advised him that with every equation he introduced into his book, he was halving his potential audience. One rather sees his point when one comes across instances of equations like,

$$\psi(t) = \psi(t_0) - (i/h)\int_{t_0}^{t} \psi(t')\, H_I(t')\mathrm{d}t',$$

(in page 69) which are mere shotgun marriages of the left and right hand sides performed by the equality symbol as the officiating priest. There are perhaps inevitable constraints when advanced scientific theories are discussed at popular levels of exposition. Unfortunately, the arduousness of such an undertaking cannot absolve Venkataraman from the more serious lapse of using quotations without giving references – rather disconcertingly like plucking apples from an invisible tree.

At this stage, much like an alpine guide pausing to point out features of local interest to a tourist group while waiting for the stragglers to catch up (and the reviewer must confess himself to be of this company), the author breaks the narrative with a biographical interlude of the three architects of QED. Incidentally, for anyone interested in the Feynman story, James Gleick's *Genius* must be mandatory reading – as much for the portrait of the whimsical genius of one of the most extraordinary scientists of all times as for the wealth of its anecdotal detail. In the final quarter of the book, some historical and biographical footnotes bring to a close this excellent account. It is a presentation written with a vigour and verve which do justice to one of the most turbulent epochs in theoretical physics. And, in this as in his other books, Venkataraman has established and maintained a high level of professional rigour in a field which has remained largely neglected in this country.

And what are we to say of QED? Richard Feynman was as clear in his assessment of it as he was in its affirmation, when he called it 'the jewel of physics'. But philosophically, he was an operationalist to whom the quintessence of science resided in its predictive capability. And if he could find an equation which could do just that, he would not concern himself with ontological enquiries into the nature of physical reality – an attitude entirely consonant with an age which had derived its philosophical orientation from logical positivism and the Copenhagen Interpretation. Dirac, on the other hand, died believing that the problems raised by self energy had merely been papered over by a theory cobbled together to permit computational facility. In the final analysis, it must be clear that the last word has not been said about the quantum. A cheerful acceptance of inevitable ignorance might perhaps not be a bad attitude with which to ride out this age of uncertainty – rather like old Kaspar in Southey's *Battle of Blenheim*.

> 'But what good came of it at last'
> Quoth little Peterkin.
> 'Why, that I cannot tell', said he,
> 'But, 'twas a famous victory'.

Banking on Biodiversity: Report on the Regional Consultation on Biodiversity Assessment in the Hindu Kush–Himalayas. Pei Shengji, ed. International Centre for Integrated Mountain Development, Kathmandu, Nepal. Price not known.

Managing biodiversity is managing contradictions. This is more so in frontier areas where international issues become additional problems. At the same time, knowing the fact that the more mobile components of biodiversity do not respect political boundaries, it is necessary for the nations to cooperate if at all they want to see success in the conservation of biodiversity especially in the border areas. Viewed from this perspective, this book is a timely contribution to society.

This book is the outcome of a workshop, on the assessment, monitoring, and management of the biodiversity of the Hindu Kush–Himalayas (HKH) region, that was organized by International Centre for Integrated Mountain Development (ICIMOD) in December 1995 at Kathmandu, Nepal. Experts from eight HKH countries, namely, Afghanistan, Bangladesh, Bhutan, China, India, Myanmar, Nepal, and Pakistan participated. The participants reviewed the status of biodiversity in the region and made recommendations about future plans of actions for each country.

The book is organized into three parts. The first part spells out the proceedings of the workshop and working groups' reports on the issues and needs of biodiversity management in the HKH region, the second contains the country review papers from experts of eight HKH countries and the third contains seminar papers from experts representing international organizations engaged in biodiversity conservation. The book also contains 26 beautiful colour photographs of wildlife.

The title of the book gives a mistaken impression that it contains information about the biodiversity of those HKH regions on which people rely for their future, while the contributors, in their respective country reports, talk about more than what is present in HKH regions of their respective countries. This extra information is welcome in the sense that it informs us about what we have and what we do not. The country reports give an overall review of the current state of biodiversity in the respective countries.

The HKH region is ecologically highly diverse as it covers polar-like environments and cold deserts to the rainforests. Mountain regions are rich in biodiversity because of their inherent environmental heterogeneity. At the same time, they are fragile and prone to degradation due to disturbances. Most of the country reports emphasize this fact. However, a limited human intervention enriches the biodiversity of the mountain regions also.

This book will be useful for biogeographers, policy makers, environmentalists, nature enthusiasts, soldiers of the green brigade, teachers and environmental awareness generators. Initially it looks less useful for the technical professionals who like to go deep into the functioning and processes of nature and then devise measures for the better functioning of the system. However, any technical advice will have to be implemented taking into consideration the other ground realities of the system. A number of such points and issues have been discussed well in this book. Experiences based on the effect of Afghan war on biodiversity and its conservation, importance of predators in rodent (pest) control in Afghanistan, effect of deteriorating law and order and erosion in the sense of value in Bangladesh, emphasis on maintenance of essential ecological processes, and the work of international organizations like WWF, IUCN, IBPGR (now IPGRI) in various countries in conserving biodiversity, could prove useful for technical professionals.

The quality of write-up, information given and the presentation from various contributors to the book are indicators of the technical know-how, scientific capabilities and the work already done in various HKH countries. China and India have done relatively well in this regard and have vision and future plans like undertaking integrated regionalization of biota, replanning of nature reserves on the basis of the regionalization and overall regional considerations. Small countries also have success stories and experiences of all sorts that will be very useful to the policy makers and the researchers. Most of the countries have emphasized studies on species of economic importance and their wild relatives. Simultaneously, the HKH region has a number of botanical curiosities to offer to us.

In most of the HKH countries the earlier plant explorers were the westerners and at present also there is shortage of taxonomic expertise in these countries mainly because of lack of funds, motivation and mismanagement. Examples of the experiences of small countries include the success of the great one-horned rhinoceros in Royal Chitwan National Park in Nepal, and wildlife conservation in the Bar Valley with the help of locals in Pakistan. However, the author (contributor) from Pakistan seemed to be better experienced about the factors causing loss of biodiversity. He was even suspicious about the process of economic development itself which, he thinks, could widen the inequality and force the poor to depend more on natural resources. Pakistan's experience, of the effects of the Afghan war on its biodiversity in the regions where Afghan refugees came, the effect of the hunting culture of Mughal emperors and the hangover of this culture (a number of its wild animals hunted to local extinction), could be seen in the book. A number of other factors like low literacy, absence of respect for law, lack of political commitment and environmental awareness, etc. have added to such local extinctions. Such local extinctions would add to global extinctions about which all conservationists should worry.

The seminar paper by Busby and Gordon on biodiversity information management and their call for information cooperative not only makes very good reading but also seems to be a very good idea. However, only time will tell whether such enlightened people really want to conserve biodiversity with the intention of empowering the custodians of biodiversity or want to seek monopoly on whatever is left with others. Conservation issues are quite complicated and depend on many factors. That is why there are situations when legislations convert forest use from necessity to crime. The book brings out such inherent contradictions in conservation issues. The editor and the contributors deserve hearty congratulation for their effort in educating us.

IUCAA revisited

In September 1990, I had visited the Inter-University Centre for Astronomy and Astrophysics (IUCAA) when it was in the process of being set up as a resource centre for Astronomy and Astrophysics (A&A) in the university sector. The idea of setting up such a centre in the pleasant surroundings of the campus of the University of Pune was inspired by another major project in astronomy also being based there: the Giant Metrewave Radio Telescope of the Tata Institute of Fundamental Research.

Indeed, during this first visit, the wing of the TIFR managing the GMRT project (now named the National Centre for Radio Astrophysics) already had its buildings and, being next door to the up and coming IUCAA, had lent the latter its facilities. Thus the seminar which I went to attend was in fact held in the lecture hall of the NCRA. I recall being taken round the IUCAA site by its Director, Jayant Vishnu Narlikar who not only briefed me on the mandate of the budding inter-university centre, but also on how the buildings were being planned to achieve its aims and objectives.

To me it seemed a far extrapolation from the few activities which I saw, managed by a skeleton staff, to the full fledged institutional programme as envisaged in the ambitious project report written in 1988, the year the centre was founded. It was yet another extrapolation, from the chaos and bustle of the building construction then going on to the architectural masterpiece which was envisioned. I recall leaving for Bangalore with good wishes for this new experiment in the university sector, but also apprehensions as to its success.

A few months ago I had a chance of a second visit, now after a span of some six years. How do the vision and dreams compare with achievement and reality?

Campus

No visitor to this beautiful campus can deny that it is indeed a unique piece of architecture, where the imaginative use of spaces to promote mixing and interactions between the scientist users goes hand in hand with well-planned interiors, soothing landscaping and last but not the least, careful attention towards maintenance. A marked contrast to so many of our public institutions which are inaugurated with great fanfare but begin to decay from day one for lack of attention to such details. The director gave full credit to the architect and the various consultants and to his own colleagues for all this.

The IUCAA buildings are spread over three plots divided by two roads named after Meghnad Saha and Vainu Bappu, two Indian stalwarts in A&A. Akashganga has the staff colony and the recreation centre, Devayani houses the main office buildings and facilities of the Centre while Aditi has the Chandrasekhar auditorium and of course, the shed Aditi where the IUCAA had started its activities in 1989. The different blocks in Devayani are named after Indian astronomers of an earlier age, Aryabhata, Varahamihira, Brahmagupta and Bhaskara (see *Curr. Sci.*, 1990, **59**, 962–964).

While going round these blocks, I came across one named 'Ballava'. Who was Ballava, I asked. Jayant explained that it was the name assumed by Bhima when he went incognito in the court of Virata in the Mahabharata saga, when he played the part of the chef in the royal house. Aptly the name is given to the IUCAA canteen block! Inside the canteen one sees a sobering quotation which would bring any astronomy researcher back to earth: The discovery of a new dish does more for human happiness than the discovery of a star. Predictably, the quotation is from Brilliant-Savarin, a great chef.

Exhibits

A speciality of the campus is the integration of the architecture with scientific exhibits. Thus the centrepiece of Devayani is the Kund which has four statues, of Aryabhata, Galileo, Newton and Einstein. Behind Aryabhata, appropriately, is the entrance to the Aryabhata block with the centrepiece of the Foucault Pendulum. In his shloka in *Aryabhatiya*, Aryabhata had stated that the Earth spins about an axis and hence the fixed stars appear to move in the westerly direction. The Foucault pendulum reminds astronomers that the Earth's spin relative to an inertial frame can be measured without recourse to the stars. Newton's statue has an apple sapling specially gifted by the Brogdale Horticultural Trust: it is a plant whose ancestry can be traced to the orchard in Newton's home, the Woolsthorpe Manor.

At the centre of the Kund itself is a representation of what radio astronomers would identify as a radio source with accretion disc and jets coming out of the central compact region.

The guest house cum hostel is called Nalanda and its courtyard has the Sierpinski gasket landscaped. . . a fractal figure of Hausdorff dimension 1.58 approximately. The smallest of the three principal courtyards has two banyan trees which symbolize a binary star system whose Roche lobes and Lagrangian points are well identified.

Across the Meghnad Saha road, within the foyer of the auditorium is the aperiodic tiling whose mathematical features were highlighted in Roger Penrose's book *The Emperor's New Mind*. Under construction outside is a replica of the Hampton Court Maze whose walls are made of hedges. It is an excellent practical exercise in the connectivity of figures. Indeed there are plans to develop the outside areas into a science park. A replica of the Samrat Yantra already dominates this area.

The astronomical pictures gifted by David Malin adorn the walls on the first floor of Aryabhata while Ashwin Mehta's photographs grace the ground floor. There are the occasional wall paintings like the Lorentz attractor and Glashow's snake to which more may be added in due course.

Facilities

The IUCAA was designed to provide facilities to university academics which will help raise their productivity in A&A both in quality and quantity and provide them with new avenues of research. The excellent library, computer centre with worldwide access on the networks, the data centre which can tap on-line databases, the instrumentation laboratory which provides opportunities and guidance in do-it-yourself instrumentation in the astronomical field are housed in the north-east corner of the Devayani compound, around the smallest of the three courtyards.

The visitors need housing which is provided in the Nalanda Guest House and the Takshashila apartments. University faculty and students, participants of workshops and training programmes as well as experts from outside are housed here. With a commuting distance of less than a hundred metres to work, and the fact that academic work can go on in principle at any time of the day or night, the visitors should have no cause for complaint!

Programmes

In the project report, the IUCAA had projected its activities along an 'eight-fold way', involving simultaneous attacks on several fronts. Even when I had first visited, these activities were initiated despite small and inadequate infrastructure. IUCAA's academic calendar is published around June every year and it makes impressive reading. Apart from its own inhouse graduate school, the IUCAA faculty are guest lecturers in the astrophysics M Sc stream of the Pune University Physics Department. There are a number of schools and workshops throughout the year, ranging from the introductory to the frontier level both at the IUCAA campus and in different universities.

Thanks to its guest observing programme, IUCAA has been able to involve university academics in optical astronomy in India and abroad. Encouraged by the response and anticipating growth in the coming years, a 2-metre class telescope has been ordered with the Royal Greenwich Observatory, UK and it should be operational well before the end of this century.

The IUCAA has been getting more and more university departments interested in including A&A as a special subject in the Physics or Mathematics M Sc programmes. Thus a model syllabus has been framed in a modular form which can be adapted to the system prevailing in any particular university.

The culture of instrumentation has been catching up, thanks to the projects initiated by the instrumentation laboratory. I saw a prototype 14-inch automated photoelectric telescope being fabricated. It is being duplicated by a team from Bangalore University. Hopefully, other universities will follow this example.

There are other smaller projects relating to detectors. There are more ambitious proposals for sophisticated instruments to go with the IUCAA telescope. It is hoped that the universities will be involved along with IUCAA in these.

As a part of efforts to mobilize human resources in A&A, science popularization forms an important programme of IUCAA. In 1991, IUCAA convened a national meet of amateur astronomers. This proved to be a catalytic activity which set the pattern for future such meets convened annually in different parts of the country. Now the amateurs have formed a national confederation of different clubs. In addition, workshops for making telescopes and sky globes by IUCAA have proved popular.

An important feature of all such programmes is IUCAA's involvement with school children through lectures and summer projects. The lecture demonstrations in English, Marathi and Hindi in the IUCAA's Chandrasekhar auditorium on the second Saturday of the month are oversubscribed. In the summer vacations, over 100 children from Pune schools spend a week each at IUCAA doing some astronomy-related project with a staff member. From research students to the director, all members participate in this programme actively.

Achievements

Thus great care has gone into the planning and management of this centre and its academic programmes. This brings me to the basic question: Has the idea of such a centre worked? Are the aims and objectives of the centre given in the project report being fulfilled? There is no doubt that the work done at IUCAA is already beginning to be known internationally. The response to IUCAA's post-doctoral programme, the participation of its academics in its international programmes and conferences, and the flow of reputed scientists to the centre's academic activities have all been very encouraging.

But how about its impact on the university scene? Here the achievements have been admittedly mixed. The general feeling was that the associateship programme has helped uplift the work of some twenty per cent of the participants, while for another twenty per cent the improvement may show in another three to four years. Why are these percentages low? The reasons are many.

The university system has its own inertia. Despite exhortations to the vice-chancellors by the successive Chairpersons of the University Grants Commission to look upon the Inter-University Centres as their own field stations, very few have been liberal enough to grant suitable leave facilities to the associates to enable them to come and visit IUCAA for their work. The numerous workshops and schools do help introduce new research topics to academics from the universities, but only a percentage of the above order have taken advantage of them. Perhaps IUCAA needs to adopt a more agressive and persuasive technique to bring about changes of attitudes.

The new project of the IUCAA telescope has great potential for encouraging the observational programmes amongst universities. There will be practical difficulties like the observer getting leave at the time when his or her programme is scheduled, the paucity of student-power in the universities, etc. These are challenges to be met.

Even before the completion of the GMRT project, a community of university users in radio astronomy has to be built up. Perhaps it is time for IUCAA and the NCRA to get together to formulate a strategy that will gradually induct the universities into using the GMRT.

What of the future?

Having visited the Inter Universtiy Consortium for DAE facilities (IUC-DAEF) some years ago (*Curr. Sci.*, 1995, **68**, 670–671), one could not help asking the same questions which came up in the context of that institution. A balance has to be struck between the service activities which form the primary mandate of the institution, and the quality of research by its own scientists. If the latter suffers, then it does affect the wider goal of quality work in

A&A at the universities. My own impression, which seems to agree with that of IUCAA's Director, is that the interaction with universities has been quantitatively as planned but its quality needs to be looked into – easier said than done. Looking at the impressive calendar, one does wonder whether there is a risk of spreading oneself too thin. In the early years, the activities were somewhat top-heavy (i.e. relativity and theoretical cosmology were over-represented), and even after later expansion into other areas, one wonders whether the observational, phenomenological and instrumentational sides of astronomy are fully taken care of. Of course, one could consciously stay away from them, since there are other astronomical institutions in the country, and in fact that would be better than some sub-critical activity for the sake of maintaining a presence.

Having congratulated IUCAA for its rapid progress in the last seven years, I may be forgiven some cautionary remarks, based on my experience with at least four institutions. The initial years are in some sense a honeymoon period, when novelty and excitement act to mask the precursors of the troubles ahead. A wise institution (or couple!) would do well to anticipate some of these. Scientists are by their very nature individualists and hard to weld into a team. In fact, the problem of getting faculty to pull together and respect and take part in collective decision making is widespread. The alternative, of relying on the energy, initiative, and judgment of a single personality, does not work forever! Given the overall goal of helping the university sector, some guidelines have to be laid down and followed, so that the burden of this task does not fall on too few shoulders. One must say that by and large, the structure and functioning of IUCAA have a degree of transparency which is rare elsewhere in the country.

Ultimately, the relation of IUCAA and the Universities has to evolve to become an equal one, based on mutual respect, rather than mutual need. One knows that the world's best radio telescopes, run by the National Radio Astronomy Observatory (NRAO) in the USA, come under an organization called Association of Universities for Research in Astronomy (AURA) which is no mere figurehead, but takes a lively interest and role in the functioning of the NRAO. The dilemma of both IUCAA and IUC-DAEF is that at the moment, such inspired guidance from the universities will not be forthcoming and they will have to play the role of a guide to their own future masters. Lest such terminology seem repugnant, let us remember that Jawaharlal Nehru described himself as 'the first servant of the Indian people'. Everyone will wish IUCAA success in the difficult role that it has taken up, of being the first servant of Astronomy and Astrophysics in the Indian Universities.

MINISTRY OF SCIENCE AND TECHNOLOGY
DEPARTMENT OF SCIENCE AND TECHNOLOGY

JSPS POSTDOCTORAL FELLOWSHIPS: 1997–98

The dates for requesting application forms and for their submission have been revised as follows:

Last date for receiving requests: 15 March 1997
Last date for receiving completed application forms: 15 April 1997

MEETINGS/SYMPOSIA/SEMINARS

National Workshop on Technology Management

Date: 5–6 March 1997
Place: Pune

Objectives: To encourage industry–institute partnership programme, Integration of business, technological and strategic management, Study and evaluate the temper and tempo of corporate groups after post-liberalization phase, Evolve industry–institute consensus on various emerging issues, Identification of thrust areas for joint programmes of research and development between industries and institutes.

Contact: Director
Bharati Vidyapeeth's Institute of Management and Enterpreneurship Development
Erandwane, Pune 411 038
Phone/Fax (0212) 331060

Training Programmes in Food Processing

Place: Mysore

The Central Food Technological Research Institute, Mysore is conducting residential courses on 1. Analysis of pesticide residues in foods (10.3.97–14.3.97), 2. Strain improvement of industrial microorganism mutation, protoplast fusion and recombinant DNA (24.3.97–4.4.97), 3. Oilseed processing with an emphasis on indigenous technology (7.4.97–11.4.97) and 4. Flexible packaging of fresh and processed foods (12.5.97–16.5.97).

Contact: Head, Human Resource Development Dept.
Central Food Technological Research Institute
Mysore 570 013.

Workshop on Swift Heavy Ions in Materials Science (SHIMS)

Date: 10–11 March 1997
Place: Bangalore

Topics include: High energy ions in semiconductor devices, Columnar defects in high T_c superconductors and other materials, Thin films, surfaces and interfaces – role of swift heavy ions, HIBS, ERDA, NRA – Nuclear techniques with SHI, Biomaterials, Materials modification with SHI: Polymers, Quasi-crystals, etc.

Contact: Dr D. K. Avasthi
Nuclear Science Centre, New Delhi
Fax: 011–689–3666
E-mail: info@nsc.ernet.in.

National Symposium on Herbal Medicine: Application of Biotechnology and Futuristic Approach

Date: 27–29 March 1997
Place: Dehradun

Objectives: to redefine the term herbal medicine, to create further awareness about herbal medication, to exploit herbal knowledge at industrial scale, to improve and standardize active constituents by use of biotechnology, to expedite research for designing of new medicines.

Contact: Dr Anil Kumar Puniya
Convenor, Department of Microbiology

Ph D Programme in Astrophysics 1997–98

The National Centre for Radio Astrophysics (NCRA) offers opportunities for front-line research in Radio Astronomy and Astrophysics. It operates the large cylindrical radio telescope at Ooty and is currently building the Giant Metrewave Radio Telescope (GMRT) near Pune, which is almost operational. GMRT consists of 30 parabolic dishes, each of 45 metre diameter placed over a region of 25 km, and will be the world's largest radio telescope operating at metre wavelengths.

Areas of research at NCRA include studies of observational cosmology, quasars, radio galaxies, nearby galaxies, interstellar medium, pulsars, stars, solar system as well as techniques of synthesis imaging and image processing. Research scholars will be selected on the basis of a written test and interviews which will be conducted jointly with the Inter University Centre for Astronomy and Astrophysics (IUCAA) in early July 1997 in Pune. Selected candidates will receive Physics and Astronomy courses during the first year as a part of the Graduate School requirements. Satisfactory completion of the Graduate School is required before registration for a Ph D degree at University of Pune. Outstanding students may be absorbed as regular staff of NCRA after their Ph D.

Eligibility: First class in M Sc (Physics/Astronomy)/B E/B Tech (Electronics/Computer Science), with a strong background and interest in Physics. Candidates expecting to obtain their degree by July 1997 may also apply. Candidates with a motivation to pursue experimental research are particularly encouraged to apply.

Financial assistance: Research scholars will be paid a monthly honorarium of Rs 2,700/- which may be raised to Rs 3,000/- after the registration for Ph D. There is an annual contingency educational grant of Rs 7,500/- tenable up to 5 years. Based on periodic reviews, scholarships are renewed annually up to 5 years.

How to apply: Application forms for admission as Research Scholars can be obtained by writing to **Administrative Officer, NCRA-TIFR, Post Bag No. 3, Ganeshkhind, Pune 411 007**, along with a 24 cm × 11 cm stamped (Rs 2.0), self-addressed envelope. The last dates for receiving the request for application form and the completed application are **March 25, 1997** and **April 15, 1997**, respectively. The candidates appearing for the written test and interview will be paid 1.33 times train fare each way by ordinary sleeper class and Rs 75/- per day as halting allowance for the days of the interviews.

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine. G., in *Biology of Bats* (ed. Wimsatt. W. A), Academic Press, New York. 1970. vol 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

Life in extreme environments

Ever since the evolution of early plants about 100 million years ago (during Cretaceous), angiosperms have been invading all the habitats of the planet. They are found almost everywhere including in the Arctic, plains, deserts, swamps, freshwater rapids, salt marshes. However, not all these places can be considered habitable. Many of the environs (such as hot springs, salt marshes and deserts) constitute conditions that at best can only stifle life. But even under these conditions, plants seem to have done extremely well in evolving features of infinite complexity to adopt to the rigors of the environment, making their stay a comfortable one.

Each of the adaptations to the extremes of the environment is a story in a scientific precision and is best exemplified by plants growing in the arid deserts. For example, on a warm summer day, it is estimated that a date palm loses nearly 4000 l of water, a ragweed about 8 l and the common cactus just a couple of spoons of water. Yet all the three systems share the same basic mechanism of uptake of water. The saguaro, one of the remarkable cacti of the Sonoran desert, is believed to store about a ton of water in its stem. A single rye plant, in an attempt to locate water, puts out roots where total length in four months equals the distance between Bangalore and Madras (a promise for cellular phone facility?).

Plants growing in water (e.g. deep-water rice) are known to employ an ingenious technique for transporting oxygen from their leaves to their roots. Many species of plants nonchalantly take to salt-rich diet and thrive exceedingly well in brackish waters and salt marshes. They have elaborate machanisms to 'excrete' the excess salt through their foliage and also compartmentalize salts in their cell vacuole. Plants growing in acid soils readily extrude out calcium salts as a mechanism to neutralize the pH. The list of such adaptations seems to be unending as newer research comes to light. Indeed many of the adversities in the habitat of plants have provided a fair share of excitement to scientists to unravel the underlying mechanisms contributing to the adaptations.

In their article on **page 306**, Mohan Ram and Gupta provide a fascinating account of the natural history of plant life under extreme environment and provoke frequently the necessity to understand the mechanisms contributing to their adaptations.

R. Uma Shaanker

Thyroid hormones

Thyroid hormones and their actions have commanded a separate identity in endocrine literature particularly from a comparative endocrinology perspective. Along with glucocorticoides and pituitary prolactin they are considered 'permissive hormones'. A molecular correlate of 'permissiveness' has eluded researchers in this area. A uniform biochemical correlate applicable to all phylogenic groups has not been established yet.

In the case of warm-blooded animals capable of maintaining constant internal body temperature against external temperature variations (of course within a range and for a certain period of time), regulation of basal metabolic rate (as measured by tissue respiration) by thyroid hormones has been an accepted paradigm for thyroid hormone action. Their calorigenic action is well established. However, such an 'action paradigm' for thyroid hormones in the case of poikilotherms has been difficult to establish. Further, the diverse nature of their effects even within mammals has also created confusion in literature in early periods of endocrinology with regard to their classification into groups labelled as metabolic hormones and developmental hormones. They do bring about predominantly metabolic effects in mammals but their cognate receptors have been localized in nuclei of target tissue cells. This is similar to those of steroid hormones which are clearly classified as developmental hormones. Fittingly, thyroid hormones do have a role in brain development and severe thyroid deficiency leading to growth retardation is an established fact. Further, thyroid hormone T_4 has been long back established as capable of accelerating amphibian metamorphosis.

Notwithstanding all this, whether in poikilotherms, thyroid hormones have positive metabolic effects, whether they have only non-metabolic effects (e.g. growth and development) or whether other hormones can substitute for them is not clearly investigated and understood. Couple of years back Samir Bhattacharya and his group had elegantly demonstrated the unambiguous role of thyroid hormones in fish reproduction. Now Gupta and Mahanta (**page 326**) have shown that testosterone can function like the thyroid hormone T_4. They are demonstrating positive *in vitro* and *in vivo* effects of the androgen on peripheral tissue respiration.

The judicious use of antihormones (goitrogens and cyproterone acetate) in establishing the role of thyroid and gonadal hormones in calorigenic action *per se* in poikilotherms as well as in demonstrating the ability of thyroid hormone to potentiate the non-shivering calorigenic effect of catecholamines is noteworthy. In these animals, exogenously administered T_4 and T_4 have produced equivocal results in other workers' laboratories.

Hibernation among all phylogenic groups is associated with low metabolic rate. In hibernating mammals, thyroid tends to be inactive during winter months. On the other hand, thyroid exhibits moderate activity in winter months in poikilotherms. Gupta and Mahanta also demonstrate the differential sensitivity of hibernating and non-hibernating frogs to thyroid hormones and the ability of gonadal androgen to substitute for thyroid hormone in both types of poikilotherms.

K. Muralidhar

We'll help you get there

If you're selling science books/journals or laboratory products, or wish to recruit scientists in your establishment, then

you're sure to benefit by advertising here.

Because *Current Science* reaches nearly every university, scientific institution and industrial R&D unit in India. What's more, it's read by hundreds of individual subscribers—students, doctoral scientists and professionals in virtually every field of scientific activity in India,

Current Science has the largest circulation among scientific journals in India.

And to give you more impact, we're now bigger, and better.

CURRENT SCIENCE

Volume 72 Number 5 10 March 1997

CORRESPONDENCE

Science and industry

I found the editorial of the 25 January 1996 issue particularly intriguing and significant. The editors are clearly pointing the journal in the right direction – toward greater contact with industry. In the present world climate for science, it would be suicidal to do anything else. I do not believe that the readers of *Current Science* have been sufficiently exposed to the science – the evolution – of current thought on the value of science not connected to industry and applications. Unknown to most, the model of post World War II American 'pure' or 'basic' science – colonized by the lure of money from the public purse, and mesmerized by the big gadgets of big science – had wreaked havoc on the real purity of 'pure' science. Very few scientists like Tennyson's Ulysses chase 'knowledge like a sinking star'. They are almost totally constrained by money, by fads, by peers, by bureaucracy with necessarily 'political' agendas. As money becomes scarce, US academics, for the wrong reason, look to industry. The major correct reason for linking to industry is that is where interesting, exciting problems – the interface with unexplained manifestations of nature appear. The other reason, of course, is that it is a way to serve the public good, since it is public money we use.

However, paragraph 2 of the editorial is simply wrong. It is the misperception foisted on to the public by the American academics. University–industry interactions are *very weak* compared to the total effort, and they contributed at best in a minuscule way to making these 'great economic powers'. I showed at great length in my book, *Lost at the Frontier* (ISI Press, 1985) and in subsequent papers how the government support of science 'ruined' the pre-war American *real* science where independent universities with modest help from the private sector really linked these two worlds. In chemistry, Speed Marvel and Roger Adams were great examples. In physics, contrary to the general view, Bell Labs was the mecca where *applications-driven* basic science was taken to Nobel heights. The transistor was driven by the most elementary and obvious need to eliminate the filament current drain. It did not originate in quantum mechanical calculations of energy levels. The post World War II government entitlement programmes for academic research while winning lots of Nobel Prizes in abstract science (at some billions of dollars of public money for each) *severed* the university–industry ties.

What Indian scientists should learn is that US (and worldwide) major industries between 1991 and 1993 made the discovery that there is no R.O.I. on basic research. The bogus self-serving economic analyses by academics to the contrary, *basic (undirected) research not connected to a product can never pay to the funder*. (This is a precise integrated statement which should not be truncated at any point, if attributed to me.) The proof is absolute and simple. If 100% of all major corporations that practised the opposite for 40 years (lavishly funding such) have realized their mistake, how can an academic analyst prove that they are wrong. If a company cannot make basic research lab–development lab interaction pay, how can any reasonable scientist claim that the threadbare connection between the results of a lone university researcher be effectively coupled to any one of a thousand companies anywhere in the world.

Indeed the logic of this argument can take us much further – toward 'privatization' (with all sorts of incentives) of *all* undirected truly basic research. Lacking space I can only refer the reader to Cambridge biochemist Terence Kealey's just published book *The Economics of Scientific Research* (St. Martin Press, 1997). It is an absolutely essential resource for anyone thinking about government and industry support of university research. Kealey has marshalled facts and arguments which will dominate the discussion for many years. The core of Britain (and Germany's) basic science was funded in its greatest years by private philanthropy.

I write not as an opponent but as a strong, but highly disciplined advocate of such university–industry (U–I) coupling. MIT and Penn state are and have been neck and neck in the competition for the leading university position in U–I coupling, with nearly $50 million/yr involved. And in that, the Materials Research Lab I started and directed for a quarter of a century remains the outstanding player.

The salient new points for Indian thinking about U–I coupling in today's climate are:

1. The dollar amounts are much smaller than in government grants (factor of 5 to 10).
2. The necessary response times are much shorter (factor of 5).
3. The coupling partners are in globalized setting so that US companies can couple to Indian universities and Indian or Japanese companies can couple with US or European universities. (Our lab does this very effectively today.)
4. Doing this kind of quick response research aimed typically at maximizing the functions of 'cheaper, faster, or greener,' not necessarily performance only, requires a certain mindset not very common among (American) academics.

Hence I subscribe enthusiastically to your editorial's last paragraph: 'it *will* enrich the Indian scientific scene'. But I add to your need for 'imagination and drive' the willingness to change. Perhaps Indian science could learn the lesson (totally ignored by post World War II American science), which Albert Einstein put to a Caltech adulatory crowd in 1931: 'It is not enough that you should understand about applied science in order that your work may increase man's blessings. Concern for man himself and his fate must always form the chief interest of all technical endeavors, concern for the great unsolved problems of the organization of labor and the distribution of goods – in order that the creations of our minds shall be a blessing and not a curse to mankind. Never forget this in the midst of your diagrams and equations.'

Flawed policy of DST and DoE

I wish to state that the statement about DST imposing two draconian conditions on S&T projects submitted to them is not true (P. N. Andhare, *Curr. Sci.*, 1997, **72**, 158–159). As far as support for basic Science and Engineering Research is concerned, the scientific merit is the only ground on which funds are provided. Only on projects of applied nature, it is the policy to nurture linkages between research community and industry, and preference is given to projects involving industrial participation. During the year 1995–96, Science and Engineering Research Council has supported over 300 projects and spent Rs 37 crores approximately and scientific merit has been the only criterion in supporting these projects.

V. RAO AIYAGARI

Department of Science & Technology,
Technology Bhavan, New Mehrauli Road,
New Delhi 110016, India

P. N. Andhare accuses the DST and DoE of imposing 'draconian conditions that they nip in the bud *any* S&T proposal even before its evaluation on scientific merit' (emphasis added). The two conditions are (paraphrasing) (i) every proposal must have financial support from industry, and (ii) industry must give an undertaking in advance to productionize the R&D resulting from the proposal. In my capacity as the Chairman of the Programme Advisory Committee on Robotics and Manufacturing of the Department of Science and Technology, I would like to make it clear that the above-stated requirements are *not* preconditions for a proposal to be funded by DST.

Let me begin by giving a few statistics: The PAC-RM (and its predecessor, the PAC on Manufacturing Technology) have over the years made it a policy to nurture interaction between the research community and industry. Since 1991, the PAC has funded (after approval by SERC) a total of 39 projects at an outlay of Rs 512 lakhs. Of these, 18 projects have received partial funding from industry and other agencies to the tune of Rs 178 lakhs. Thus, the industrial support has been approximately one-third of the total funding. On the other hand, it can be seen that the majority of projects funded by PAC-RM have *not* received any industrial funding. Thus, Andhare is not correct in stating that 'any' project must have industrial funding in order to be considered. The statistics above (from a PAC that is among the most 'practical' in DST) bear this out.

Speaking as an individual, I would say that in order to qualify for funding, a research project must *either* consist of top-quality basic research, *or* address a problem of relevance to industry. In the former case, the criteria for assessing a project are the familiar ones, namely the past record of the researchers, the likelihood of the outcome of the research being published in top-quality journals, and so on. In the latter case, a major criterion for judging the relevance of a project to Indian industry must surely be the willingness of the industry to underwrite the cost of the project. There is nothing unreasonable about this criterion.

Unfortunately what happens far too often in our country is that people try to pass off as 'practical' projects whose only notable feature is a total absence of any novel theoretical ideas. Thus the operative presumptions seems to be that if a project will not contribute to basic research, it must therefore be deemed to be 'practical'. In such situations, I see nothing wrong in calling the bluff of such proposers by asking them which industry is interested in their work, and why such industries are not paying at least a part of the cost of the project.

Let me repeat that if a person is doing basic research work at an internationally competitive level, then industrial participation is not called for at all. On the other hand, stringent steps must be taken to guard against persons trying to pass off third-rate theoretical or 'applied' work as 'practical' R&D.

Finally, I cannot agree with Andhare's railing against 'market' forces in S&T. Whether he acknowledges it or not, there are *always* 'market' forces at work in every arena, not excepting S&T. Even carrying out 'basic' research is subject to 'market' forces. Why else do new ideas suddenly become 'hot' while others becomes 'cold', even in purely theoretical subjects such as mathematics? In order to publish a paper, even in purely theoretical subjects, it is necessary to make a substantial contribution *on a topic in which the research community is interested.* No journal will publish a paper on a topic that is deemed by the community to be outdated or not of interest to anyone. Unfortunately what some persons want in our country is not academic freedom, but rather freedom from accountability. But that would be licence and not freedom.

Essentials of Nuclear Chemistry: Critique of a review

P. S. Goel's comments on my book (*Curr. Sci.*, 1996, **71**, 155–156) can be grouped under six heads: (1) Quoting unupdated values of some constants, (2) Conceptual errors, (3) Irrelevant references, (4) Mathematical errors (only two), (5) Use of outdated cosmological models, and (6) Language problems.

While the values of fundamental constants have been determined with high precision and are universally accepted, there are some of limited applicability whose values are known with less accuracy. Under this category come the proton decay constant, the ^{14}C content of living matter, the ages of the oldest rocks and of the earth. In fact, proton decay as a distinct form of radioactivity is yet to be accorded international recognition. This value, quoted in a footnote in my book, was taken from a popular lecture by an eminent scientist in the Indian Science Congress session of 1982. Since then there has been no new information on the subject. The approximate value quoted by me, viz. one proton out of 10^{30} per month was only to indicate the great rarity of proton decay. Similarly, all the workers on dating by ^{14}C are not agreed on the exact content of this isotope in living organic matter. Values cited vary from 13.6 to 16 c min^{-1} g^{-1}. I have only stated this fact in my book. Similar remarks apply to the assessment by different workers of the age of the oldest rocks of the world and of the age of the earth based on $^{40}Ar/^{40}K$ ratio. Stating these facts cannot imply lack of updating.

If I have referred to Urey's work in this context, it is because the famous geologist K. Rankama too had referred to Urey, not once, but some 30 times, in his classic work, *Isotope Geology* (McGraw-Hill, 1954). It is not clear how my referring to the Nobel laureate's work can be considered 'blatant misinformation'. My description of the term 'nuclide' as a given combination of *Z* protons and *N* neutrons in the nucleus, without referring to *Z* electrons in the outer sphere, and of 'isobars' as nuclides with a constant nucleon number A ($\equiv Z+N$), are succinct and error-free. Yet these are cited as examples of conceptional errors without pointing the error. Similarly, the numbers of stable odd *A* nuclides, 50 with Z-odd and 55 with *N*-odd being nearly the same, show *the charge-independent nature of the stability of odd-A nuclides.* This statement is also considered as a conceptual error. Similarly, the review includes other statements of mine as involving conceptual errors, without the errors being pointed out.

Goel has rightly pointed out two grave mathematical errors, (i) p. 134, last line, the expression $e^{(\lambda_1-\lambda_2)}$ should read $e^{(\lambda_1-\lambda_2)t}$. The correct expression is used in the table on p. 135 and elsewhere. (ii) The second error refers to the calculation of the surface area of 1 g of barium sulphate precipitate (p. 383, line 13), the formula weight of $BaSO_4$ is 233.4 and not 223 as given. This leads to a value of 19.51×10^{-16} cm^2 g^{-1} instead of 4.11 cm^2 g^{-1} as pointed. I am grateful to Goel for pointing out these two errors. These will be rectified at the time of the next reprint.

It is unfortunate that Goel did not see a single positive point in the 500-page fourth edition. The book has been reviewed by some others as well and it is widely used in the country and outside and has been translated into the Serbo-Croatian by the Faculty of the University of Belgrade and into Iranian by the Iranian Atomic Energy Organization.

Science policy in neo-liberal India: Corporate culture, basic science and scientific credibility*

Suresh K. Mahajan

In the present neo-liberal era, there is great pressure to introduce corporate culture in managing Indian science and scientists and to de-emphasize basic science in favour of developing immediately useful technologies. This is ironic because the performance of our better universities and R&D institutions has been much closer to international standards than that of our corporate sector. With very few exceptions, the latter has been almost inimical to indigenous R&D. Nearly all serious scientists have worked in public-funded institutions. The demands of corporate culture are likely to accelerate the flight of bright youngsters from scientific careers and even reduce the credibility of science.

Introduction

The Science Policy Resolution adopted by the Parliament on 4 March 1958 stated that the aims of the scientific policy of the Government of India would be:

(i) to foster, promote and sustain, by all appropriate means, the cultivation of science and scientific research in all its aspects – pure, applied and educational;

(ii) to ensure an adequate supply, within the country, of research scientists of the highest quality, and to recognize their work as an important component of the strength of the nation;

(iii) to encourage and initiate, with all possible speed, programmes for the training of scientific and technical personnel

---

*Based on a lecture delivered by the author on 24 January 1997 at a seminar on 'Science policy and scientific temper', organized by the Dept of Civics and History, University of Bombay.

on a scale adequate to fulfil the country's needs in science and education, in agriculture and industry, and defence;
(iv) to ensure that the creative talent of men and women is encouraged and finds full scope in scientific activity;
(v) to encourage individual initiative for the acquisition and dissemination of knowledge and for the discovery of new knowledge, in an atmosphere of academic freedom;
(vi) and, in general, to secure for the people of the country all the benefits that can accrue from the acquisition and application of scientific knowledge.

The SPR further stated that: 'the Government of India has decided to pursue and accomplish these aims by offering them an *honoured position*, by associating scientists with the formulation of policies and by taking such other measures as may be deemed necessary from time to time'.

The preamble to the resolution recognized that 'it (science) has not only altered man's material environment, but, what is of still deeper significance, it has provided a new tool to thoughts and has expanded man's mental horizon'.

The major moving thought behind this resolution was the realization that of the three main factors, namely technology, raw materials and capital that hold the key to national prosperity, technology was the most important. However, it also asserted that 'it is an inherent obligation of a great country like India, with its tradition of scholarship and original thinking and its great cultural heritage, to participate fully in the march of science, which is probably *mankind's greatest enterprise today*'.

It is now nearly four decades since the adoption of the above resolution. India is in the 50th year of its independence and the world is on the threshold of the 21st century. Indian science is in turmoil, and its public image is not very bright. Serious scientists are under great pressure to accept the culture of the corporate sector which in the Indian context has contributed little to R&D and produced hardly any goods or services of international standard. And most, including those who ought to know better, are succumbing to these pressures. Even the best scientific institutions are increasingly becoming unpleasant places to work, with a crude authoritarianism creeping in and academic freedom and scientific values not receiving the importance they deserve. Scientifically tainted individuals can today receive both protection and power merely by promising relevance (often the last resort of the mediocre) or ECF (external cash flow). Managers of science enjoy great power within their institutions but little credibility outside. Bright youngsters increasingly consider a career in basic science an unattractive proposition. Though many still flock to engineering, their final destination is mostly marketing and management and rarely ever development of advanced technology.

It is certainly an apt time for stocktaking. What has gone wrong? Has the performance of Indian science been really as bad as its reputation in certain quarters in this country would indicate? Were the dreams of the Indian architects of the SPR (Nehru and Homi Bhabha) unrealistic or unjustified? Have the policies enunciated in SPR become irrelevant now? If not, then why are scientists being forced to act against these policy directives? Has Indian science been wrongly maligned by the sustained campaign of anti-science ideologues and vested interests? Is it suffering because of the sins of its own managers and/or due to intellectual laziness and timidity of its foot soldiers? Or is the corporate sector, which has shown little inclination to invest in R&D, trying to hijack the S&T infrastructure and competence diligently created in the public sector by an enlightened government? How do the public investments in science compare with material returns that society has received from this investment? What is the nexus between developing S&T infrastructure and scientific temper? How much of the current pressures on Indian science are due to Indian people's disenchantment with science and how much of these are merely due to internal contradictions between basic scientists and technologists, and between power hungry careerists and serious scientists? How much of these are due to international trends and fashions? How much has our official scientific enterprise contributed to the development of scientific temper among our people? What role have the NGOs played in this regard? What more can the latter do? Is it desirable, or even safe, to leave the making and implementation of science policy totally in the hands of scientists and technologists who may not have had the time or inclination to educate themselves in the related sociological, philosophical, historical and intellectual issues? Is there a need for writing a critical history of the development of Indian science in recent decades? If yes, who should write it? Should it be scientists who have watched the working of our R&D institutions and science departments as insiders? Or should it be professionally trained historians with science education? Those who have enjoyed enormous power in Indian science must be subjected to historical accountability. But how are we going to do that?

These and many more questions need to be asked by our science policy makers, those charged with implementation of these policies, the working scientists and concerned individuals in other fields of intellectual activity. Here I shall try to give my views on some of these questions. These are entirely personal views of someone who entered a scientific career just a few years after the SPR was adopted and who has been dismayed in recent years by steady attacks on the achievements of Indian science both from within and outside and the resultant decline in the attractiveness of science as a career. These are also the views of someone who is concerned that the recent emphasis on introducing corporate culture into Indian science is likely to further drive away bright youngsters from science leading to decline in its performance which is unlikely to help the country in the long run. Perhaps even more importantly, the introduction of corporate culture may reduce the credibility of scientists and science, built by a scientific culture which demands much higher levels of objectivity and integrity than found in any profit-oriented, pragmatic culture.

Performance of Indian science

There is a general belief in this country that Indian science has not done well in the post-Independence era. Usually, three facts are cited to support this view. First, in recent years we have not produced outstanding scientists of the eminence of Raman, Bose and Saha, as highlighted in a recent *Times of India* article by J. Narlikar. Second, Indian S&T has not made significant contributions towards developing technologies for our industry. And, third, in spite of investments in S&T, we have not been able to solve our problems of poverty and underdevelopment. On all the three counts the criticism is less justified than it appears at the first sight. This point needs to be explained and emphasized as the constant criticism, especially when it comes from quarters which have no anti-science bias, can reduce public support for S&T and make science less attractive as a career option for brighter students. The consequences of this can be serious for our national image and development in the long run.

Narlikar considers the neglect of our university system, the parochial political considerations in the running of our universities, and the failure of the research institutes to have teaching programmes and attract young students as some of the main causes of our failure to produce scientific stars. All these are valid criticisms and corrective action should help. However, there is another side to the story. The performance of our universities and national research institutes has not been really as poor as most of us seem to believe. It is true that both in terms of production of scientific stars and developing novel technologies, our record compares unfavourably with that of the more advanced countries, especially the USA, with which we seem all the time to compare ourselves. But this is not a fair comparison, given the relative levels of our investments in science and the general level of our economic, industrial and socio-political development. It is more realistic and revealing to compare the records of our science education and R&D sectors with those of other sectors of our national life. While almost nothing produced by our private sector (be it a cake of soap, a pair of shoes or trousers, a news magazine, or a radio set) could be sold in the supermarkets of advanced nations until recently, the best products of our universities and research institutes, (viz. the students, scientists and research papers) have been of international standards and have sold in the most competitive global markets. Is there any other field outside our higher education and R&D system (with probable exceptions in the areas of purely Indian culture, such as classical music) which can make such a claim?

It is not insignificant that in the present liberalization the one factor which most international investors find attractive about this country is the abundance of highly skilled technical manpower. If today many advanced countries are trying to stop the entry of Indian scientists and technologists into their countries because they successfully compete with their own citizens for the best paid jobs, surely for this state of affairs some credit has to be given to what Indian universities and scientific institutes have been doing. This is perhaps a better index of good performance of post-independence Indian science than even the few memberships of the International Academies and invitations to Plenary Lectures (as pointed out by Narlikar), though I have absolutely no intention of belittling the latter honours earned against heavy odds. Certainly, the achievements of India-trained scientists and technologists in the post-independent era have done more than did Ramans, Sahas and Boses in changing the image of the country from an abode of *sadhus* and snake charmers to that of a major reservoir of scientific and technological personnel. Today, one hardly hears of the Hindu (read irrational) mind, which was a common phrase in western discussion of India up to the fifties and sixties.

Ramans, Sahas and Boses remain important role models and sources of national pride to India. But it should be recognized that the world in which they operated was very different from the post war world available to the later Indian scientists. It should be remembered that during the last few decades even the more advanced nations of western Europe have lost large number of elite scientists and brightest students to the US which has provided a working environment and facilities not available elsewhere.

Impressed by its experience during the second World War when numerous expatriate scientists from Europe played key roles in the Manhattan project and elsewhere, the US, as a matter of policy, provided a hospitable and attractive environment to scientists, technologists and bright students from all parts of the globe. Government support for research expanded rapidly. Professors received funds to hire large teams of best available graduate students and post-doctoral fellows from anywhere in the world. In this they succeeded admirably because the research facilities, the liberal intellectual environment, and the salaries available in the US were too irresistible for most students and scientists elsewhere in the world. Many pieces of equipment, chemicals, etc., which were earlier made by scientists themselves, became available commercially which gave a big advantage to those with more money and proximity to the centres of production. Little wonder that suddenly most of the star scientists were to be found in the US. Not only did India's Chandrasekhar, Khorana, Inder Verma, and Ananda Chakravarty choose to emigrate to the US, so did some of the best scientists from most other major nations. If a young Raman or Saha in post-independence India had resisted the temptation to emigrate to the US and doggedly stayed on in India, he would be functioning under considerably greater relative handicaps than he faced in the earlier era. If he had continued to work on exciting contemporary problems, he would have had many more competitors working on the same problems and supported by better facilities, brighter students and better trained post-doctoral fellows. The chances of his being scooped would be quite high. In the first past-the-post system of scientific credit, Raman and Saha might have received no credit for the work done by them.

Under such circumstances, it is indeed remarkable that India has retained sufficiently large number of good scientists to keep the standards reasonably high. The important point here is that our failure to retain some of our best students and scientists is less due to the manner in which our universities and research institutes have functioned and more due to our socio-economic conditions and policies originating elsewhere, about which we could have done nothing.

As to the question of our record in developing technologies for our industry, I think the reason lies again in the state of our economic development. Our industrialists, with limited capital from international standards and a vast captive market, have behaved quite rationally in acquiring proven, even if dated, technologies from elsewhere and using them to manufacture goods for our needs which Indian consumers accepted readily. To expect our industrialists to compete with the multinationals in R&D, or to use only the (unproven) technologies developed in Indian research laboratories, would require them to be financially imprudent. It is, therefore, not surprising that even though during the last 50 years most of the CSIR laboratories have concentrated on applied research (it is a mistake to think, as some seem to do, that the stress on industrial research in CSIR laboratories is a new phenomenon), few of its technologies have been used by Indian industry. Even in the future only such technologies developed by the CSIR are likely to see the light of the day as are sold to the major (mostly multinational) companies with in-house R&D capabilities to develop them into marketable products. It is unrealistic to expect Indian scientists and technologists to compete with international industrial houses in generating marketable technologies of comparable standards, without even the benefit of interacting with the user industries.

In advanced countries, scientists and technologists in publicly funded R&D institutes only generate technology ideas which are then developed into technologies and products by industrial scientists. Under the best of circumstances, scientists in Indian government institutions could be expected to compete with their counterparts elsewhere, not with the researchers working in industry. The main point is that though Indian industry has its own reasons for not using the technologies developed in public funded Indian research laboratories, as well as for not investing in in-house R&D of its own when it could easily buy ready-made technologies of standards acceptable to the Indian consumers, these reasons were not good enough to hold Indian scientists exclusively responsible for not developing and transferring technologies to the Indian industry. Indian research laboratories could have succeeded in transferring technologies to Indian industry only if the latter had no access to the proven technologies in the international market. This, of course, would not happen in non-strategic areas. International industry would not like its potential competitors to grow, if all that was required to stop it was to offer its obsolete technologies, and may be a few foreign trips, to the Indian industrial managers.

It is noteworthy here that in strategic areas such as atomic energy, defense and space, where the advanced nations were not willing to part with their technologies, Indian scientists and engineers have a much better record of the utilization of their efforts, even though the unavoidable teething troubles may have made these developments relatively slow.

Coming to the question of the contributions of Indian R&D to poverty removal and development, firstly it must be recognized that these contributions have not been insignificant. If we have not had a famine for the last 30 years and a war for the last 25 years and if our life expectancy has improved substantially, some credit for it does go to our S&T sector. Even if the contribution of agricultural scientists to the increased food grain production (approximately 140 million tonnes per year in the post-independent era) is calculated at Rs 1/kg (i.e. about 20% of the actual cost), this works out to a staggering Rs 1,400 crores per year, certainly much more than our total annual expenditure on R&D. Taken as a whole, Indian R&D is clearly more than paying its way. Our poverty and underdevelopment certainly remain. But to think that these problems will be solved faster by further reducing our already meagre investments in R&D, or by introducing corporate culture into our publicly funded R&D institutions is unrealistic. Such steps can only destroy what has been achieved, make scientific careers still more unattractive, and further aggravate our problems in the future. Our real problems lie in lack of capital and an ineffective population policy, especially the latter, on which we are silent these days.

Useful technologies vs basic research

Our tendency to be over-critical of ourselves and failure to appreciate that we have been doing something right about our higher education and S&T, has created an environment in which there is a real danger that much of the past good work may be undone. I refer here to the excessive emphasis in the last few years on support of only immediately useful S&T. Not only are the national laboratories being pressurized to de-emphasize basic science, which is absolutely essential to maintain high standards, but even the universities are being exhorted to become handmaidens of industry which, understandably, would support only short-term projects with prospects of immediate profits.

It is pertinent to note that the emphasis on immediately useful science and reduced support for basic science is not an original Indian idea. This is an imitation of what has become a fashion in several advanced countries since the era of Reagan and Thatcher. This is also true of the exhortations to the scientists to establish linkages with industry. This development has disturbed several of the more thinking scientists and intellectuals in the West who have articulated the risks involved in this approach. For instance, in a recent letter to the *Science* (16 August 1996), Nobel Laureate Arthur Kornberg pointed out that the antibiotic penicillin, as well as the entire molecular biology leading to the Human Genome Project (HGP) and bio-technology, would not have been possible, but for the support to the relatively unplanned, curiosity-driven research. At the same time, according to him, the high level of planned support to anti-cancer research has yielded much poorer dividends, because the knowledge generated to solve the problem simply did not exist.

Several other points which have recently appeared in international literature are of relevance in the context. A study conducted by the Science Policy Research Unit at the University of Sussex in the UK, has concluded that the economic impact of basic research has to be measured not only in terms of the value of the knowledge that it generates, but also in terms of producing the trained manpower which can make use of such knowledge, even if it is generated elsewhere. This is extremely important in our case. To cite an example, benefits emanating from the HGP are not going to be finally utilized by the needy countries if there is no trained manpower contributing to the generation of this knowledge. Hence, India would be making full use of knowledge generated by the HGP only if it invests money in projects aimed at generating knowledge in this area, even if this knowledge may not bring us glory that the advanced nations with their much bigger investments will corner. India will at least generate manpower needed for using the internationally available knowledge in patient care, in reducing the genetic load in our population, and in utilizing the technologies spun off by this project in agriculture, animal husbandry and molecular anthropology. The architects of our SPR, much more realistic as they were than some of our present-day critics and managers, would have been satisfied with the above as our initial goal.

In a beautifully argued article (*Interdiscip. Sci. Rev.*, 1995, **20**, 281–288), reproduced in *Current Science* (1996, **71**, 148), Martin Rees points out that a panel set up by the National Academy of Sciences, USA, in 1937 to predict the technologies of the following few decades, did *not* include among its predictions the nuclear power, transistors, antibiotics, jet aircraft, rocketry, or computers. All these developments were possible because in the post-war era the US government invested heavily in supporting curiosity-driven, investigator-initiated research projects in areas of *no obvious* immediate benefits. In contrast, the USSR which greatly emphasized the utilitarian science over basic science, contributed relatively much less to the development of novel technologies which have changed the world today. (It is, perhaps, not irrelevant to refer here to T. D. Lysenko who emphasized the empirical agricultural technology like vernalization and used his friendship with Stalin to decimate the growth of genetics in the USSR; the consequent failure of the USSR agriculture to grow food crops at the required levels in the long run played a key role in the failure of the entire Soviet experiment.)

Black holes and dinosaurs

Another interesting point made by Rees in his essay is that the common people have maximum interest in some of the areas of science with hardly any conceivable use. Cosmology and dinosaurs are much more likely to make front-page news than any of the more useful technological breakthroughs. This supports a feeling I have always had that most of the attacks on basic science really do not come from general public but are generated by the internal politics within the scientific community. Rees also points out that a football team in which each player has to score goals in order to retain his place is unlikely to be a functional outfit. This should be a sobering thought for those, including some very influential policy makers, who would like to support only such basic researchers the impact of whose research is visible to all. It is essential to maintain a broad science base and a web of connections between different disciplines.

Threat to credibility of science

John Ziman, Emeritus Professor of Physics at the University of Bristol, pointed out in his 1995 Medawar lecture that in the current emphasis everywhere on useful research what is at stake is the very 'objectivity' of science. Scientists who are employed to do useful science will clearly not be in a position to publish their findings if they go against the interests of their employers. The implication of this is that the credibility of science and scientists will take a serious beating. It was the objectivity of science and the relative, even though not absolute, disinterest of the scientists in the benefits of their work that gave science a unique prestige as a methodology of generating knowledge. Science as a cultural and intellectual activity will lose its credibility, and in the long run will also lose its ability to benefit society and generate knowledge and technology, if public funding and prestige is denied to those who are willing to work in intellectually challenging areas even if the potential applications of their work are not apparent in the beginning.

Lastly, it is important not to ignore the lessons of history. Two examples, one of a long-term and the other of short-term historical context should suffice to make my point. (i) During the centuries immediately preceding the British colonization, India was ruled by one of the most powerful empires – the Mogul empire – in history. During this period, India had acquired, developed and used a large number of useful technologies in diverse areas such as production of textiles, fancy gold and silver embroidery, metal work, architecture, traditional medicine, perfumes, sophisticated musical instruments, etc. The country was sufficiently wealthy to attract traders from far away lands. However, little attention was paid to keeping track of the advances in S&T taking place elsewhere and to making original contributions to the advancement of knowledge in these areas. The result was that European traders could extract large concessions from Indian emperors simply by holding out the threat of attacking the Haj ships on the high seas to which Indians had no answer. Perhaps, even more importantly, the achievements of the Europeans in S&T so dazzled the Indian intelligentsia that many readily supported their rule, which was certainly an important factor in the easy colonization of India by Britain. (ii) The Government of India had created two Research Councils (viz. ICAR and ICMR) in the area of applied biology. The two have made major contributions toward improving our food production and health standards respectively. However, they made the mistake of concentrating almost exclusively on immediately useful projects and paid little attention to developing expertise in basic biology on which their future performance would depend. The result was that when in the 1980s the conceptual framework earlier developed by molecular biology altered the technological basis of modern agriculture and medicine, the ICAR and the ICMR had insufficient competence to exploit the new technologies. Nearly all the funding for molecular agriculture and molecular medicine had to come from the newly created Department of Biotechnology, and most work in these areas had to be done in the Institutions outside the purview of ICAR and ICMR. One shudders to think as to what would have happened to basic as well as applied biology in this country if the Government of India had not either created the DBT or if this Department had not been lucky to have an enlightened leadership which recognized the importance of basic science in developing technology. One hopes that other agencies which are keen to deemphasize basic research would learn the lessons from our earlier experiences.

To summarize, a realistic assessment in the light of the SPR shows that the performance of the Indian S&T sector, especially the R&D institutions and universities, which cultivated all aspects of science (pure, applied and educational), and gave reasonable encouragement to creative talent and individual initiative in generation of new knowledge in an atmosphere of academic freedom, has not been as bad as is generally believed in this country. They have succeeded in producing research scientists of international standard and in training large numbers of scientific and technical personnel who are a major source of our strength as a nation today and who can help in rapid industrialization of the nation, given adequate capital and proper economic and industrial policies. These institutions and basic research need continuous support. Our emphasis on immediately useful research at the expense of basic science can kill the goose that lays the golden eggs.

Fertilization in flowering plants – What is new?

K. R. Shivanna and N. S. Rangaswamy

The process of fertilization is more complex in flowering plants than in other groups of plants. Following successful pollination, a pollen grain germinates on the stigma and the resulting pollen tube grows through the stigma and style and carries the two male gametes into the ovule. Eventually the pollen tube enters the embryo sac and releases the male gametes. One of the male gametes fuses with the egg to form the zygote and the other with the central cell to produce the endosperm, thus completing the process of double fertilization, a unique feature of flowering plants. The zygote gives rise to the embryo; the central cell-derived endosperm nourishes the embryo. Thus, fertilization in flowering plants takes place deep inside the ovule and imposes technical problems for basic studies as well as for effective experimentation. Because of this constraint, our knowledge of fertilization in flowering plants has been rather meagre and lags far behind that in animals and some lower plants in which fertilization is external and can be observed under the microscope. One of the main objectives of the experimental embryologist has been to achieve fertilization *in vitro* by using isolated egg and sperm cells, and development of the *in vitro* formed zygote into embryo. This would enable effective experimentation on fertilization in flowering plants comparable to that in animals and lower plants.

A beginning on these lines was made over 30 years ago in the laboratory of the late Panchanan Maheshwari at the University of Delhi. Maheshwari and his associates[1] cultured isolated groups of ovules and pollen grains of opium poppy (*Papaver somniferum*) together on a nutrient medium. Pollen germination, pollen tube entry into ovules and double fertilization proceeded normally; the fertilized ovules developed into viable seeds; this research report in *Nature* was covered in leading newspapers in India and abroad. Subsequently the technique was refined to minimize injury to the ovules and to overcome self-incompatibility[2]. Although the technique has been successfully used over the years to overcome crossability barriers in several species[3,4], progress in advancing the technique to achieve *in vitro* fertilization with isolated egg and sperm cells was hampered for want of techniques to isolate viable male gametes (sperms) and eggs and fuse them *in vitro* to achieve fertilization.

Rapid advances in protoplast technology and somatic hybridization during the 1970s and the 1980s gave new impetus to studies on *in vitro* fertilization. Recent progress in recombinant DNA technology, which made the egg, sperm and zygote very attractive systems for genetic transformation, compounded the interest in research on *in vitro* fertilization. Studies were initiated the world over on isolation of sperms and embryo sacs in the early 1980s and the progress was overwhelming[5]. Basically two procedures were employed to isolate sperms from pollen grains: mechanical method and osmotic shock method. In the first, the pollen grains are ruptured mechanically by grinding them in isolation medium, and in the second by incubating the pollen grains in a hypotonic solution. The debris is removed through filtration and the sperms are then separated through density gradient centrifugation. Embryo sacs are generally isolated by combining enzymic maceration of ovules with microdissection. Subsequently the technique was further refined to isolate protoplasts from constituent cells of the embryo sac (egg, synergids and central cell). Thus, by 1990, protocols were available for isolation of viable protoplasts from sperms and eggs of many plant species, and the stage was set to make serious attempts to achieve *in vitro* fertilization.

The pioneering success of fusing isolated egg and sperm cells *in vitro* was accomplished in maize by Kranz and his associates at the University of Hamburg in 1991 (ref. 6). It took another 2 years to standardize the conditions to realize embryogenesis and plantlet formation from *in vitro*-formed zygotes[7]. The fusion of gametes was performed under the microscope in microdroplets (2 μl) of fusion medium covered with mineral oil. Isolated egg and sperm cells held in microcapillaries were transferred to the fusion droplets by using a computer-controlled dispenser. The egg and sperm cells were aligned electrophoretically or mechanically with microneedles and fusion was induced by giving one or a few short pulses of direct current. The fusion was completed in <1 s and karyogamy occurred in <1 h from fusion. As in somatic protoplast fusion, in gametic fusion also the composition and osmolarity of the medium were critical. The *in vitro*-formed zygotes were cultured on a semipermeable membrane placed on fast growing nonmorphogenetic cell suspension cultures derived from maize embryo or microspores. In these nurse cultures the zygotes established polarity, showed as high as 85% division, and gave rise to globular structures, proembryos and transition phase embryos comparable to seed embryos *in vivo*, and eventually to fertile plants.

Next, *in vitro* fusion of isolated gametes in maize was achieved not with electric pulse but in the presence of high calcium[8] and high alkalinity (pH 11) (ref. 9); also, attempts were made to microinject sperm nuclei into isolated embryo sacs[10]. Furthermore, it has been possible to regenerate whole plants of maize by culturing the *in vivo*-formed zygote[11]. Recently sperm cell has been fused with the central cell also; the resultant fusion product was capable of growth comparable to endosperm[12]. A further milestone has been the demonstration that the fusion product of maize egg and sperm of the related genera, wheat and sorghum, underwent divisions, but not that of maize egg and sperm of the unrelated genus *Brassica*. Even more significant has been that the fusion product of two maize eggs failed to undergo divisions[11]. Most of the achievements of the past decade on *in vitro* fertilization have been with maize, and there is no compelling reason to disclaim that the various techniques employed will not work equally well with other higher plant species.

The advances on *in vitro* fertilization and embryogenesis have opened up a vista of experimental studies. Some of the fundamental problems that can be effectively researched on (using the technique of *in vitro* fertilization) are: (a) mechanisms of recognition, adhesion

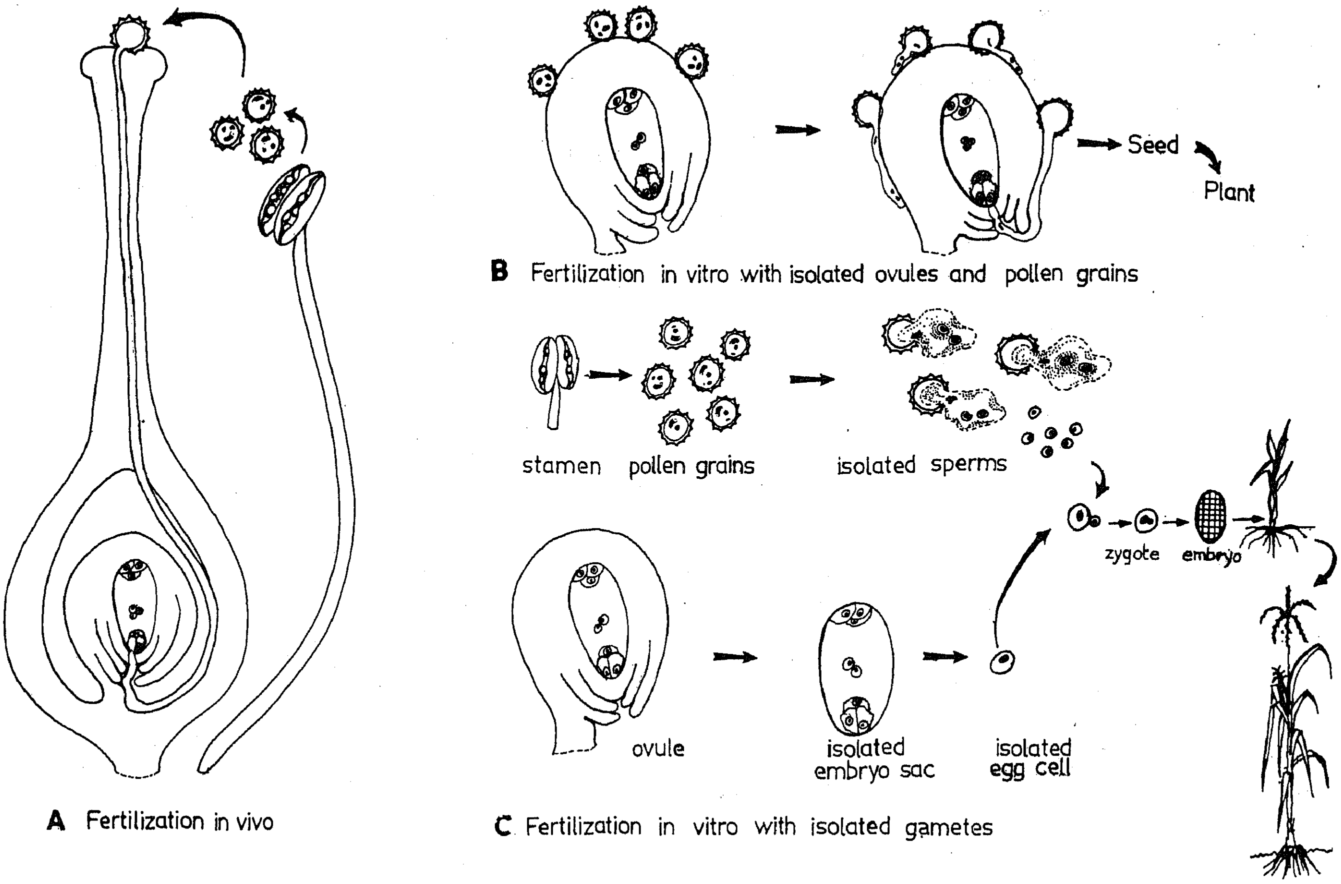

Figure 1. Diagrammatic representation of fertilization *in vivo* and *in vitro*.

and fusion of gametes, (b) parthenogenesis, (c) polyspermy, (d) establishment of polarity in the zygote, and (e) genetic regulation of early embryogenesis.

Indeed, *in vitro* fertilization and embryogenesis provide a very powerful biotechnological tool. Besides its potential application in overcoming incompatibility barriers, its application in genetic transformation studies using the sperm, or the egg, or the zygote is very promising. Studies have already been initiated on these lines; of late a paper from Duma's laboratory (Lyon, France[13]) describes optimal conditions for efficient microinjection of DNA into cultured maize zygotes and transient expression of the microinjected genes in the zygote. It is needless to emphasize that researches on fertilization in flowering plants have entered an exciting phase; in the coming years rapid progress not only in understanding the process but also in exploiting it for crop improvement will accrue, and indeed many a young plant scientist will find the work a much rewarding avocation. And who knows, *in vitro* fertilization may lead to raising a hybrid between the two groups of seed plants in not too distant a future!

New light on the antiquity of Siwalik Great apes

Until now, fossil hominids in the Siwaliks of Indian subcontinent were known from Chinji–Dhokpathan successions ranging between 13.1 and 5.1 m.y. (ref. 1). We document here two isolated hominid teeth (coll. SSG), a sivapithecine molar and a dryopithecine incisor collected from a vertebrate fossil-bearing succession resting conformably over the Upper Murree exposed at Ramchand in Udhampur district, J&K (Figure 1). Ramchand is situated about 10 km southeast of the classic vertebrate fossil locality of Ramnagar from where many vertebrate collections including hominids have been reported earlier[2–4].

Though the newly discovered fossil material is scanty, the specimens hold considerable significance in view of the extreme rarity of hominid fossils in Siwaliks, and more for their provenance from a much older stratigraphic level than previously known from this region. The find has an important bearing on the question of hominid diversification and their global distribution and migration patterns during Early Miocene.

The isolated molar tooth (Figure 2 *a–c*) was extracted *quasi in situ* from a sandstone bed, southeast of Ramchand Ridge, resting 100 m above the Murree/Dodenal (= Kamlial) Member contact[5]. It has suffered damage as a result of which its posterior part is missing. However, on the basis of morphological details of its well-preserved anterior two cusps, viz. protoconid and metaconid, and the enamel folds, the molar is indisputably referable to the genus *Sivapithecus* Pilgrim. The specimen represents the lower left last molar and evidently belongs to a robust form intermediate between *Sivapithecus indicus* Piligrim and *S. giganteus* (Piligrim)[6,7].

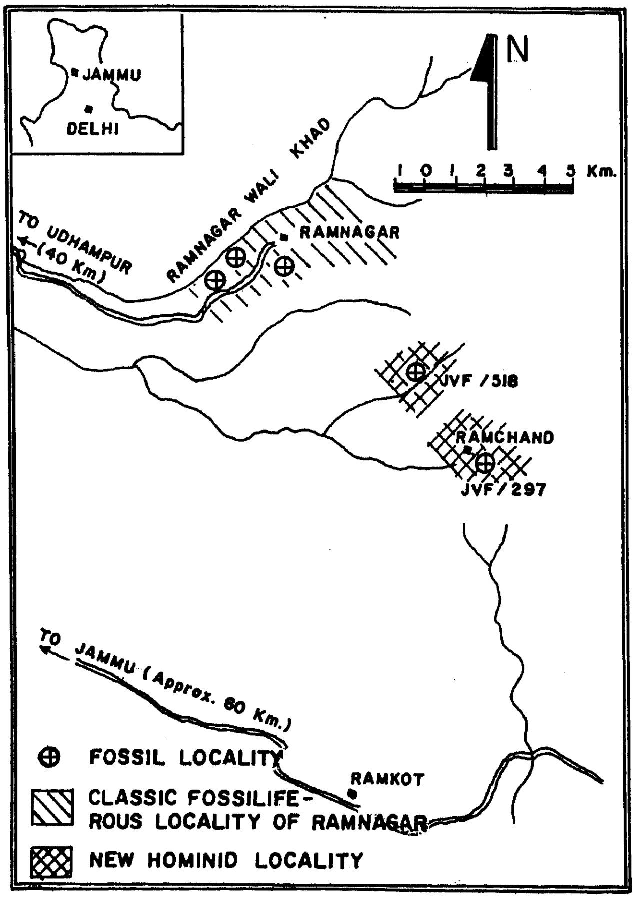

Figure 1. Map showing the classic fossiliferous locality of Ramnagar and the new hominid sites near Ramchand, Udhampur district, J&K.

The other specimen, an isolated upper incisor (Figure 2 *d, e*) was extracted from a sandstone layer resting stratigraphically about 600 m up in the same continuous succession west of Ramchand (Figure 3). The source bed falls in the gradational contact zone of Dodenal/Ramnagar (= Chinji) Member[5]. The enamel folds on the internal side and wear pattern of the crown suggest the tooth to be of a large dryopithecine. We have provisionally assigned it to the genus *Dryopithecus* Lartet.

The Ramchand–Ramnagar section exhibits an uninterrupted sequence of Upper Murree to Middle Siwalik and consists of an enormous pile (4000 m) of sand/siltstone, red clay/shale and mudstone alterations (Figure 3) with gentle dips (8–20°) to the northwest. Ramnagar vertebrate fossiliferous horizon is located near the top of this succession whereas the present *Sivapithecus* yielding horizon stratigraphically lies about 1500 m below the Ramnagar hominid level. The incisor tooth was found near the middle of this succession.

Associated fragmentary vertebrate fossils recovered from vicinity of the *Sivapithecus* site, within 200 m of the stratigraphic column above the Murree Lower Siwalik contact include forms such as: Siluridae indet., *Trionyx* sp., *Gavialis* sp., *Deinotherium* sp., *Gomphotherium* sp. cf. *G. angustidens*, *Aceratherium* sp., Suidae indet., Tragulidae indet., *Dorcabune* sp., *Dorcatherium* sp., Anthracotheriidae indet.

Numerous other fragmentary limb bones, isolated vertebrae, coprolite and scutes belonging to fishes, chelonia snakes, etc. also form part of the faunal assemblage recovered from the Ramchand hominid locality.

The Murree/Lower Siwalik contact, particularly the base of Kamlial has been found to occur near the top of Chron 17 (18.3 m.y.) in Kamlial/Chinji stratotype in Pakistan[8], which is about 200 km from Ramchand as the crow flies. Since the Murree/Lower Siwalik lithologies show lateral continuity over large distances, we presume approximately the same age for our *Sivapithecus* molar specimen and aforelisted fauna. The assemblage indi-

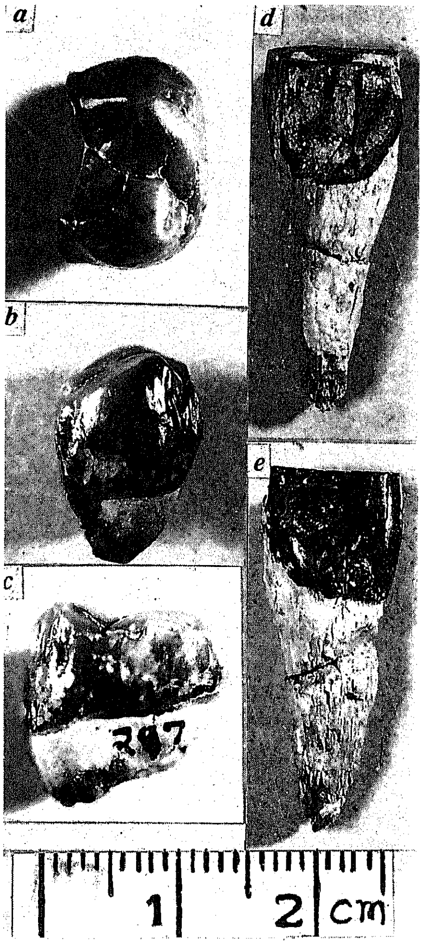

Figure 2. Hominid teeth from Ramchand *Sivapithecus* sp. (No. JVF/297), last lower left molar showing crown (*a*), lingual (*b*) and anterior (*c*) views. *Dryopithecus* sp. (No. JVF/518), upper incisor tooth showing internal (*d*) and external (*e*) views.

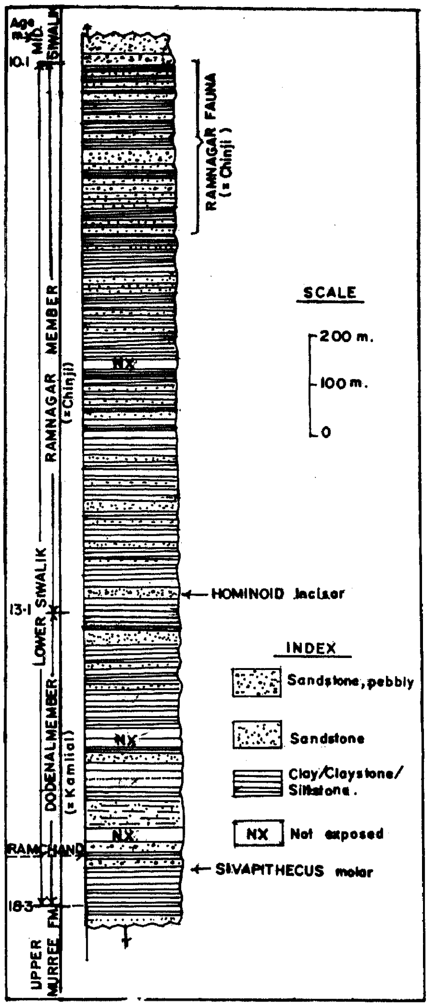

Figure 3. Lithocolumn along Ramchand–Ramnagar section showing stratigraphic position of the hominid teeth.

cates a Burdigalian affinity as well. In fact the approximate 18 m.y. datum for hominid existence in the Siwalik region is within expectations[9] and supports the earlier view of Andrews and Tobein[10] that the initial hominid diversification took place 'outside Africa and probably in central Asia'. The evolved character of the present *Sivapithecus* molar also indicates the pre-existence of its ancestral stock in Murree times as well and further suggests the Siwalik region to be the probable centre of hominid diversification and radiation. Further work, currently in progress in the area, is likely to substantiate the present find.

Ultrastructural evaluation, an useful method for fish leucocyte identification

Clarias batrachus is an air-breathing fish inhabiting unhygienic hypoxic waters of the swamp. Because of its air-breathing habit and survival in hypoxic water it is used as one of the model species for aquaculture in swampy water. Routine differential blood count reflects the pathophysiological status of the fish in culture. Sometimes difficulty was encountered in differentiating various leucocyte types by light microscopy[1–3] and scanning electron microscopy[4,5]. Identification of leucocytes at ultrastructural level is more authentic[6] and therefore, forms the basis of the present report.

Live specimens of *C. batrachus* (62 g) were cold anaesthetized[7] and blood samples were obtained in heparinized micro-haematocrit tube from the caudal vein and centrifuged at 1000 *g* for 30 min to sediment the leucocytes. The plasma of the haematocrit tube was carefully removed and replaced by chilled (4°C) 1.5% phosphate buffered (pH 7.4) glutaraldehyde for preliminary fixation of the packed mass of the leucocytes. After 1 h, the fixative (1.5% phosphate-buffered glutaraldehyde) was removed and replaced by 1% phosphate-buffered (pH 7.4) osmium tetraoxide at 4°C for 2 h. After 2 h the buffy coat of the packed leucocyte mass was sufficiently hardened to be removed from the micro-haematocrit tube, dehydrated in ascending concentrations of ethanol and acetone, cleared in toluene and embedded in araldite. Ultrathin (60–90 nm) sections obtained through Reichert Jung Supernova Ultramicrotome were transferred to copper grids and stained in uranyl acetate and lead citrate and viewed under Philips EM-10 transmission electron microscope at SIC-EM facility, AIIMS, New Delhi.

A merz grid of known dimension was projected over the transmission electron micrographs to estimate the surface volume ratios of the various leucocytes.

Lymphocytes, thrombocytes and granulocytes were the three distinct types of leucocytes identified in the section. The lymphocytes are the smallest (cross sectional area – 4.79 μm^2) and the most abundant leucocytes discernible in the section (Figure 1 *a*). The large clefted nucleus (3.55 μm^2) occupies nearly 74% of the entire interior of the cell and is surrounded only by a thin (1.24 μm^2) rim of cytoplasm. The nucleus–cell (N/C) ratio was very high (0.74). The surface/volume ratios of each leucocyte and its nucleus were 0.865 and 1.2 respectively. The nuclear chromatin was abundantly distributed on the periphery and the central part of the nucleoplasm. These ultrastructural

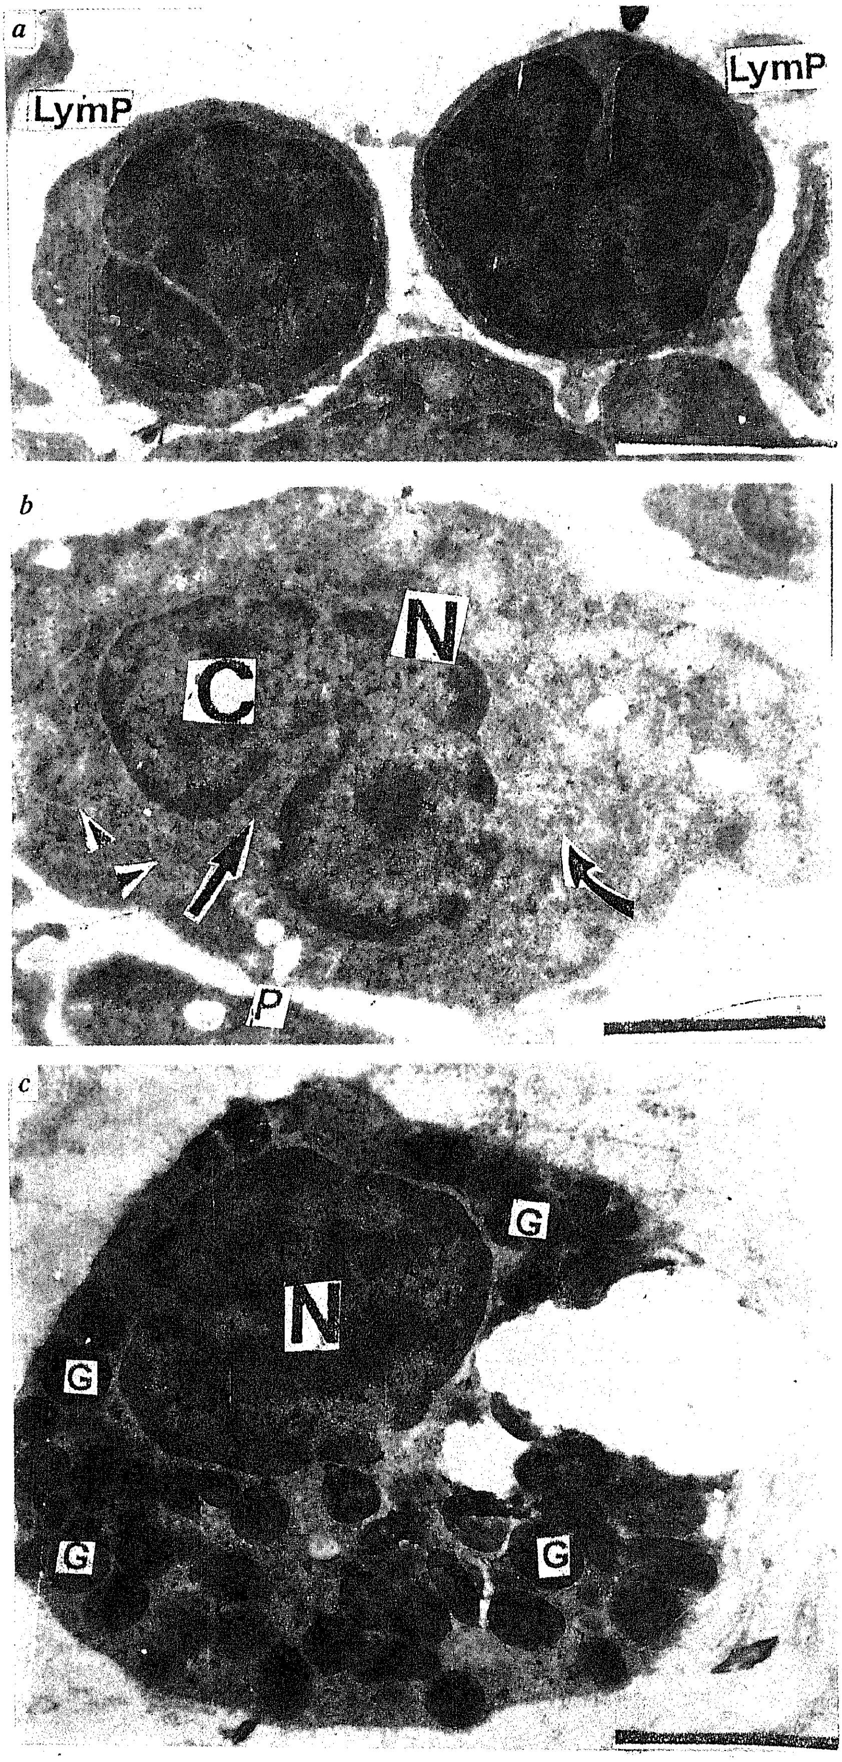

Figure 1 *a–c*. *a*, Transmission electron micrographs of the packed leucocyte showing lymphocytes (Lymp), bar = 1.33 µm. *b*, TEM of the fusiform thrombocyte showing chromatic (C), nuclear pore (arrow) of the nucleus (N). Pinocytic vesicles (P), electron dense material-filled vacuoles (curved arrow) and microtubules (arrowheads) are also seen, bar = 1.33 µm. *c*, TEM of granulocyte showing nucleus (N) and osmiophilic granules (G), bar = 1.33 µm.

details will be useful in identifying lymphocytes in the leucocyte sections of fish. The lymphocytes are important leucocytes with immunoglobulin (I_g) molecules on their surface membrane[8]. To the contrary of the high percentage of lymphocytes only a few thrombocytes were discernible in the leucocyte section of the air-breathing catfish. Each elongated fusiform thrombocyte was characterized by clefted nucleus (Figure 1 *b*) and its large size (18.07 μm^2). The nucleus (5.21 μm^2) occupies about 29% of the total cellular cross section with comparatively small (N/C) ratio (0.29). The surface/volume ratios of the cell and the nucleus were 0.50 and 0.93 respectively. Nuclear pores were clearly discernible in the nuclear membrane. The denser chromatin granules were mostly distributed on the periphery of the nucleus. However, centrally placed chromatin patches in the nucleoplasm were also seen. Presence of microtubules, clear vacuoles and vesicles full of osmiophilic granules were the other features of thrombocytes of the catfish in question. Each vesicle contains electron dense material similar to that of cytoplasm. Such vesicles loaded with secretory granules indicate their secretory nature. The granulocytes are larger (19 μm^2) with eccentrically placed nucleus (4.78 μm^2) and large number of osmiophilic granules of varied dimensions ($0.46 \pm 0.12\ \mu m^2$). The N/C ratio was comparatively smaller (0.25). Denser nuclear chromatin was more patchy in distribution. The cytoplasm was packed with numerous large, round to elongated osmiophilic granules (Figure 1 *c*). The surface/volume ratios of the cell and the nucleus were 0.42 and 0.88 respectively.

Plant life under extreme environments

H. Y. Mohan Ram and Promila Gupta

There is no habitat in the world where some plant or the other will not grow provided there is some moisture and light[1]. It is the energy provided by these plants that sustains the life of all heterotrophic organisms. Plants cannot tolerate excessively high temperatures like some of the bacteria and fungi, but do occur under extremely hostile surroundings such as mountain tops, hot and cold deserts, water-logged conditions, coastal habitats, metalliferous soils and spoil heaps of old mines. Plant life of the arctic is highly specialized with an antiquity dating back to at least 2 million years[2]. The knowledge of the survival strategies should assist humans to learn the secrets of balance, productivity and sustainability and as references against which we compare areas which we have developed[3]. Even for our own survival and that of the future generations, understanding of the nature of the stress-tolerant genes and their introduction into agricultural, horticultural and forestry species either through conventional breeding or genetic engineering would be important.

A vast amount of literature exists on the adaptation of plants to extreme environmental conditions. This pictorial article essentially deals with natural history. Certain leads in ecology and physiology have been indicated; aspects dealing with pollution and biotic stresses are not covered.

Plant life in deserts

Deserts are hot or cold, often sand-covered lands receiving below 125 mm annual rainfall. Their soils are dry with abundant soluble minerals and scanty vegetation. Humans have learnt to overcome the perils of desert existence by finding sources of water, food and shelter. Deserts also provide some of the world's most awe-inspiring scenery with a spectrum of moods and quiet mystery. Roughly one seventh of the globe's surface is occupied by deserts.

Water is necessary and convenient for all life and is a molecule of common occurrence. Plants have an extensive root system which absorbs both water and minerals. Ditmer (cited in ref. 4) of the Iowa State University has made the astounding finding that the total length of roots (minus root hairs) formed by a single rye plant in a period of four months is 387 miles, covering a total surface area of 2554 sq. ft.! Plants lose large amount of water in transpiration through minute openings in the shoot called stomata, sometimes in excess of the quantity absorbed. If the stomata close down to check water loss, the plants would starve as they are the gateways for entry of carbon dioxide, the important raw material for photosynthesis. In evolutionary terms, transpiration is an unavoidable evil of plant life. Thus conservation of water and its usage is one of the greatest challenges faced by desert plants. Plants inhabiting deserts are termed xerophytes (xerophiles) and are further categorized by Levitt[5] as evaders, avoiders and tolerant plants. Plants occurring in hot deserts are slow-growing and may suffer mechanical or metabolic form of drought injury[6]. The latter is manifested in the form of decreased photosynthesis, protein metabolism and membrane permeability.

As availability of water is restricted in most deserts, at times only to a few days, evaders have to complete seed germination, establishment of plant, flowering and seed set in a brief span. After one or two showers, the parched soil turns green and the splendour of flowering is spread over the entire desert. The evaders are thus ephemerals that pass the rest of the year as seed. The avoiders have special structural modifications to reduce water loss. These include a thick outer layer (the epidermis), sunken stomata, waxy coating, rolling of leaves during drought, reduction in size or absence of leaves or their early detachment. In plants such as *Euphorbia caducifolia* of the Thar desert, *Fouquieria splendens* and *Opuntia* sp. of the Sonoran desert, the stem turns green to carry on photosynthesis.

Table 1 shows the enormous extent of root development in a few desert plants. In plants such as *Aqave salmiana*, the root to shoot ratio is low. In older perennials and shrubs of the Great Basin, Turkestan and some other deserts, it ranges from 1 to 9 (refs 7, 8).

A common morphological feature of desert plants is succulence of the above ground parts. Succulents occur in several distant and unrelated families such as Aizoaceae, Chenopodiaceae, Cactaceae, Crassulaceae, Euphorbiaceae, Asclepiadaceae, Liliaceae and Amaryllidaceae. This leads to the confusion between succulents and cacti and strictly speaking the latter belong to the Cactaceae. All the cacti are of New World origin,

This article is based on a lecture delivered by H.Y.M. at Jodhpur on 2 November 1996 during the 62nd Annual Meeting of the Indian Academy of Sciences. We pay homage to all the plant scientists of the Central Arid Zone Research Institute, University of Jodhpur, notably Professor M. M Bhandari and the Botanical Survery of India Arid Zone Circle, Jodhpur, who have enriched our understanding of plant life in the Thar Desert.

Table 1. Extent of root penetration of a few representative plants growing in different deserts

Genus	Location	Root penetration (m)		Source
Alhagi	Asian desert	Depth	25	Daubenmire (1959)
Glycyrrhiza	Asian desert	Depth	15	Daubenmire (1959)
Andina	Brazalian desert	Depth	19	Daubenmire (1959)
Prosopis	Arizonian desert	Depth	20	Daubenmire (1959)
Tamarix	Saharan desert	Radius	40	Ladover (1928)
Larrea	Saharan desert	Radius	27	Ladover (1938)

although they have been introduced to the other continents where some have run wild. Succulents are able to absorb huge amounts of water during a heavy rain and store it for a long time. The saguaro cactus (*Carnegia gigantea*) of the Sonoran desert reaches a height of 15 m, lives for 150–200 years and weighs 9–10 tons[9]. Its shallow, wide-ranging roots and the surface of the fluted stem can gather as much as one ton of water after one or two bouts of rain. Additionally in some succulents, the stomata close during the day to prevent evaporation and open only during the night. Carbon dioxide is fixed in the dark in the form of carboxylic acids, which are converted into carbohydrates during the day. Such plants are called CAM (Crassulacean Acid Metabolism) plants.

The truly drought-tolerant plants are those which have the capacity to stand dehydration for prolonged periods without succumbing to it. Lichens, mosses, ferns and a few seed plants are included under this category. They are collectively called resurrection plants. A common example is *Selaginella* sp. sold as a curiosity at holy places in North India. The dried and curled-up plants turn green after a few hours of soaking in water. Among the most dramatic examples of resurrection plants are creosote bush – *Larrea divaricata, Carex physoides, Ramonda nathaliae, Myrothamnus flabellifolia, Chamaegigas intrepidus.* These stay glued to the soil almost appearing dead and dry, turning green and reviving even after one rain. They start respiring within 48-60 hours and begin to photosynthesize thereafter. The rose of Jericho (*Anastatica hierochuntica*) is unusual, as the dry plant rolls up and is blown around by wind. When it starts raining the plants recover, become stabilized and continue to grow.

The creosote bush produces chemicals that smell like coal tar in its shoot to dissuade browsing animals. Its roots also secrete certain substances (allelopathic chemicals) that inhibit the roots of other plants in the vicinity. The plant collects moisture from the dew or in case of an exceptional rain by sending out underground stems with mats of tiny roots to absorb every drop of water percolated into the soil. Another bizarre plant that has an amazing capacity to survive for over 1000 years in perennially arid conditions of the Namib desert is the gymnosperm *Welwitschia.* It is also endowed with the ability to collect dew from the air.

Sand-dunes are by far the most common habitats of the arid deserts. The dunes are formed by strong winds that carry the sand particles and pile them into mounds. Some dunes are stabilized, others partially stabilized or unstabilized and barren. Several herbaceous grasses, amaranths, legumes, cucurbits and asclepiads cover the sand by striking roots at nodes. The most common shrubs of the dunes in the Thar desert are *Calligonum polygonoides* (an excellent source of charcoal), *Commiphora wightii* (guggul), *Clerodendrum phlomidis, Haloxylon salicornicum, Lycium barbatum* and trees such as *Prosopis cineraria, Salvadora oleoides* and *Acacia senegal.* These provide food, feed, shelter or other materials for animals and people[9a].

Some herbaceous plants surviving cold stress in the frozen arctic region have flowers which show solar tracking; for example *Dryas octopetela, Papaver radicatum* and *Ranunculus glacialis.* The petals reflect the warmth of the sun's rays towards the centre of the flower to increase the temperatures to attract the pollinating insects[1]. The cushion habit plants such as dwarf azalea (*Loiseleuria procumbens*) and dwarf campion (*Silene acaulis*) in the cold deserts increase the inner temperature by 15°C above the ambient temperature[10] and also humidity. These plants have the unusual capability of making a net carbon gain for the entire year in a brief growing season, complete development and reproductive cycle with minimal thermal input[1]. As they cannot invest sufficient material for sexual reproduction, they turn to vegetative propagation[11]. Shivaji and Ray[11a] have reviewed the survival strategies of microorganisms adapted to extreme cold conditions prevailing in Antarctica.

Salinity

Very often the aridity caused by low rainfall and extremely high or low temperatures are compounded by high salinity in the soil, resulting in severe problems in absorption of water and curtailing productivity. Plants that survive high salinity are called halophytes. Among these, members of family Chenopodiaceae, especially the species of *Atriplex* are notorious. Collectively called the saltbush, the species of *Atriplex* show accumulation of ions against concentration gradient. Plants such as *Suaeda, Salsola, Kochia, Haloxylon, Portulaca, Cressa, Sesuvium* and *Tamarix* commonly occur in the Thar desert. Some species have the ability to store and secrete salt through special glands on the leaf surface. Additionally, in the ice-plant *Mesembryanthemum crystallinum,* a native of the Namib desert, the presence of salt secreted on the surface enables absorption of moisture from the humid air.

Several useful species of *Atriplex* have been introduced to India for cultivation on saline soils for meeting fodder and fuel requirements and also for stabilizing mineral soils. As a result of heavy irrigation and poor drainage, many parts in India have been experiencing increased salinity. It is common to see large patches of white crust of salt on the surface of the clayey soils containing sodium chloride and other salts in Haryana, Punjab, Rajasthan and Western UP. Many crops are sensitive to salt whereas a few are moderately tolerant. The distribution of wild relatives of cultivated plants in the saline soils as well as varieties of rice that are salt tolerant and the mechanism of salt tolerance have lately become important aspects of agricultural research. An increase in root to shoot ratio has also been reported in response to salt stress[12,13].

Mangroves and plants of salt marshes

Plants that inhabit coastal regions and estuaries and have become adapted to survive under inundated salt water conditions constitute the mangrove vegetation. Some are viviparous and shed their germinated fruits in tidal waters to facilitate their establishment. Physiologically mangroves not only face the problem of absorption of water from highly saline conditions but suffer from insufficiency of oxygen in their roots. The angiospermous mangroves and swamp cypress (*Taxodium distichum*) produce characteristic vertical roots which grow in a negatively geotropic manner above the water level and serve the purpose of aeration (pneumatophores). Mangroves are ecologically important as they prevent coastal erosion. There has been a severe destruction of mangroves, on account of the valuable firewood and tannins they yield.

Coconut is among the most useful plants which is highly salt-tolerant. *Casuarina equisetifolia* and other species of *Casuarina* were introduced to India from Australia primarily for checking coastal erosion. They are presently grown even inland as fast-growing trees, capable of fixing atmospheric nitrogen with the association of *Frankia.* As the wood can be burnt even when still green, it is used as an important source of firewood. Herbaceous plants with excellent coastal sand-binding properties include *Ipomoea aquatica* and *Spinifex squarrosa.* The latter is being recommended for preventing coastal erosion in the Lakshadweep islands.

Aquatic plants

Water is essential for plant life but its over-abundance leads to several problems. This is particularly true of those plants in which photosynthetically active parts are submerged in water or float on the surface permanently or at least for several months each year[14]. About 2% of all the flowering plants known in the world live in water and more than 50% of these are represented in the Indian subcontinent[15]. Evolutionarily plants migrated from water to land. However, when the reverse process occurred, plants had to undergo a wide range of structural, physiological and biochemical changes. Notable modifications of aquatic plants include a poor root system, high reduction in mechanical tissues, development of large air spaces which interconnect the entire plant and a high propensity for vegetative propagation. Plants living in water and those subjected to flooding show different degrees of oxygen shortage[16]. Aquatic plants with floating leaves such as *Nymphaea* and the Indian lotus (*Nelumbo nucifera*) have rhizomes and roots buried in the anoxic sediments of shallow freshwater lakes. As oxygen supply by gaseous diffusion to the submerged parts is difficult, these plants have developed a pressurized diffusion system, also termed thermal transpiration (thermal osmosis). Addressing the French Academy in 1841, Raffeneau-Delile of the Faculty of Medicine at Montpellier, reported his curious observation of the escape of gases from partially submerged lotus leaves in Egypt. Since then, several other scientists have pursued the study of gas-flow through the air-space system in emergent water plants.

John Dacey, a doctoral student working at the Michigan State University on the flow-through ventilation system in the yellow water lily (*Nuphar advena* Ait = *N. lutea*) has been largely responsible for resurgence of interest in this study. Using sensitive GC analysis and by injecting ethane into the stalks of young leaves, Dacey[17] was able to demonstrate the downward movement of the gas into the rhizome and its escape through stomata in the older leaves. He noted that the heat absorbed by the young leaves (influx leaves) converts water into vapour, which is pushed downwards under pressure along with other gases through the intercellular spaces to their rhizome and their exit through the petioles and leaf blade of older leaves (efflux leaves) on the same rhizome branch (Figure 1). This process enables supply of oxygen to the roots, rhizomes and rhizosphere and the movement of respiratory carbon dioxide to the leaves for photosynthesis[17-19]. Dacey and Klug[20] also showed that these waterlily plants transferred methane gas formed by anaerobic methanogenic bacteria from lake sediments to the atmosphere. This mechanism has been shown to operate in other submerged plants for the supply of oxygen to parts below water[21,22] and has been aptly called the 'biological steam-engine'. In a recent review, Singh and Singh[23] have reviewed the role of plants such as *Typha* and rice in methane emission from the wetlands in India.

The Podostemaceae – A strange family of aquatic plants

A good deal of information is available on the stresses experienced by submerged, free-floating and emergent but rooted aquatic plants. There are gaps in our knowledge about a highly interesting family of flowering plants, the Podostemaceae. They occur almost exclusively under cataracts and fast-flowing rivers, submerged but firmly attached to rocks by means of rhizoids that secrete a gummy substance[24,25]. They have a thallus-like plant body that has no air spaces, unlike other water plants. Members of the sub-family Podostemoideae lack differentiation into root, stem and leaves and can be easily mistaken for algae, lichens or liverworts. Generally so long as the plants lie 20–25 cm below water, they never enter the flowering phase. However, a drop in water level causes initiation of flower buds. Flower opening, fruit and seed development require exposure to air. Thus sexual reproduction in these plants appears to be regulated by water stress. These aspects have been substantiated by experimentally grown plants in our laboratory.

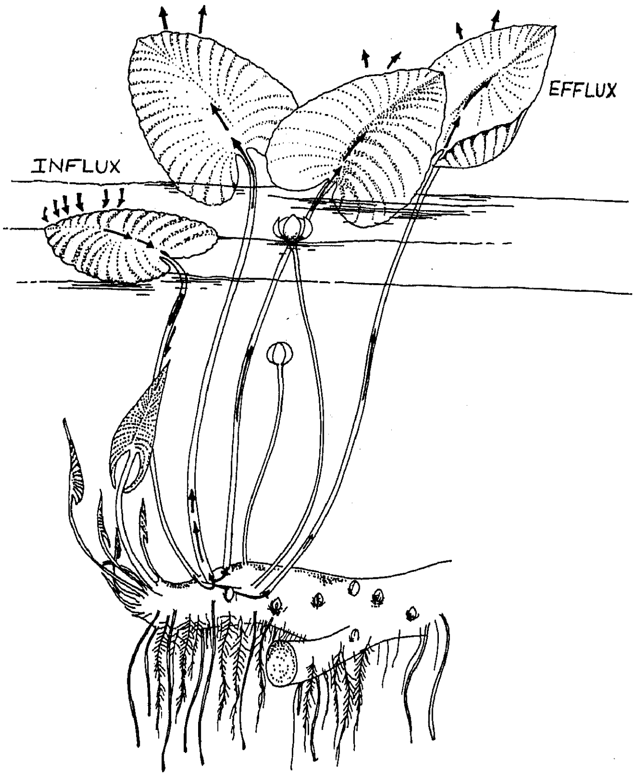

Figure 1. Ventilation in *Nuphar* advena, showing the path of the gas through flow (Drawn after Dacey).

Water logging and flooding

Most trees are sensitive to water logging. However, there are many exceptions such as the massive trees of the Amazonian forests adapted to tolerate flooding for several months. The mechanisms that support life under anaerobic conditions of these plants are being studied[16].

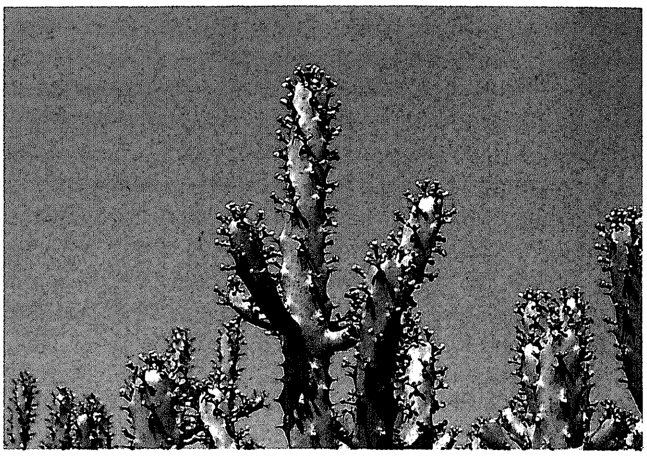
Certain deepwater rices are known to respond to flooding in late monsoon. They branch at the higher nodes, show rapid internodal elongation when submerged due to rise in the level of water and produce adventitious roots at the upper nodes. Submergence stimulates the synthesis of ethylene gas which helps in cell lengthening response to the hormone gibberellic acid[26]. Both cell division and cell elongation are responsible for the rapid stretching of rice plants (often 25 cm in one day) under flooded conditions[27]

Metallophytes

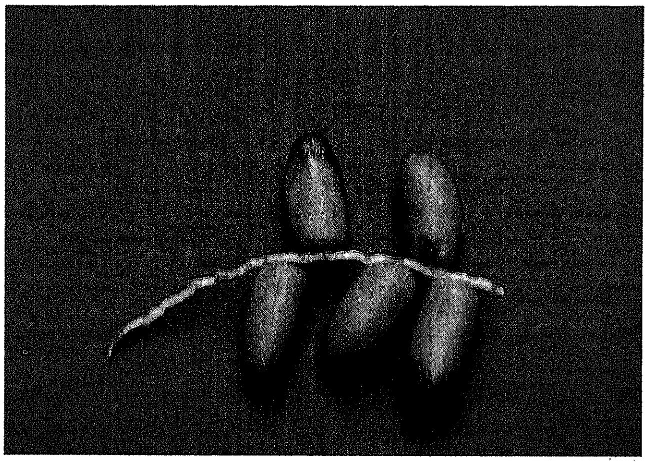
Certain elements are essential for all organisms; some are needed in relatively large amounts (macro or major elements) and others in small amounts (micro elements). Unlike animals, the majority of plants do not need sodium and iodine. Curiously plants accumulate a wide spectrum of non-essential elements at concentrations several hundred-fold higher than that in the soil or water. Barring drinking water and pollutants, all the essential minerals needed by animals and humans are derived directly or indirectly from plants. Ecologists have studied the types of vegetation occurring on metalliferous soils, mine-tailings and abandoned mines and have identified plant communities and populations of individual species growing on them. It is possible to associate indicator species that reflect the concentration of a metal in the soil. This interesting branch of science termed geobotany, has been helpful in prospecting for minerals and also in bioremediation and recovery of contaminated soils to productive lands.

Baker and Walker[28] have classified plants that grow on metalliferous soils into three groups: (i) Metal-excluders – those that accumulate large amounts of metal(s) in their roots but prevent their translocation to the shoot. (ii) Indicators – which contain metals both in root and shoot but reflect the levels of metal present in the soil. (iii) Hyperaccumulators – species which con-

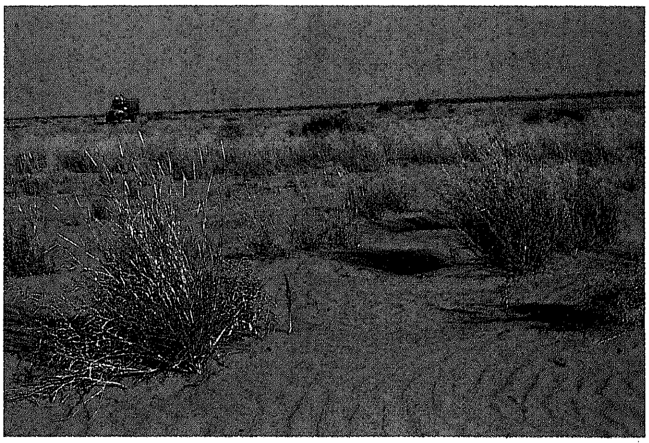
A close-up of the female inflorescence of the date palm *Phoenix dactylifera*. The palm is hardly and grows near oasis in the Central Asian deserts with 'feet in water and head in fire'.



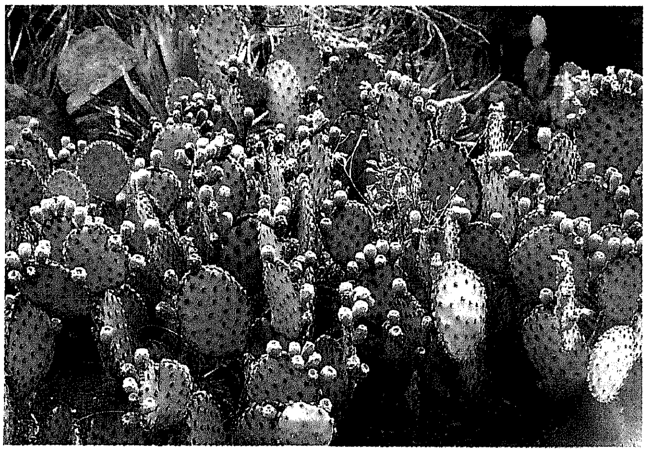
A close-up of *Euphorbia caducifolia* of the Thar desert. The green stem is photosynthetic and contains a milky latex. Many succulents are erroneously called cacti. (H. Y. Mohan Ram).



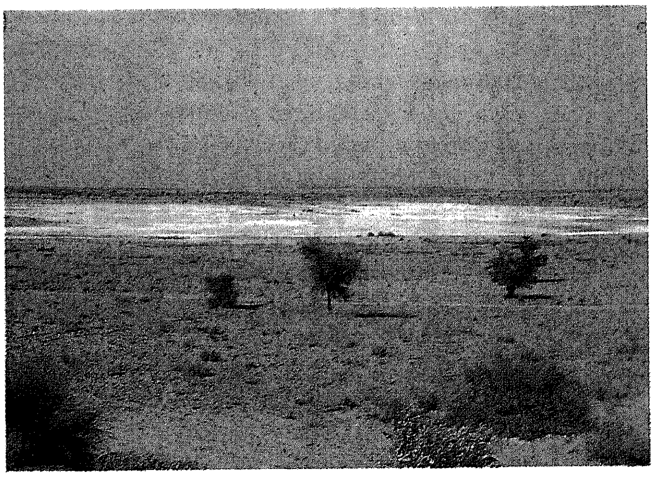
Mature fruits of date, eaten fresh or dried. Before the oil boom, date was an important item of trade in Middle East. (H. Y. Mohan Ram).



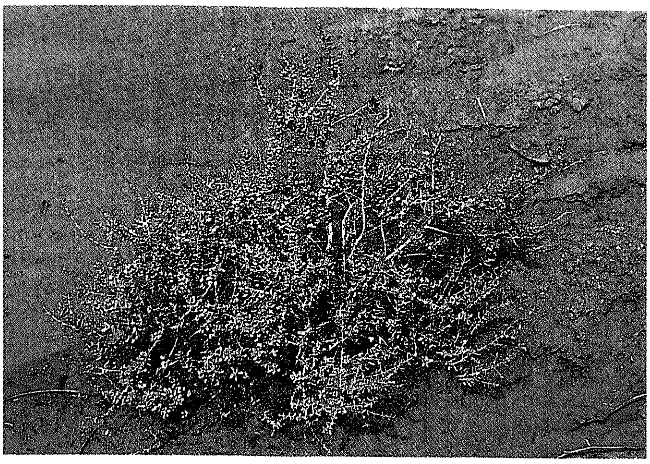
Ferrocactus wislizerii, the fish hook barrel cactus from Arizona USA, with orange flowers. Browsing animals are kept away. (H. Y. Mohan Ram).



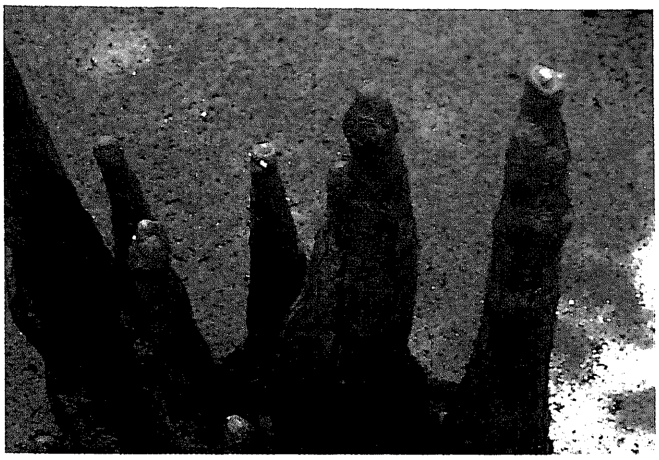
Opuntia or prickly pear of the Sonoran desert in N. America (this particular species has no barbed bristles). A leafless succulent, it stores water in the tissues and can tolerate 60°C for a few hours. (H. Y. Mohan Ram).



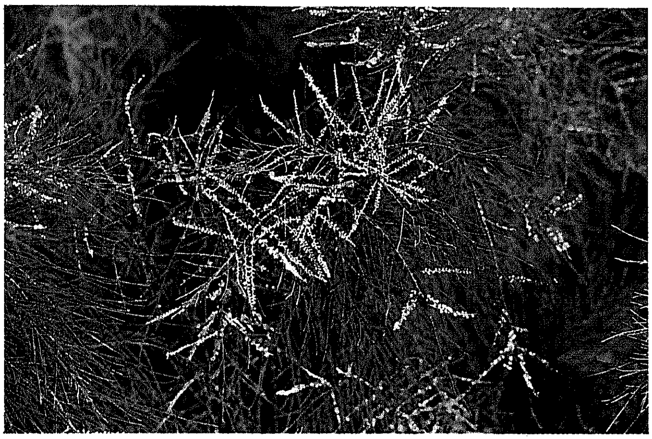
Suratgarh, Rajasthan. Salt deposition on the soil caused by rise in water table due to irrigation. (M. M. Bhandari).



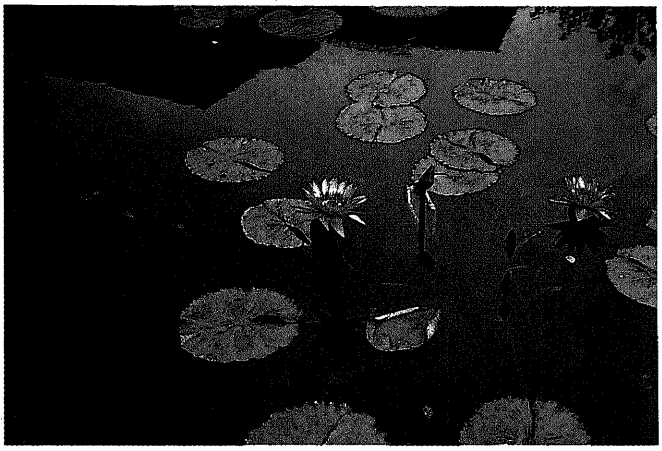
Suade fructicosa a greyish-green, herbaceous halophyte of the Thar desert, it has an extensive root system. (M. M. Bhandari).



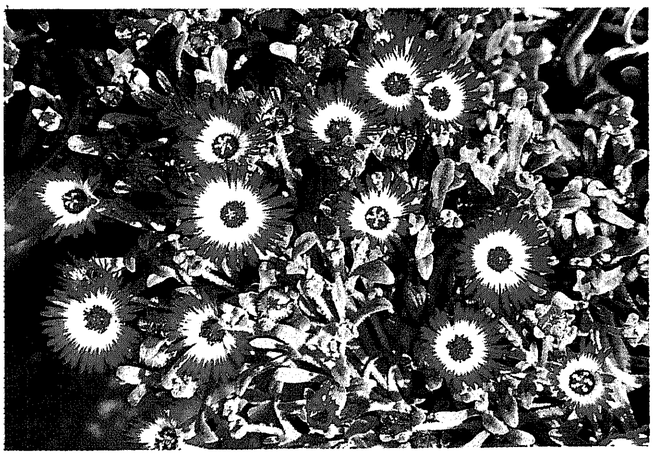
Pneumatophores of swamp cypress. Some of the roots grow vertically above water and assist in gaseous exchange. (H. Y. Mohan Ram).



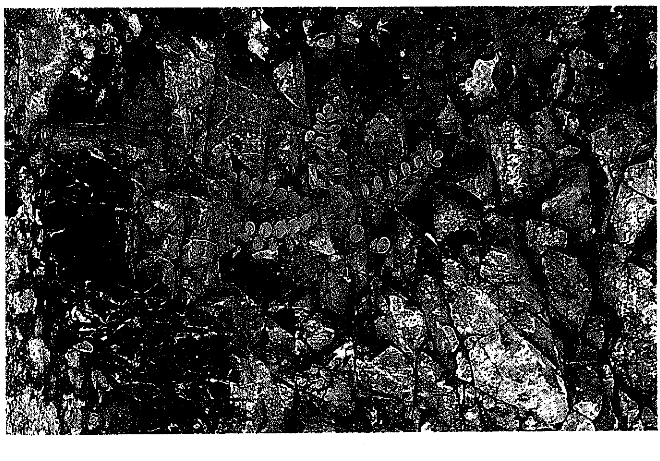
Tamarix sp. A typical plant of the salt rich soils of Thar desert, it has an extensive root system. (M. M. Bhandari).



Nymphaea, a rooted aquatic plant with floating leaves and beautiful flowers has a 'steam engine' mechanism for aerating the buried rhizomes. (H. Y. Mohan Ram).

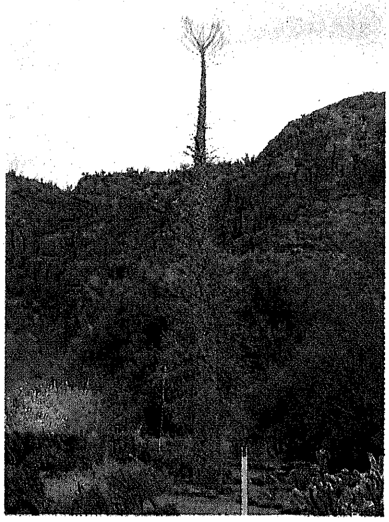


The ice plant, a native of the Namib desert in South Africa is now grown throughout the world as an ornamental. The surface of the plant has vesicles looking like ice crystals. The secreted salt helps in the absorption of moisture in the air. (Rajesh Tandon).

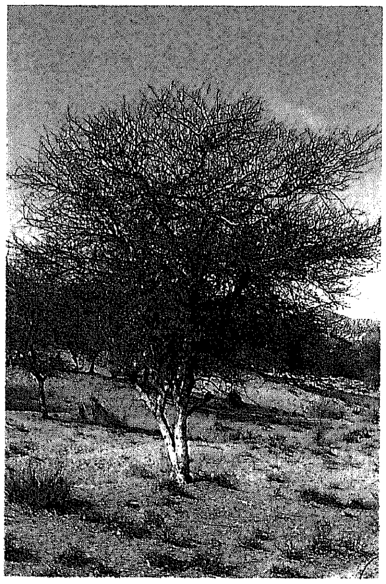


Astragalus graveolens, a leguminous weed established on a limestone quarry by scientists of the University of Delhi. Seeds embedded in sodium alginate along with the symboitic nitrogen fixing bacterium *Rhizobium* are used for reclamation. (Anupam Joshi).

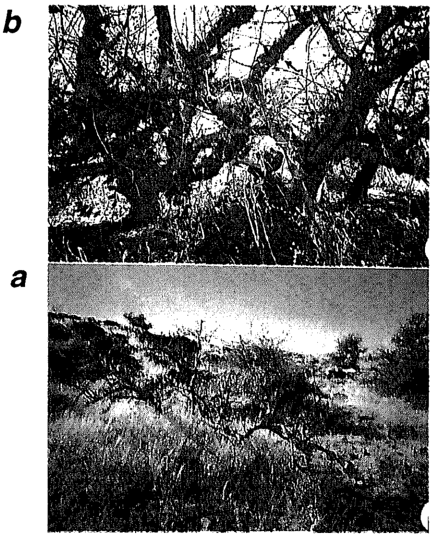
Spinifex squarrosa, a trailing grass, effective as a sand binder along the southern sea coasts of India. It is popularly called Ravana's whiskers on account of the stiff, sharp leaves. (Pratibha Pande).



The boojam tree (*Idira columnaris*) of Arizona, USA. It gives the impression of being upside down. (H. Y. Mohan Ram).



Kurrta. *Acacia senegal* is the source of gum arabic. The tree yields fodder, edible seeds and firewood. (Rajesh Tandon).



a. A rocky slope with thorny vegetation near Jodhpur. In the foreground is seen the innocuous, leafless shrub of guggul, amidst dry grass. ***b.*** A portion enlarged to show the tangled mass of branches of the shrub. The yellowish resin produced by incising the stem dries up into a brown mass. Guggul is an ancient Indian drug and its hypolipidaemic, hypocholestrolemic and antiarthritic effects have been reestablished by Indian scientists. 'Guglip' is presently sold in the market. The plant is threatened by over-exploitation.

centrate metals in the above ground parts, far in excess of that is present in the soil. Among the hyperaccumulators, those that take up heavy metals from soil are of tremendous importance. They have attracted attention for understanding the ecophysiological mechanisms and importantly the genetic basis of their endowment[29].

On a dry weight basis, hyperaccumulators may contain 0.1% of Ni, Co, Cu and Cr and Pb or 1% of Zn in their leaves. Tiagi and Aery[29a], working at the Udaipur University have studied the zinc deposits at the Zawar mines. They have noted that the balsam plant (*Impatiens balsamina*) and *Triumfetta pentandra* constitute an important vegetational unit. In the Rajpura–Dariba zinc bearing belt, *Kickxia ramosissima* and *Bidens biternata* show the highest constancy and fidelity on these soils.

The list of hyperaccumulating plants is growing steadily. Among these, species of the Brassicaceae (Cruciferae or the mustard family) are predominant in the temperate regions whereas the Euphorbiaceae represent their counterpart in the tropics[30]. Baker and coworkers[31] have reported that the Caledonian tree *Sebertia acuminata* has more than 11% of Ni in its latex on a dry-weight basis.

When hyperaccumulators enter the food chain through browsing wild animals or domestic livestock or poultry, there are chances of reaching acute toxicity levels in them as well as in humans. The classical examples of this condition are selenium-accumulating species of *Atriplex* and *Haplopappus*. Selenium replaces sulphur in the amino acids cysteine and methionine, resulting in various disorders in humans and livestock. 'Blind staggers' is a condition caused by excess selenium in livestock, consuming 100–1000 ppm in the forage. It results in impairment of vision, weakness of limbs and respiratory failure. Cattle and horses feeding on plants containing 25 ppm of selenium, suffer from 'alkali disease' with symptoms such as lack of vitality, loss of hair, sterility, atrophy of hooves, lameness and anaemia[32].

The copper flower (*Haumaniastrum katangense*), a common weed in the world's richest Zaire copper and cobalt belt in Central Africa, is a classical example which contains more than 0.1% of Co or Cu in the dried leaf-tissue.

Several scientists including botanists have a prejudiced view of the utility of a herbarium. Besides serving as a systematically arranged repository of dried plants, (authentic representatives of described and named species) a herbarium serves many other important functions. Recently pieces of leaves removed from herbarium specimens have indicated the amounts of heavy metals accumulated by plants 10–200 years ago from specific sites, thanks to sensitive methods of analysis. It is possible to judge the fluctuating levels of certain metals as well as levels of pollution over any given period of time by comparing the values in live plants with those in preserved plants of the past.

Mechanisms

The enormous biodiversity that exists in plants underlines their ability to adapt themselves to a wide spectrum of environmental conditions, as narrated above. Whether it is drought, cold, salt or metal stress or a combination of some or all of these, the end result is a dehydration stress. As early as 1958, Levitt[33] speculated that plants may have a general mechanism of resistance to every stress. At the morphological level wilting, leaf rolling and decrease in stomatal aperture, succulence, leaflessness, etc. constitute a general mechanism for conserving water[34]. At the physiological level, reduction in evapotranspiration and decrease in water potential are major manifestations.

How do plants sense stress signals?

There has been a revival in the study of signal communication in plants[35]. For example, how do roots perceive water stress and transmit the signal to the shoot to cause stomatal closure? The chemical communication with stress hormone abscisic acid (ABA) requires transcription and translation and hence is a slow process requiring at least two hours. The electrical signal (action potential) is rapid and acts in seconds. However, conduction of electrical signals has some limitations where long distances are concerned[35]. We are also in the dark regarding signals which transmit other stresses such as cold, salinity or high metal concentrations.

Stress- induced chemicals

Biochemical studies have revealed similarities in processes induced by various abiological stresses, leading to accumulation in plant tissues of compounds such as ascorbate, glutathione, α-tocopherol, betaine, proline and other amino acids, quaternary ammonium compounds, polyamines, sucrose, polyols (mannitol, sorbitol, pinitol) and oligosaccharides[36]. Additionally changes in the activity of certain key enzymes, gene expression and biosynthesis of ABA have also been noted.

Plants have developed mechanisms to prevent toxic effects of heavy metals on their metabolism. Many plants compartmentalize ions by storing them in their vacuoles. Inside the vacuoles, they may be chelated by citric or malic acid and rendered inactive. Recently certain polypeptides with the general formula γ(Glu–cys)*n*-Gly (where n = 2–11) have been identified in plants. These compounds termed phytochelatins or metallochelatins are believed to be induced by a specific metal. There is some evidence that as in animals, in plants also, there are genes that code for metallothionein-like proteins[37] but these are synthesized mainly in response to heavy metals[38–40].

Role of heat shock proteins in thermotolerance

Unlike certain archaea (such as *Methanococcus jannaschii*) and fungi which have the unusual propensity to survive and function normally under temperatures in the range of 80–100°C, most flowering plants are unable to stand temperatures above 50°C. The prickly pear (*Opuntia* sp.) occurring in the deserts of North America is shown to tolerate 60°C for a few hours. The role of heat shock proteins (HSPs) in thermotolerance of crop plants has been recently reviewed by Viswanathan and Khanna-Chopra[41]. These authors have also discussed the various heat-avoidance mechanisms which are significant in production of crops, specially those grown in the tropical and sub-tropical countries. That heat shock proteins are induced as a result of newly transcribed mRNA is universally accepted in a wide range of organisms[41–45]. This unique response was first reported in the fruit fly *Drosophila melanogaster*, where the heat-induced chromosome puffing was followed by a high-level expression of HSPs[42]. The synthesis of these proteins leads to acquired thermotolerance.

There is increasing interest in the identification of genes and their products that regulate tolerance to physical stresses in plants. This topic was discussed in depth at a workshop entitled 'Physical stresses in plants' held in Maratea, Italy[46].

Dehydrins

During the long course of evolution, several groups of plants have attempted to develop the seed habit but successful seed plants have been recorded from the upper Devonian, approximately 345 million years ago[47]. There is no structure equivalent to a seed in the entire animal world. Generally, seeds result from sexual reproduction in gymnosperms and flowering plants, capable of developing into a new individual. A seed that contains an embryo, stored food and protective coverings represents suspended animation as it is neither the beginning nor the end of plant growth. Unlike the vertebrate embryo which upon maturity develops into a young individual, in a seed all growth ceases for a brief or a prolonged period of time. A unique feature of most seeds is that they show a high degree of desiccation even though the surrounding parts may have abundant moisture as in watermelon, tomato or lotus. Seeds are known for their longevity and viability even under extremely severe environmental conditions. The most well-studied is the lotus seed, estimated to retain its germinability even after 1000 years[48]. Seeds of the arctic lupin (*Lupinus arcticus*) collected from a hemming burrough in the Yukon province of Alaska are estimated to retain viability even after 10,000 years, although some scientists are doubtful about this claim[48].

Understandably there has been a tremendous amount of interest in finding the mechanism by which mature embryos are protected from excessive dehydration to survive long periods of time and come back to life and establish plants when conditions become favourable for germination. In this context the discovery of dehydrins has been of special significance. The term dehydrin is synonymous with 'Late Embryogenesis Abundant' proteins designated as belonging to the LEA D-11 family. These were initially identified in investigations made on proteins and mRNA populations during the maturity of cotyledons of the cotton plant and subsequently in barley, rice, oil seed rape and wheat[49,50]. In mature embryos, they may reach levels in excess of 1% of total soluble proteins[51]. The LEA proteins can also be induced by ABA in zygotic as well as somatic embryos[52]. According to Close[34] dehydrins are the most conspicuous of soluble proteins which are formed in response to drought, cold, salinity stresses and also during normal seed maturation. They range in size from 9 kDa to 200 kDa without showing resemblance to any known enzyme sequence[53,54].

Xu *et al.*[55] have studied the expression of a LEA protein gene *HVA 1* from barley (*Hordeum vulgare*) and have observed that it confers tolerance to water deficit and salt stress in transgenic rice when this gene is introduced. Some LEA proteins when present alone are not sufficient to confer desiccation tolerance but require the presence of other solutes like sugars to be effective[56–58].

Phytoremediation

Phytoremediation is a new technology employed for removing excessive toxic metals and pollutants from soils or contaminated aqueous medium. Kaizer Jamil[59] has shown that water hyacinth can accumulate large amounts of Hg, Cd, Zn, Pb and Cr from solution containing salts of these elements. Ozimek[60] has demonstrated the ability of several aquatic plants to cycle heavy metals from sewage waste. Both algae and large flowering water plants such as water hyacinth and *Phragmites* are being used for removal of heavy metals from contaminated waters. It is believed that bioremediation with the use of specific plants is a relatively inexpensive operation. It is also possible to recover heavy metals by incineration.

Heavy industrialization, uncontrolled discharge of factory effluents from smelting, electroplating and leather industries, emission of organic lead in the atmosphere from automobile exhaust are causing accumulation of dangerous amounts of metals in our environment. The possibilities of a cleaner and greener planet by using plants and employing methods which are simple, safe and dependable, are keenly awaited.

ACKNOWLEDGEMENTS. We thank Drs V. R. Sashidhar, Meenakshi Sethi, Anita Sehgal, Renu Khanna-Chopra and Professors S. K. Sinha, P. S. Ganapathy, C. R. Babu, M. M. Bhandari and Ishwar Prakash for stimulating discussions in preparing this text. We are indebted to Professor M. M. Bhandari, Dr Prem Uniyal, Mr Anupam Joshi, Mr Rajesh Tandon and Ms Pratibha Pande for providing some of the colour pictures used in this article.

Bacterial ice nucleation: Prospects and perspectives

P. Pattnaik, V. K. Batish, Sunita Grover and Niyaz Ahmed

In this new emerging era of biotechnology, ice nucleating proteins find varied applications in different fields like artificial snow making, freeze texturization of foods, freeze drying, freeze concentration, detection of bacterial pathogens and also in the control of frost damage to plants. However, the commercial exploitation of this novel biobased and energy saving technology is still under consideration.

BIOLOGICAL systems to initiate a physical process are not new to man. Perhaps the best characterized biological indicators are bacterial ice nuclei, which trigger crystallization of ice in super-cooled water. Detailed characterization of ice nuclei has been carried out in certain bacteria of plant epiphytic communities like *Pseudomonas syringae, P. fluorescens, P. viridiflava, P. coronafasciens, Erwinia herbicola, E. ananas, E. uredovora, E. corotovora, Xanthomonas campestris* and *X. translucens*. In all the strains investigated so far, the phenotype is encoded by a single gene[1–5]. The product of this gene expression is a membrane-bound protein. This protein, alone or in combination with membrane phospholipids, mimics the structure of an ice nucleus and thus, acts as a template for ice formation which is responsible for imparting ice nucleating activity to the bacterium. Such bacteria are referred to as ice-plus (ice$^+$) or ice nucleation active (INA) bacteria.

Ice used in daily life is created either due to ice nucleators or due to secondary nucleation. Ice and water can co-exist in equilibrium at 0°C provided heat is neither added nor removed. Removal of heat causes water to convert to ice without need of nucleation. The system becomes totally solid, maintaining a temperature of 0°C. But, when ice is initially absent in the system, solidification follows a different path. When primary nucleation proceeds to crystal growth upon cooling, the temperature of the system falls below freezing point, called super cooling, before nucleation. Nucleation is a necessary step in order to surmount an energy barrier (activation energy) before water converts to ice. Thus, nucleation can be defined as a process that generates within the supercooled state of water (metastable mother phase), the initial fragment of a more stable phases. These fragments then spontaneously develop into gross fragments and the phase change is complete.

Types of ice nucleation

Nucleation is of two different types – homogeneous nucleation (that occurs in 100% pure water) and heterogeneous nucleation (that occurs in impure water). Heterogeneous ice nucleation is common in nature, where water aggregates in a crystalline arrangement and suspended foreign bodies, surface film or wall of the container serve as nucleating agent[6]. A decreased degree of super cooling is required for the heterogeneous ice nucleation. Many organic and inorganic substances like silver iodide[7], phloroglucinol dihydrate, alpha phenazine, metal aldehyde, kaolinite, covellite, magnetite[8], cholesterol[9], amino acids[10], lectins and proteins[11] are well known ice nucleators. However, biological ice nucleators are also well established. Among all these, INA bacteria are the most active.

Most of the INA bacteria are inhabitants of plant surfaces and some of them are also plant pathogens[12]. In general, they are gram-negative nonspore forming rod-shaped bacteria. Some of them are known to produce plant toxins (syringomycin from *P. syringae*) but are non-toxic to humans. These organisms have faster growth rate[13] and spread through aerosols[14].

Molecular biology of ice nucleation

INA protein, conferring ice-nucleating property to a bacterium is encoded by a single gene located on a small stretch of chromosomal DNA whose size ranges from 3.4 kb to 7.5 kb. The *Ina* genes that have been sequenced completely are from genus *Erwinia* (*InaA, InaU, IceE*), *Pseudomonas* (*InaZ, InaW*) and *Xanthomonas* (*InaX*). The *Ina* gene contains one open reading frame (ORF) of ~3600 bp, of which 80% consists of a series of imperfectly repeated DNA sequence with lengths of 24, 48, 144 bp. The DNA sequences of the ORF are highly homologous, whereas the sequences lying outside the ORF are usually non-homologous and

---

The authors are in the Molecular Biology Unit, Dairy Microbiology Division, National Dairy Research Institute, Karnal 132 001, India.

the translation product is comparatively more conserved than the DNA sequence[15]. INA proteins produced by different INA$^+$ bacteria, immunologically cross react with each other indicating their similar antigenic structure. The translation product of INA gene is predicted to contain 1200 amino acids and has a molecular weight of around 120 kDa, comprising of contiguous repeats of a consensus octapeptide (Ala–Gly–Tyr–Gly–Ser–Thr–Leu–Thr) (ref. 1).

INA protein consists of three distinguishable domain structures – a unique N-terminal domain (~15% of total sequence), which is relatively hydrophobic and contains the membrane anchor for ice nucleation protein; a unique C-terminal domain (~4%) which is rich in basic residues and very hydrophilic; and a central repeating domain (81%), which is hydrophilic and rich in alanine, glycine, tyrosine, threonine, serine and leucine. This central domain can be sub-divided into three regions. The first two of these repeats consist of 48 peptide units of high fidelity; each 48-peptide unit can be further divided into three 16-peptide repeat units of medium fidelity; again, each 16-peptide unit can be further divided into two 8-peptide repeat units of low fidelity in which only two of the eight peptides are strongly conserved. The third region of the repeating domain contains only an 8-peptide repeat sequence (Figure 1).

The repeating domain is naturally suited to formation of a repeating template structure. This domain is rich in amino acid residues with neutral hydrophilic side chains capable of forming hydrogen bonds with water molecules[2,16]. Removal of several 8-amino acid repeating blocks lowers the nucleation-threshold temperature but does not abolish the nucleation activity[17]. The symmetry of this sequence is similar to that of certain crystal planes of ice[2,18]. Highly active bacteria contain only a few thousand copies of protein in each cell[19–21]. The repeating domains of this INA surface protein are capable of organizing water into an ice-like structure in three dimensions. The secondary structure of the protein is thought to be a beta-pleated sheet, punctuated by 5 to 6 turns per 48 amino acid sequences[22].

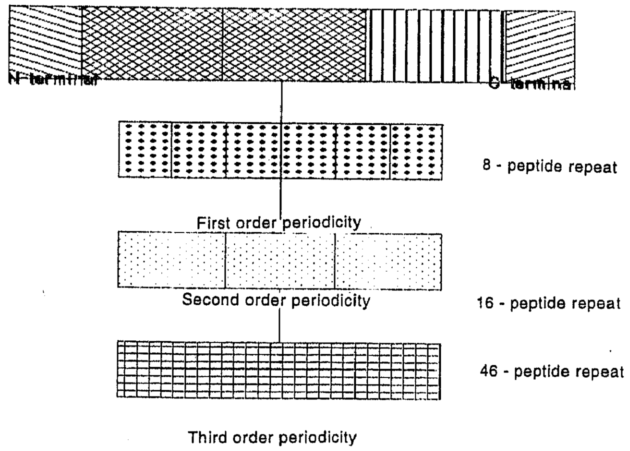

Figure 1. Diagrammatic representation of INA protein. (Adapted from ref. 52).

Factors affecting ice nucleation

Several chemical compounds known to disrupt membranes have been shown to decrease or abolish bacterial ice nucleation activity. Loss of membrane lipids causes loss of ice nucleation activity[23,24]. Treatment of bacterial cell wall with lipases, lipid extracting agents, quaternary ammonium compounds, detergents and dyes, etc., decreases the ice nucleation activity. The treatment of bacterial cell membrane with proteases and protein denaturants[25] affects functionality of INA protein. The change in temperature also causes disaggregation of INA protein[21], antibodies[26] and antifreeze glycopeptides[27], which physically blocks the water-binding surface of INA protein. Nucleation threshold temperature and nucleation frequency of INA$^+$ bacteria depend upon the dynamic assembly of multiple, membrane-bound aggregates of ice-nucleation protein. Though in most cases, INA protein is observed in cell membrane, *E. herbicola*, on the other hand, shed ice nuclei into medium. These are released as membrane vesicles of size 50–200 nm in diameter, which are active at –2 to –10°C and show similar freezing spectrum like that of intact nuclei[28]. These vesicles can also be stored at 0 to 4°C for weeks with no loss of activity. But, heating of these cell-free nuclei at 30°C causes rapid and irreversible loss of ice-nucleation activity.

Nucleation capability mainly depends upon the cell concentration. If the cell number/population is high, the temperature required for nucleation will also be higher. The dead cells also retain INA$^+$ activity, if there is no lysis. Approximately, 10^6 cells are required at –2°C to initiate nucleation, but at very high cell concentration (> 10^7 cells/ml), nucleation activity is independent of cell number/population. The other factors that contributed to the nucleation efficiency of INA protein are its lattice match and symmetry, water solubility, size of nucleation site, polarization ability, hydrophobicity, surface charge, number and strength of surface sites capable of absorbing water molecules[29].

Assay for ice nucleation activity

The best and rapid method for measurement of bacterial ice nucleation activity is droplet freezing assay. In this process, INA$^+$ bacteria are diluted and about 10 µl sample mix is placed on hydrophobic surface which remains floating on the surface of a refrigerated bath. The temperature is lowered step by step and at each point, the number of droplets frozen is counted to estimate the nucleation efficiency[30,31]. The common factors which probably affect bacterial ice nucleation assay are temperature, pH and volume of the drop, heat transfer capacity of cooling surface, concentration of cells, the ratio of ice nuclei per cell, time period and the temperature at which droplets are held.

Contrary to INA proteins, antifreeze glycopeptides seen in some fish, spiders, mites, plants, fungi (*Pleurotus ostreatus, Flamulina velupites*), bacteria (*Micrococcus cryophilus, Rhodococcus erythropolis, P. putida*)[32] interact directly with ice crystals and stop the increase in size of ice crystals. As it binds to surface of ice crystal embryo, it physically blocks part of the water-binding surface of INA protein. This results in neutralization of the action of INA protein and hence causes freezing point depression by adsorption inhibition[27]. At times, the presence of antifreeze proteins in food causes problems in freeze texturization[33].

With the advancements of recombinant DNA technology, the *InaA* gene from *E. herbicola* has been successfully cloned and expressed in *E. coli*[34]. Not only *InaA*, some other genes like *InaZ* of *P. syringae*, etc. associated with ice nucleation have also been cloned successfully in *E. coli*[20] and other hosts, thereby, leaving ample scope to explore their commercial value and applications in myriads of areas.

Applications of bacterial ice nucleation

Artificial snow making

Snow is a loose ice mass entrapping air inside, which is highly resistant to temperature. In general, snow is manufactured by spray freezing operation using a snowgun, which handles between 10 and 100 gallons of water per minute along with several hundred cubic feet of compressed air and the process is very energy intensive. Snow is commonly used for recreational skiing, skating and ice hockey grounds. Recently, Eastman Kodak in collaboration with Advanced Genetic Sciences, Inc. (now a part of DNA Plant Technology Corp.) has patented a product called SNOMAX which is nothing but a freeze dried, radiation sterilized powder of bacteria *P. syringae* PS 31. Each gram of freeze dried powder contains about 10^{11} ice nuclei with nucleation threshold of –5°C or warmer. The main advantages imparted by Snomax include reduction in energy consumed by snowmaking machines for each unit of snow produced and an improvement in the recreational quality of artificial snow[35]. This product has not yet been marketed in India and as it is prepared by following common fermentation technology, its cost will come around the same as already exists for freeze dried preparations of *Bacillus thuringiensis* used all over the world as a bioinsecticide. Use of this product reduces the time and temperature required, therefore, considerably improving the economics of snow making.

Freeze-texturing using INA$^+$ bacteria

INA$^+$ *E. ananas* cells can be used for freeze texturing of foods. Addition of INA$^+$ bacterial cells to isotropic aqueous dispersion of hydrogels composed of proteins and polysaccharides converts bulk of water into directional ice crystals at subzero temperature, not lower than –5°C and forms an anisotropically textured product. Slicing rightangle to the lamellae of flakes formed produces fibrous textured food. INA$^+$ bacteria inhibit supercooling of the bulk water in aqueous dispersions and hydrogels of food proteins and polysaccharides. This effect changes the ice crystallization process which improves the texture of food. This method is commonly applied to heat-sensitive foods which need texturing. INA$^+$ bacterial texturization has been successfully experimented in raw egg white, bovine blood, soybean curd, milk curd, corn starch paste, agar hydrogel, soybean protein slurries, hydrogels of glucomannan and calcium bridge glucomannan gel, etc[36]. Some of the advantages imparted by INA$^+$ bacterial texturization of food include preserving foods with high quality, saving the refrigeration cost, shortening the freezing time, improvement in quality of food especially flavour and taste, reduction in degree of super cooling, reduced initial freezing temperature, improved efficiency of production, increased freezing rate, formation of less damaging ice crystals and above all, saving of energy.

High pressure sterilized cells of INA$^+$ *X. campestris* INXC-1 have been permitted for food use in Japan. A Japanese company QPCo, Tokyo has already started commercial production of *X. campestris*. The food grade INA$^+$ bacteria must be environmentally safe, non-toxic, non-pathogenic and palatable to human beings. Generally, the use of live INA$^+$ cells in food systems is discouraged and hence, these should be killed before use by high pressure treatment or radiation[37]. But, this has a promising future as the ice nucleation gene can be cloned to edible food grade organisms like *Lactobacillus* or yeast which can be consumed directly.

Freezing foods using INA$^+$ bacteria

INA$^+$ bacteria have successfully been used for freezing of salmon fish muscle, whole fish, surmi, ice cream, agar gel, sucrose solution, fruit juices, egg white, coconut oil, sunflower oil, milk and dairy products. The application of INA$^+$ bacteria in freezing provides quick freezing, increase in nucleation temperature and energy saving. It has been reported that the INA$^+$ *P. syringae* cells can cause a whole fish to freeze consistently at –5°C within few hours, whereas up to 33% of the untreated fish do not freeze at the same temperature[38]. The total energy saving is due to the savings made during the freezing process as a result of the total freezing time being shortened and the saving made during the storage of frozen foods. For example, a frozen food plant may be able to operate at –30°C rather than at –40°C, because the use of INA$^+$ bacteria will ensure that the foods freeze at a relatively higher temperature[24]. If this plant operates at 5000 kV, the difference of electrical load between these two temperatures will be around 313 kW. Hence, the use of INA$^+$ bacteria will save a lot of energy.

Freeze drying using INA$^+$ bacteria

The cells of *E. ananas* were applied for the freeze drying of food items such as soy sauce and soybean paste, which are difficult to freeze under normal conditions. Such high salt containing food items are usually diluted for effective freezing[39]. The addition of INA$^+$ cells has made it possible to shorten the freezing times of these foods and to obtain powdered freeze-dried product with greater efficiency.

Freeze concentration using INA$^+$ cells

The cells of *E. ananas* entrapped in calcium alginate are also used for freeze concentration purpose. Generally, INA gel is placed in a desired position in liquid to be concentrated and gradually the temperature is lowered. Ice crystals formed at INA gel site along with INA gel are removed to get a concentrated product[40]. *E. ananas* IN-10 and *X. campestris* INXC-1 can be used for freeze concentration. Fresh milk, lemon juices, strawberry paste, raw egg white have been successfully concentrated using this technique[40].

BIND assay

Bacterial ice nucleation diagnostic (BIND) assay was developed by DNA Plant Technology Corporation, USA for detection of *Salmonella* in food[41]. This method uses the recognition specificity of a bacteriophage P22 and the sensitivity of the gene (*InaZ*) encoding ice nucleation protein for detection of pathogens in foods. To explain it at molecular level, *Ina* gene introduced to a bacteriophage is kept under the control of a strong promoter by recombinant DNA technology, the phage is allowed to transduce the target bacteria and the test sample is cooled to –9.5°C in presence of a freezing dye which shows fluorescent green colour at super-cooling. This indicates absence of target organisms and shows non-fluorescent orange colour at freezing, indicating the presence of target organisms, i.e. *Salmonella*. The frequency of freezing of test samples can indicate the degree of contamination. This method has been employed successfully in raw egg, milk, meat, gelatin, etc. to detect *S. typhimurium*, *S. dublin*, *S. paratyphi B*, *S. enteritidis*, *S. gallinarum* and *S. typhi*. The method is quick and shows high specificity and sensitivity and can detect even < 10 cells/ml of sample[42]. In BIND assay, non-target organisms do not interfere and it can also detect injured cells as only 100–200 INA protein molecules are required for detection. But, it has certain disadvantages, i.e. it cannot detect phage-resistant cells and also fails to detect dead cells. Moreover, as this method fully depends upon specificity of phages, it cannot be employed for detection of certain bacteria for which bacteriophage is not known.

Control of frost damage to plants

As most of the INA$^+$ bacteria are the common inhabitants of phylosphere, they cause great damage to crop plants like wheat, oat, barley, mustard, etc. by inducing ice formation on plant surfaces[43]. The economic impact of frost damage in US has been estimated to be over a billion dollars per year[44]. Several methods are now in vogue to control frost damage to plants like genetic improvement, use of protective covers, use of wind machines and heaters, application of water to plants, application of chemicals, use of antifreeze proteins, etc. of which ice-minus bacteria are gaining importance day by day.

Ice-minus bacteria are nothing but the INA$^+$ bacteria engineered genetically (*Ina* gene removed) to lose its ice-nucleating power[45,46]. Generally, ice-minus bacteria are sprayed on plant surfaces before ice-plus population develop and grow to a sufficient number to prevent the latter from colonizing. This method has given excellent results as 70–80% reduction of ice accumulation has been observed on strawberry plant[47]. But, till date Environmental Protection Agency and government have not permitted release of these organisms to nature. However, these ice-minus bacteria do not express any competitive advantage over the wild strains of ice-positive bacteria, therefore, it is difficult to control INA$^+$ population on plant surfaces in uncontrolled natural environment.

Other possible uses

Bacterial ice nucleation finds possible applications in replacement of silver iodide in artificial rain (cloud seeding and cloud precipitation); in air-conditioning for improvement of its efficiency; in refrigeration system and ice-flacking machine; processing of antifreeze protein containing foods; identification of pathogens and reduction of cold tolerance of insects in frozen grain storage[48,49]. Certain US patents concerning the use of INA protein and its related products for fluorescent immuno assay kit, treatment of hazardous waste, purification of organic chemicals have also been developed. Use of BIND assay can be extended to study the sensitivity of the bacteria to bacteriocidal agents. The initial discovery that plant surfaces shed bacterial ice nuclei in the environment was prompted by the general interest by meteorologists in ice nucleation[50]. Since then, a lot of intensive investigations have been continuing by different groups on the incidence and importance of bacterial ice nucleation in the atmosphere[51]. But till today, the meteorological significance of bacterial ice nuclei remains unproven.

Conclusion

Ice nucleating bacteria can play a significant role not only in affecting our environment but also influencing our day to day life. Although most of the possible applications involving these ice nucleation proteins are at their embryonic stages at the moment, their application and scope are bound to increase in the near future as more basic information on these wonder proteins pour in.

Aerosol measurements at Trombay relating to the 1995 solar eclipse

B. K. Sapra, Y. S. Mayya, V. D. Sawant and K. S. V. Nambi

Environmental Assessment Division, Bhabha Atomic Research Centre, Mumbai 400 085, India

This study examines the effect of the solar eclipse on the characteristics of atmospheric environment, particularly on the aerosol concentrations at Trombay, Mumbai. Results of the measurements indicated 2–4 fold increases in the aerosol number and mass concentrations which occurred mainly in the sub-micron size range and were not noticeable above 1.0 µm. The increases occurred after a time lag of about 80 min from the beginning of the eclipse. These may be explained in terms of the combined effect of condensational growth due to increased relative humidity and a build-up of particle concentrations arising out of a suppressed level of atmospheric turbulence.

A total solar eclipse occurred on 24 October 1995. A study was undertaken to examine its effect, if any, on the characteristics of the atmospheric aerosols. The eclipse was total in Rajasthan, Uttar Pradesh and West Bengal and partial in Mumbai (72% obscurity) lasting from 0725 h (IST) to 0945 h with a peak at 0831 h. A total eclipse was last seen in India across the southern Indian peninsula on 16 February 1980. A large body of information exists on several atmospheric effects of the eclipse such as the solar radiation measurements[1–4], ozone levels[5], radon levels[6], atmospheric conductivities[7], etc. However, there exists no report of measurements on the eclipse-related behaviour of aerosols, although it is expected that cooling of the atmosphere due to reduced solar radiation intensity would result in increased aerosol levels. The need for these measurements arises from the fact that they are useful in interpreting the changes in the ground level radiation fluxes and atmospheric conductivities occurring during the eclipse. This also gives an idea of the response time of the atmospheric particles to the solar radiation changes. Besides, ambient aerosols can affect public health; from this point of view also, it is important to ascertain the change in aerosol levels, if any, during the solar eclipse.

Methodology

Several supporting measurements, viz. solar radiation variations, meteorological parameters and major pollutant levels were made, the details of which are published elsewhere[8]. However, here we emphasize the aerosol measurements as they have shown interesting changes. These were made at a height of about 10 m above the ground at the terrace of Modular Laboratory building inside Bhabha Atomic Research Centre on the day of the eclipse (24 Oct.) as well as on the preceding (23 Oct.) and succeeding days (25 Oct.) between 0700 and 1300 h. A brief description of the different monitoring instruments used and the observations made is as follows.

Mass-size distribution

The mass-size distribution measurements of the aerosols were carried out using the Quartz Crystal Microbalance Cascade Impactor (QCMCI), which is a near real-time measuring instrument operating at a flow rate of 0.24 lpm. It measures the suspended particulate matter (SPM) concentration (µg/m^3) and the mass distribution in ten size intervals with lower cut-off sizes at 0.05, 0.1, 0.2, 0.4, 0.8, 1.6, 3.2, 6.4, 12.5 and 25 µm. Size classification is achieved by impaction on quartz crystal substrates and estimating the deposited masses on each stage by relating them to the changes in the oscillation frequencies of the crystals. The measurements were made every ten minutes.

Number-size distribution

The number size distribution measurements of the aerosols were carried out using three different instruments at every ten-minute interval. Two of them were optical particle counters (OPCs of Met-One and Malvern), while the third was the automatic condensation nucleus counter (ACNC) developed indigenously[9].

The Met-One OPC is a single particle counter based on the principle of scattering of a laser beam by particles and operating at a sampling flow rate of 2.8 lpm. It monitors the number concentration (no./cc) in six size ranges with the lower cut-off sizes at 0.1, 0.2, 0.3, 1.0, 3.0 and 5.0 µm. The size classification is achieved by relating the scattered intensity from each particle to its size. The other OPC (Malvern) is a portable instrument which monitors the number concentration in 4 size intervals with lower size cut-offs at above 0.3, 1.0, 3.0 and 5.0 µm. It essentially works on the same principle and flow rate as the Met-One OPC, but uses a laser diode as the light source.

The total particle number concentrations in the entire size range (> 0.003 μm) were monitored using the ACNC. It works on the principle of condensing water vapour on otherwise undetectably small particles and allowing them to grow in sizes at which they are detected through scattering of light.

Results

Figure 1 *a* shows the variation of the SPM concentration with time beginning at 0700 h up to 1330 h (330 min) for the three days as per the protocol. On the days preceding and succeeding the eclipse day, the variations are similar and indicate a level ranging from 10 to 80 μg/m^3. A general trend of decrease interspersed with minor peaks and troughs is seen as the day progresses. However, on the eclipse day, the behaviour is distinctly different and several phases of change are noticed. The mass levels were significantly high in the early morning (0700 h) which can be attributed to the haze that was observed that morning and then decreased rapidly to a low value at the time of the onset of the eclipse. The most noticeable aspect is the sharp increase to a value of 140 μg/m^3 beginning at 0850 h and lasting up to 1020 h. The duration of this peak (≈ 90 min) is comparable to that of the eclipse (80 min), although it manifests after a time lag of about 85 min with respect to the beginning of the eclipse. This lag is to be qualitatively expected since the aerosol behaviour is coupled to several complex atmospheric processes related to the reduction in the solar intensity and consequent cooling. After this period, the levels remained higher than those found on the other two days. A size-resolved analysis of the data (Figure 1 *b,f*) indicates that a significant part of the increases observed during the eclipse period is attributable to the particles in the 0.1–0.4 μm MMAD range. For larger sizes, this increase progressively diminishes.

Similar results are obtained for the number size distribution of aerosols. The measurements by Met-One OPC in the size group above 0.3 μm, presented in Figure

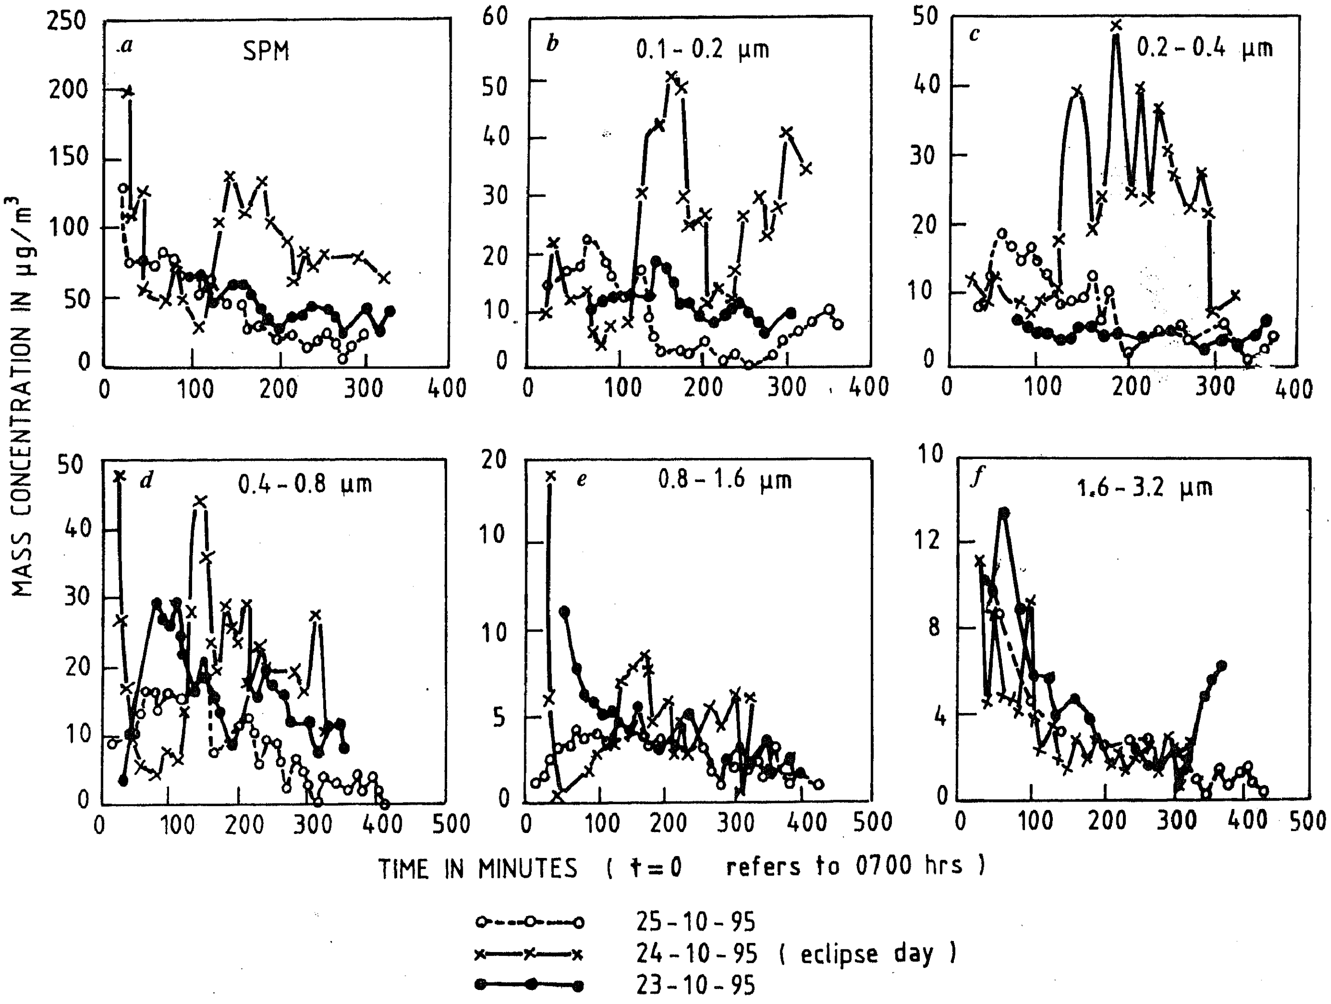

Figure 1. Temporal variation of mass concentration in different size groups as monitored by quartz crystal microbalance cascade impactor.

2 *a*, indicate that the concentration levels are low on the days preceding and succeeding the eclipse and there is a sharp peak corresponding to the eclipse period. The crest-to-trough ratio is about 3.5, similar to that observed for mass concentrations. The elevated concentrations during the haze period as well as in the post-ecliptic period are also reproduced here. Like in the case of QCM measurements, the size-resolved analysis (Figures 2 *b*, *e*) indicates a significant contribution to this increase from the size range of 0.3–0.5 μm. The results with the Malvern OPC in the size range > 0.3 μm, especially the peak number concentration observed during the eclipse period are also in conformity with those of the Met-One OPC.

The variation of the total number concentration of particles (> 0.003 μm) as measured by ACNC is shown in Figure 3. The overall trend including the concentration increase is similar to that observed with the other instruments, the main contribution in this case being from the ultrafine nuclei (< 0.1 μm) which are not recorded with the OPCs. The main difference is the appearance of a wider peak (≈ 160 min) with a greater lag time than that shown by the other instruments.

Discussion

The results indicate that an increase in the aerosol concentration (mass as well as number) did indeed occur between 0830 and 1030 h on the eclipse day which can be directly attributable to this phenomenon. The explanation, in all likelihood is contained in the time variation of the relative humidity (RH) and atmospheric turbulence profiles for that day. The temperature and humidity profiles for the eclipse day and the next day are shown in Figures 4 *a* and 4 *b* respectively. On the eclipse day, there is a definite cooling by about 2°C in the period between 0800 and 0900 h. Coincidentally, the RH was high (~90%) in the early morning hours of the eclipse day and is linked to the prevalence of the hazy conditions (which was not the case the next day). It decreased rapidly to 69% by 0800 h. Between 0800 and 0900 h, it showed an increase to a level of about 80%, consistent with the decrease in temperature. This can lead to condensation effects, especially on salt particles expected to be present in Trombay (situated on the sea coast), which manifest as increases in the number concentrations as well as in the mass concentrations. The former increase is due to the shift of very fine undetectable particles into the detection range of the OPCs and the latter includes the actual change in the mass of the particles due to water vapour condensation. It may be noted that the observed increases in concentrations (Figures 1–3) occurred after about 0840 h, but lasted much longer than the duration of humidity changes.

The observed changes will also be related to wind and turbulence conditions in the atmosphere. The wind

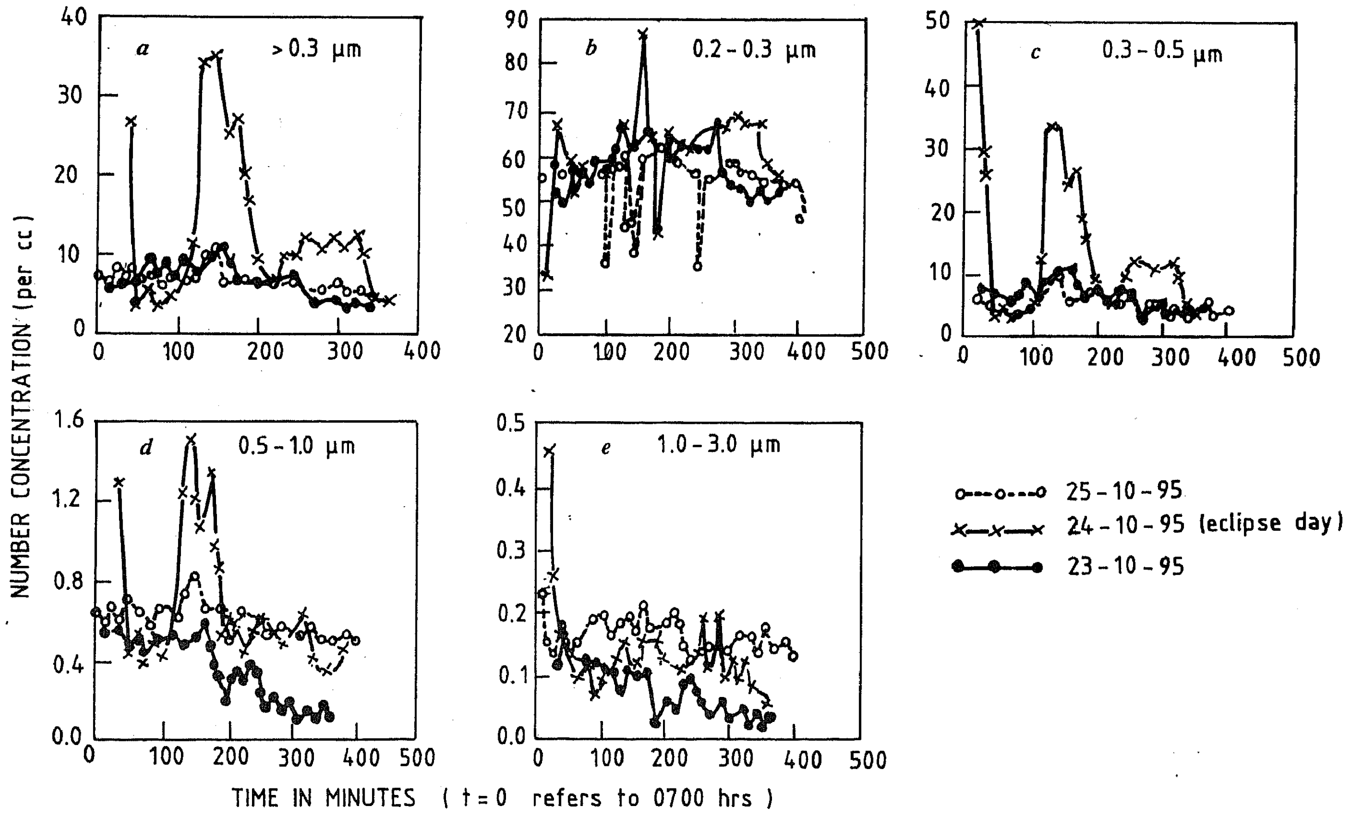

Figure 2. Temporal variation of particle number concentration in different size groups as monitored by optical particle counter.

speed, direction and standard deviation in the direction (σ_θ) are presented in Table 1 for the three days. As may be seen, both the wind speed and σ_θ were lowered during the eclipse period and calm conditions prevailed. Aerosol build-up under such conditions is a likely cause of the observed increases.

Another supportive argument for the prevalence of calm conditions and lower turbulence levels during eclipse is provided by the atmospheric back-scatter profiles up to a height of about 1000 m recorded by the SODAR (Sound Detection and Ranging) system installed at BARC. These are directly related to the thermal turbulence present in the atmosphere. The SODAR echograms for the time–height profiles showed lower back-scattered intensities (lower turbulence levels) at the ground level (below 200 m) during the eclipse period, in contrast to that on the next day during the same period. This would lead to an overall build-up of particle concentrations. The increase monitored by the ACNC (a significant part of which falls in the Aitken size range) which cannot be directly explained in terms of the humidity effects, is largely attributed to this build-up effect. A possible increase in the ground level radon concentrations as was observed during the earlier solar eclipse[6] can lead to the production of small ions. These can result in the enhancement of the concentration of radon-generated-ion-induced nuclei in the presence of water vapour that might be an additional reason for the increases observed with the ACNC.

1100	7	ENE	–	6	ESE	8.3	8	ESE	10.5
1200	8	NE	–	5	SE	9	6	ESE	13.5

V: Variable; C: Calm; σ_θ: Standard deviation in the wind direction (in degrees).

As may be seen, there was a second increase in the mass and number concentrations at about 300 min (1100 h) on the eclipse day. At the same time, we note that the temperature showed a decrease (from 36°C to about 33°C) with a corresponding rise in humidity from 50% to 80%. This suggests a possibility of repeated condensational growth due to natural changes in meteorological conditions.

An important point to be noted while comparing the size-wise results of the OPCs with those of the QCM is the differences in the interpretation of the sizes. The OPCs refer to the light-scattering diameter which for spherical particles would be the geometrical diameter. The QCM, on the other hand, groups particles according to their aerodynamic diameters, which depend on the aerosol density. As the density is not clearly known in the present case (although a value of 1.5–1.8 g/cc might be appropriate for aerosol particles), size comparisons are made only to indicate the trends. Another point is that the changes in the number concentration implies generation or build-up of particles but does not give information on their growth due to condensation. On the other hand, changes in the mass concentrations include this aspect as well.

Conclusions

There does not exist previous data on aerosol build-up from direct measurements during solar eclipse. Nevertheless, this had been earlier inferred from the lowered atmospheric conductivity measurements[7]. The present studies provide a direct confirmation of the expected increases in the aerosol concentrations due to the build-up effect. Although the changes in the temperature and relative humidity are small during the eclipse, they seem to have an important bearing on the observed increases in the aerosol concentrations. Apart from this, suppression of ground level turbulence and also possible enhanced nucleation processes induced by radon-generated ions, could be other explanations for the observed increases.

Role of thyroidal and testicular hormones in regulation of tissue respiration in hibernating and non-hibernating species of frogs

B. B. P. Gupta and A. Mahanta

Department of Zoology, North-Eastern Hill University, Shillong 793 022, India

***In vivo* and *in vitro* effects of L-triiodothyronine (L–T_3), L-tetraiodothyronine (L–T_4), propyl thiouracil (PTU), testosterone (T) and cyproterone acetate (CA) were studied on the rate of tissue respiration in Indian streaked frog, *Rana limnocharis* (a hibernating species) and Indian skipper frog *Rana cyanophlyctis* (a non-hibernating species) maintained under natural climatic conditions during winter and summer months. The rate of tissue respiration was measured with the help of an oxygen electrode. Hormones were used in physiological doses. PTU invariably decreased respiratory rate in both the species. However, tissues of *R. cyanophlyctis* were comparatively more sensitive to thyroid hormones. Both *in vivo* and *in vitro* administration of testosterone significantly increased and *in vivo* administration of CA significantly decreased the rate of tissue respiration in both the species irrespective of seasons and temperature. These findings suggest that while the oxidative mechanisms of the two species differ in their sensitivity to thyroid hormones, endogenous thyroid hormones seem to play an important role in energy metabolism of frogs. Further, testicular hormones seem to be directly involved in the regulation of the oxidative metabolism and might be responsible for maintaining normal activity of *R. cyanophlyctis* during winter months.**

HORMONES play a major role in the regulation of the oxidative metabolism in vertebrates and ensure energy production for normal functioning of a large number of organs. Investigations over the last four decades have revealed that the energy metabolism in homeotherms is controlled primarily by thyroid hormones[1–3]. However, these hormones stimulate the metabolic rate of poikilotherms only at ecritic/high temperature (25°C or above)[4,5]. There are only a few reports regarding the role of thyroid hormones in the regulation of metabolic rate of amphibians in relation to ambient temperature[6,7]. Moreover, these studies were conducted at simulated temperatures on temperate zone amphibians maintained under laboratory conditions[8–12], and so far no attempt has been made to investigate the role of thyroid hormones in the calorigenesis of amphibians maintained under natural climatic conditions[5]. Recent studies suggest that gonadal hormones might be actively involved in the regulation of respiration in reptiles exposed to low temperatures where thyroid hormones generally do not influence the oxidative metabolism[5,13]. Notwithstanding these reports, however, there is scarcity of information on the role of gonadal hormones in the amphibian oxidative metabolism, particularly at low temperature[14,15]. Further, there are anurans which do not experience cold torpor (hibernation) even during severe cold winter months. But so far no attempt has been made to study the differences between hormonal regulation of the oxidative metabolism in hibernating and non-hibernating species of frogs with special reference to natural ambient temperature and gonadal activity[5]. Therefore, keeping in view the critical phylogenetic position of amphibians and lack of information, it was thought worthwhile to undertake a study of the role of thyroidal and gonadal hormones in the regulation of the oxidative metabolism of a hibernating and a non-hibernating species of frogs maintained under natural climatic conditions during winter and summer months.

Materials and methods

All experiments were conducted on male Indian streaked frog, *Rana limnocharis* (a hibernating species; body weight: 8–10 g; snout to vent length: 31–33 cm) and Indian skipper frog, *Rana cyanophlyctis* (a non-hibernating species; body weight: 10–12 g; snout to vent length: 35–39 mm) which are found in and around Shillong (Lat., 25°30′N; Long., 91°52′E; altitude: 1450 m ASL; minimum temperature: 0–4°C, maximum temperature: 26°C). *R. limnocharis* develops anorexia and becomes lethargic during winter months (November to January) and breeds during rainy/summer season (April to August). *R. cyanophlyctis* does not exhibit cold torpor/hibernation and remains physically and reproductively active throughout the year[16,17].

Chemicals

All the hormones and the chemicals were purchased from Sigma Chemicals, USA.

In vitro experiments

Male *R. limnocharis* and *R. cyanophlyctis* were collected from nature during December (winter, temperature: 6–14°C) and July (summer/rainy season: temperature: 14–21°C). Four frogs of each species were killed immediately after collection, and tissues (liver and skeletal muscle) were rapidly removed, rinsed in ice-cold frog Ringer's solution and stored in a freezer (– 10°C to – 15°C) for *in vitro* hormonal treatments. Storage in freezer for up to 15 days has no effect on the rate of tissue respiration. The stored tissues were used within 10 days from the date of collection for *in vitro* treatments. For treating the tissues with hormones, tissues were blotted, weighed and homogenized in ice-cold frog Ringer-phosphate buffer solution (pH 7.4) using a loose-fitting glass homogenizer. One ml of tissue homogenate (16–20 mg tissue/ml), 3.9 ml of Ringer-phosphate buffer and 0.1 ml of hormone solution (having desired concentration of hormones) were used for measuring the rate of tissue respiration. The homogenates treated with L-triiodothyronine (L–T_3) (0.6 µM), L-tetraiodothyronine (L–T_4) (0.5 µM) and testosterone (1.38 µM) were preincubated at 4°C prior to the measurement of the rate of tissue respiration using an oxygen electrode.

In vivo experiments

Male *R. limnocharis* and *R. cyanophlyctis* were collected from the field during December (temperature: 7–15°C) and July (temperature: 12–21°C) and maintained in plastic cages with mud and water. The cages were fully exposed to the natural climatic conditions. The frogs were acclimatized for 10 days. After acclimatization, the frogs of both species were separately divided into 6 groups of 4 each during winter. The first group of each species was injected only frog saline (0.1 ml) and served as control. Groups 2, 3, 4, 5 and 6 were administered L–T_4 (2 µg/frog), L–T_3 (2 µg/frog), propyl thiouracil (PTU) (1 µg/g body weight), testosterone (2 µg/frog) and cyproterone acetate (CA) (1 µg/g body weight) respectively. All the injections were given intra-muscularly at an interval of 24 h between 9 am and 10 am for four days. The frogs were provided with live earthworms as food *ad libitum*. Twentyfour hours after the last injections, frogs of each group were decapitated, tissues (liver, skeletal muscle and kidney) were rapidly removed, rinsed in ice-cold frog Ringer's solution, and stored in a freezer (– 8°C) for measuring the rate of tissue respiration with the help of an oxygen electrode. During July, after acclimatization, frogs of each species were divided into ten groups of four each. Group 1 of both the species received only saline (0.1 ml) and served as control. Groups 2, 3, 4, 5 and 6 were administered L–T_3, L–T_4, PTU, testosterone and CA respectively. The doses, mode of administration and the duration of administration of the hormones were the same as those during the winter months. Frogs of groups 7, 8, 9 and 10 were intra-muscularly injected epinephrine (2 µg/frog), norepinephrine (2 µg/frog), PTU + epinephrine (1 µg/g + 2 µg/frog) and PTU + norepinephrine (1 µg/g + 2 µg/frog) respectively at an interval of 24 h between 9 am and 10 am for four days. Twentyfour hours after the last injections, frogs were decapitated and tissues were procured, processed and stored for the measurement of respiratory rate following the procedure mentioned earlier. The stored tissues were processed within 10 days for the measurement of the rate of tissue respiration.

Measurement of the rate of tissue respiration

The rate of tissue oxygen consumption was measured with the help of an oxygen electrode (Digital Oxygen System Model 10, Rank Brothers Ltd, UK). For measuring tissue respiration, tissues were blotted, weighed and homogenized in ice-cold frog Ringer-phosphate buffer solution (pH 7.4) using a loose-fitting glass homogenizer. The polarizing voltage was kept at 0.6 V and the homogenizing medium was used as the polarizing medium. Since the preferred body temperature of most amphibians ranges between 25 and 28°C (ref. 18), temperature of the incubation chamber of the electrode was maintained at 25°C with the help of a thermostat-controlled water circulator. The homogenates were incubated in the incubation chamber of the oxygen electrode for 20 min before recording the readings. Readings for each tissue were taken for 30 min in the linear range of oxygen consumption. The rate of tissue respiration was calculated and expressed as µl O_2/mg wet tissue/hour (ref. 15). The data were tabulated and analysed using Student's *t* test[19]. A probability of less than 5% was considered to be significant.

Results

In vitro experiments

The data are presented in Table 1. *In vitro* treatments with L–T_3 and L–T_4 did not stimulate liver and muscle tissues respiration of both the species during winter and summer (Table 1). However, the respiratory rate of the tissues was significantly increased following *in vitro* treatment with testosterone during both winter and summer (Table 1).

In vivo experiments

The data are presented in Table 2. *In vivo* administration

^{d,e,f}Differ from respective EP or NE treated group: $P < 0.05$, $P < 0.01$ and $P < 0.001$, respectively.
CA = cyproterone acetate; EP = epinephrine; NE = norepinephrine; PTU = propyl thiouracil; L–T$_3$ = L-triiodothyronine; L–T$_4$ = L-tetraiodothyronine, T = testosterone.

of L–T_3 and L–T_4 had no significant effect on the respiratory rate of tissues in *R. limnocharis* during winter and summer (Table 2). However, L–T_3 administration in *R. cyanophlyctis* significantly stimulated the respiratory rate of muscle and kidney during winter and only of kidney during summer. Unlike L–T_3, *in vivo* treatment with L–T_4 had no effect on the respiratory rate of tissues of *R. cyanophlyctis* during winter and summer except kidney respiration which was stimulated during the summer (Table 2). Administration of PTU invariably and significantly decreased the respiratory rate of all tissues in both the species during summer as well as during winter seasons (Table 2).

In vivo administration of testosterone significantly stimulated and CA significantly decreased the respiratory rate of all the tissues (except of muscle in *R. limnocharis* during summer) in both the species during both summer and winter seasons. CA-induced decrease in the respiratory rate of muscle in *R. limnocharis* during summer was found to be marginally insignificant (Table 2).

In vivo administration of epinephrine (EP) and norepinephrine (NE) significantly stimulated the respiratory rate of tissues in both the species during summer (Table 2). However, when EP and NE were administered in combination with PTU during summer, the stimulatory effect of the catecholamines on tissue respiration was significantly reduced compared to the respective groups which received only catecholamines (Table 2).

Discussion

The thyroid hormones did not stimulate the respiratory rate of tissues of *R. limnocharis* which undergoes hibernation/cold torpor during winter months irrespective of seasons, temperature and mode of treatment. However, *in vivo* administrations of L–T_3 and L–T_4 were found to stimulate the respiratory rate of muscle and kidney of *R. cyanophlyctis* (which remains active throughout the year) during winter and summer respectively (Table 2). It seems that tissues of the two species differ in their response to calorigenic action of thyroid hormones. Further, *in vivo* administration of PTU (a goiterogen which blocks synthesis of thyroid hormones) significantly decreased tissue respiration in both the species during both winter and summer months (Table 2). Thus, there is a possibility that the endogenous levels of T_3 and T_4 are actively involved in the regulation of the oxidative metabolism in both the amphibian species during both summer and winter months. There are reports that exogenous thyroid hormones significantly influence intermediary metabolism of poikilotherms exposed to low temperature[20,21]. In mammals exposed to low temperature, catecholamines regulate energy metabolism, and thyroid hormones reportedly support the non-shivering thermogenesis by potentiating the calorigenic action of catecholamine hormones[22–24]. Therefore, there is a possibility that endogenous thyroid hormones might be involved in maintaining the metabolic rate indirectly by potentiating the calorigenic action of catecholamines. This assumption is strongly supported by significant reduction in the stimulatory effect of EP and NE on tissue respiration when the catecholamines are administered with PTU compared to effects of catecholamines alone during summer (Table 2). The observed significant reduction in the calorigenic action of catecholamines in the presence of PTU might be due to decreased production of thyroid hormones and/or due to inhibition of deiodination of T_4 to T_3 (ref. 3). Potentiation of the calorigenic action of catecholamines in frogs by thyroid hormones seems to be of evolutionary significance. In reptiles also, thyroid hormones reportedly potentiate the metabolic effects of catecholamines at low temperature[25,26]. On the basis of these findings it can be suggested that for evaluating the calorigenic role of thyroid hormones in any amphibians/poikilotherms, use of goiterogens should be preferred over the use of exogenous thyroid hormones. In *R. cyanophlyctis*, comparatively higher tissue sensitivity to thyroid hormones might be associated with higher levels of physical and/or physiological/metabolic activity[5]. Thyroid hormones are reported to stimulate activities of several oxidative enzymes in fish and reptiles exposed to preferred body temperature[27–30].

Gonadal hormones have been reported to be directly involved in the regulation of the oxidative metabolism in several species of reptiles[2,5,13,31,32] and birds[33–35]. In the present study the rate of tissue respiration was invariably and significantly stimulated by testosterone in both the species in all the experiments. Further, in both the species *in vivo* administration of CA (a blocker of androgen receptors) significantly decreased the respiratory rate of tissues irrespective of seasons and ambient temperature. It, thus, seems that the observed decrease in tissue respiration following CA administration might be due to inability of endogenous androgens to bind to their specific receptors already occupied by CA. *In vitro* calorigenic action of testosterone strongly suggests that, as in reptiles[5,13], androgens are also directly involved in the regulation of the oxidative metabolism of amphibians. It is important to mention that during winter while spermatogenesis is arrested in *R. limnocharis*, in *R. cyanophlyctis* spermatogenesis has been reported to occur throughout the year with slight depression during winter months[16,17]. Thus, there is a probability that a comparatively higher level of androgens (as indicated by spermatogenesis) might be responsible for maintaining higher levels of metabolic rate of tissues and physiological activity in *R. cyanophlyctis* as compared to *R. limnocharis*. Direct involvement of testicular hormones in the oxidative metabolism of amphibians (present study), reptiles[5] and birds[1,33-35] suggests that androgens might be playing a dominant role in regulation of the metabolic rate in sub-mammalian vertebrates.

Biological control of sheath blight of rice: Induction of systemic resistance in rice by plant-associated *Pseudomonas* spp.

K. Krishnamurthy and S. S. Gnanamanickam

Centre for Advanced Studies in Botany, University of Madras, Guindy Campus, Chennai 600 025, India

In previous studies on the biological suppression of fungal diseases of rice with plant-associated rhizosphere bacteria we had reported that production of antifungal antibiotic (afa) by the bacterium is the major mechanism involved. In this study we report that the induction of systemic resistance in rice by strains of pseudomonads leads to suppression of sheath blight. A molecular tracking system (*lacZY* gene) was used to engineer strains of *Pseudomonas fluorescens* 7-14 and *P. putida* V14i. We used the *lacZ* expression as tracking system to monitor the survival and migration of the biocontrol agents. In spite of the absence of bacteria on plant surfaces, the endophytic bacteria present in the stem led to suppression of rice sheath blight caused by *Rhizoctonia solani* up to 18%.

THE application of beneficial pseudomonads as agents for biological control of plant diseases in agriculture is emerging as a potential alternative to the use of chemical fungicides. Evidence for mechanisms of biological control of pathogens cannot be exemplified by a single factor. The known mechanisms include, competition, production of antibiotics, siderophores, hydrogen cyanide, phytohormones, enhancement of nutrient uptake by the plant, extracellular enzymes, nitrogen fixation, enzyme synthesis to regulate the level of plant ethylene, and other substances[1–8].

Recent investigations on mechanisms of biological control by plant growth-promoting rhizobacteria (PGPR) suggest that these strains protected plants from various pathogens by inducing a systemic resistance (ISR) in plants[9–14]. The evidence for involvement of pseudomonads in ISR was observed when lipopolysaccharides extracted from the outer membrane of *P. fluorescens* caused more accumulation of phytoalexins, increased amount of salicylic acid, phenolics and pathogenesis-related (PR) proteins[9,11,15–17]. Fluorescent pseudomonads have the capacity to exist inside plants endophytically in different host plants[12,18–20]. Previous research carried out also shows that pseudomonads have the potential for the suppression of rice diseases[5,21–24]. The objective of this study was to assess whether the rhizosphere pseudomonads could cause ISR to a fungal disease when applied as infiltration, and to monitor the migration and survivability of genetically engineered strains in the host plant.

Wild type strains of *Pseudomonas putida* V14i and *P. fluorescens* 7–14 used in this study were previously isolated from the rice rhizosphere[21,24]. *Escherichia coli* CE1 was obtained as a gift from R. Jefferson, CAMBIA, Australia. The sheath blight pathogen *Rhizoctonia solani* was isolated from infected rice tissues. LacZY gene cassette was inserted into the chromosome of recipients (7–14, V14i) by a disarmed Tn-7 lacZY transposon through triparental mating[25]. The genetically engineered strains of 7-14gal and V14igal and their constitutive expression of lacZY was stable over 50 generations and were recovered in M9 agar which contains 1% lactose, X-Gal (5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside) and antibiotics (100µg/ml of rifampicin [rif] and ampicillin [amp] for 7-14gal strain and 100 µg/ml of streptomycin [stp] and amp for V14igal strain).

Bacterial strains of 7-14gal and V14igal were grown in M9 at 27°C for 24 h. *E. coli* CE1 strain (negative control) was grown in Lauria Bertani (LB) agar plates at 37°C. These were harvested separately, washed twice with sterile water by centrifugation at 5000 *g* for 10 min and the cell suspension was adjusted to 0.1 OD at 600 nm to obtain 10^9 cfu/ml. Twenty-day-old rice seedlings (cv. IR50) were bacterized by infiltration with 1,2 and 5 µl of bacterial cells with a microsyringe at approximately 2 cm above the soil surface. For *E. coli* CE1, only 2 µl was infiltrated about 2 mm into the stem. In another set of experiment, plants were inoculated by beading needles that were dipped in the bacterial suspension and were slightly brushed into the stem following the method reported earlier by Chen *et al.*[18]. Plants that received 2 µl of sterile water and also uninoculated plants served as controls. The experiments were conducted twice with three replications under greenhouse conditions.

The bacteria were also passively introduced by seed treatment, root-dip and foliar spray onto rice foliage with a bacterial suspension (10^9 cfu/ml) in 1% carboxymethylcellulose (cmc). For seed treatment, bacteria were applied to surface sterilized IR50 rice seeds and were incubated overnight. Excess amount of fluid was drained and it was observed that seeds had 10^9 cfu/g. The treated seeds were sown in pots containing sterile soil. Root dipping was carried out on 21-day-old rice seedlings that were uprooted, rinsed gently in sterile water, and roots were dipped for 30 min in the respective bacterial suspensions before transplanting into sterile soil. When the bacterial suspension was applied also as foliar spray on 15-day-old rice seedlings (IR50), the treatment was made until minute droplets appeared on both surfaces of the entire leaf. Rice seedlings that received plain cmc solution as spray served as control.

The survival of bacteria was monitored by removing 2 cm sections of the rice stem (1 cm above and 1 cm below the point of infiltration). To assess the movement of bacteria from the point of infiltration, 2 cm long

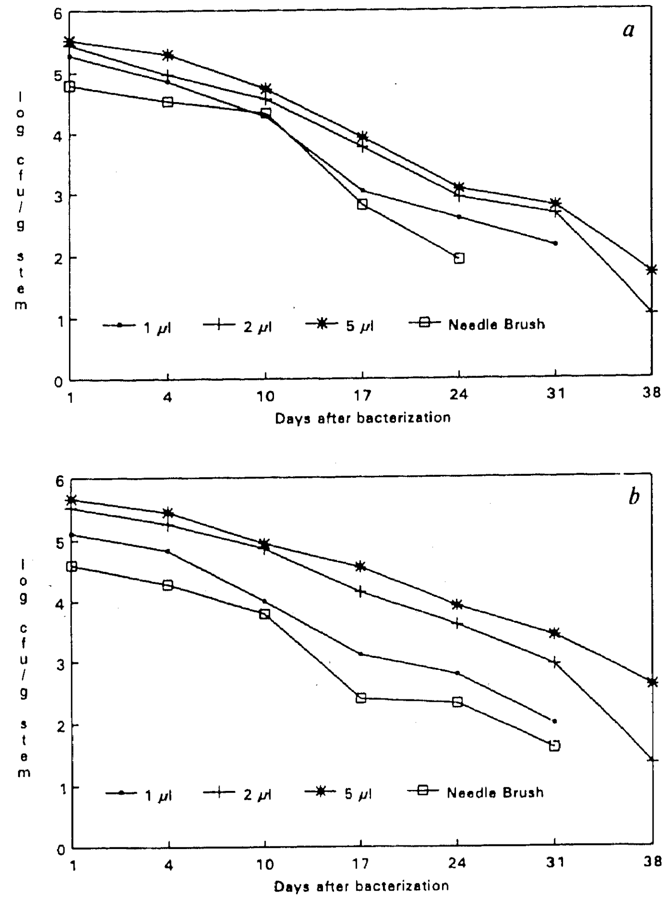

Figure 1. Survival of lacZY-marked bacterial strains after infiltration and needle brush application into the rice (cv. IR50) stem. (*a*), *P. putida* V14igal; (*b*), *P. fluorescens* 7-14gal.

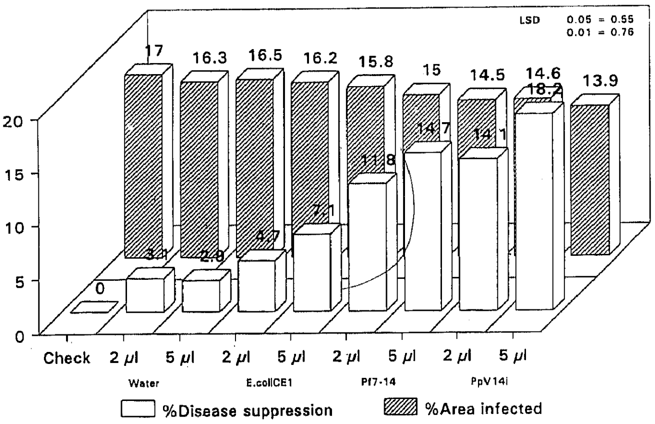

Each value is mean of three replications

Percent area infected = Lesion length/plant height x 100

Percent disease suppression = 100 - treatment/control x 100

section was also sampled (1.5–3.5 cm [I stage] and 4–6 cm [II stage]) above the point of infiltration. The samples were weighed, rinsed for 5 min in running tap water and then were soaked for 2 min in 2% sodium hypochlorite solution. Subsequently, they were washed thrice in sterile water and were triturated in 1 ml of 0.01 M phosphate buffer (pH 7.1). Plants were sampled at 1, 4, 10, 17, 24, 31 and 38 days after the bacterial infiltration. Endophytic presence of bacteria was assessed in 1 g of rice roots removed from 10 and 15-day-old seedlings that received seed treatment or root-dip treatment or from 1 g of leaf sample in the case of foliar spray (5 and 10 days after bacterization) treatment. Appropriate serial dilutions of the triturated samples were plated on to triplicate agar plates of KB (King's B) with X-Gal with or without cycloheximide (40 µg/ml) for 7-14gal and V14igal strains. Samples that received *E. coli* CE1 strain were plated on LB agar with X-Gal and samples of untreated checks were plated on KB/LB agar plates. After 48 h of incubation, the blue coloured bacterial colonies were counted (7-14gal and V14igal were also observed under UV lamp at 365 nm for their fluorescent character) and their cfu/g of tissue was determined.

A field experiment for the systemic suppression of rice sheath blight (ShB) was conducted by planting surface sterilized rice (IR50) seeds in a randomized complete block design. Rice seedlings of 20–22-day-old were infiltrated with 2 µl and 5 µl of 10^9 cfu/ml of 24 h grown wild type 7-14, V14i and CE1 strains. Control plants received plain sterile water or did not receive any treatment (untreated checks). One day after the bacterial treatment, the plants were inoculated with *R. solani*. Inoculum of *R. solani* has been described previously[23] and was applied at the rate of half a teaspoon per hill close to the sheath portion of the rice plants. ShB severity rating was recorded on the 10th day after *R. solani* inoculation from randomly selected 10 rice plants per plot (0.5 × 0.5 m)/treatment. From these assessments, per cent disease incidence and per cent disease control were determined by statistical analysis.

The data on the survival of the two marked strains of *P. putida* V14igal and *P. fluorescens* 7-14gal are presented in Figure 1 *a*, *b*. These data show that bacteria survived up to day 38 when 2 µl or 5 µl aliquots were infiltrated. Whereas bacteria applied in a needle brush did not survive beyond 24 days (V14igal) or 31 days (7-14gal) after the treatment. The *E. coli* CE1 was detected up to 10 days after infiltration or needle brush treatment. In water treatment or nontreated control tissues, blue-coloured colonies did not develop.

Upward migration of the marked strains of V14igal and 7-14gal occurred up to 6 cm (stage II) away from the point of infiltration in the rice sheath or stem (Table 1). Beyond this point the stem and the leaves did not

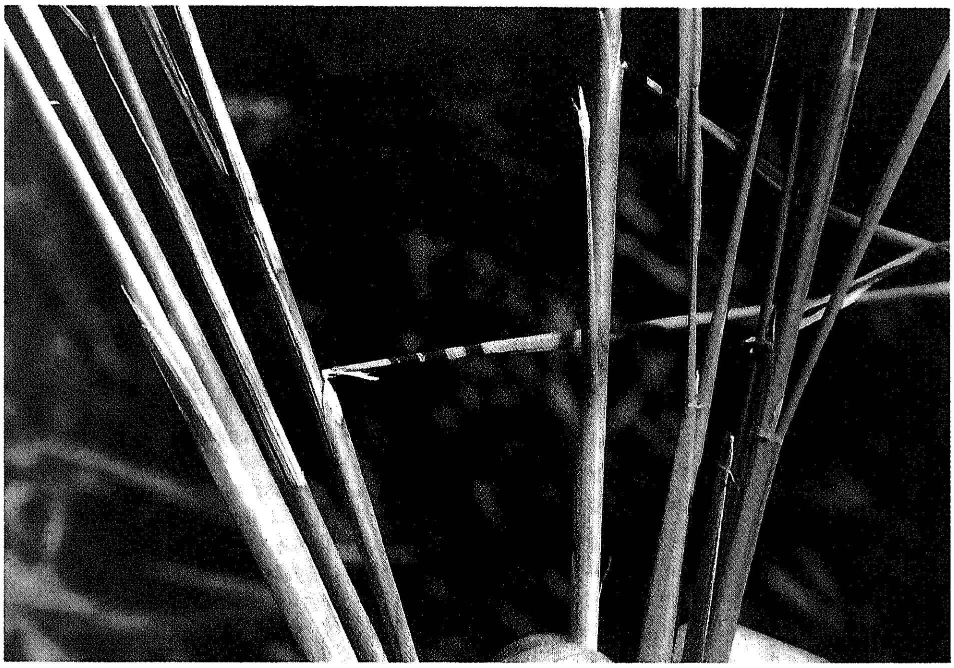

Figure 3. Reduction of sheath blight in IR50 rice plants due to the induction of systemic resistance by *Pseudomonas putida* strain. *Right*: Plants infiltrated with 5 µl of PpV14i strain; *Left*: Nontreated control plants infected with *R. solani*.

have the cells of the marked strains. However, below the point of infiltration these bacteria were detected at 57 cfu/g tissue (V14igal) and 39 cfu/g tissue (7-14gal) from day 10 after infiltration.

From the results there is no indication for the endophytic presence of the marked strains of bacteria in roots of seedlings that were raised from bacteria-treated seeds. There was also no endophytic presence of bacteria in leaf sample of rice seedlings that received foliar sprays of V14igal and 7-14gal. Bacteria applied as a root-dip were detected at 23 cfu/g root in V14igal treatment.

Figure 2 shows that *Pseudomonas* strains (V14i and 7-14) present in the rice stem reduced the sheath blight incidence by 18 and 15% in comparison with infected control, which is taken as 100% infection. Yet these bacteria were not present on the surface of the sheath or pseudostem. In spite of the absence of bacteria on surface of the rice plant there is evidence for pathogen suppression by bacteria (Figure 3). This is most likely due to the induced systemic resistance triggered by the endophytic bacteria introduced into the rice stem. The results indicate that there is a minimal reduction of ShB even with *E. coli* CE1 or by water infiltration. This might be due to the response of plants to lipopolysaccharides or other defence-inducing signal factors. This is the first report on the induction of induced systemic resistance (ISR) in rice by the rhizosphere-bacteria. Our future studies will be directed to analysing the nature of the defence substances (phytoalexins, salicylic acid or other PR proteins) involved in the induced systemic resistance in rice.

Litomosoides carinii and *Acanthocheilonema viteae* in rodents: The influence of nonspecific immunosuppression on establishment of filarial infection

Nigar Fatma, Amita Shukla-Dave and R. K. Chatterjee

Division of Parasitology, Central Drug Research Institute,
Lucknow 226 001, India

Prolonged incubation period and poor establishment rate of adult filarial parasites in experimental host have jeopardized much of laboratory investigational activities. Study was therefore planned with the objectives of shortening the prolonged incubation period of filarial infection and enhancing the establishment rate of macrofilariids with high peripheral microfilaraemia in host. It was observed that cortisone treatment in rodents at 10 mg/kg, subcutaneously from day –7 to day + 7 in two courses at week's interval, not only reduced the prepatent period of both *Litomosoides carinii* and *Acanthocheilonema vitae* infections by 10 days but also increased the adult worm recovery to a significant extent. Microfilarial level remained higher in cortisone-treated animals throughout the observation period. It was also interesting to note that length of adult male and female filariids (*A. viteae*) recovered from treated animals was significantly more in comparison to controls. The carbohydrate metabolism of recovered parasites from cortisone-treated hosts remained unaltered and thereby, remained suitable for various experimental purposes.

THE influence of immunosuppression of host on establishment of parasite infection is well documented[1–5]. Treatment with immunosuppressant leads to increased growth rate and size of parasites by counteracting the host's natural resistance towards parasite establishment mechanism. The present study was therefore designed with the objectives of lowering the prolonged prepatent period and increasing the intensity of microfilaraemia through higher establishment rate of adult filariids by suppressing the host's immune system with cortisone, an immunosuppressant[6–10]. The study was also extended to assess the metabolic status of recovered adult filariids from cortisone-treated animals to ascertain their physiologic status.

Two rodent filarial infections, *Litomosoides carinii* in cotton rat (*Sigmodon hispidus*)[11,12] and *Acanthocheilonema viteae* in *Mastomys coucha*[13,14] were used in the study.

Hydrocortisone (Sigma) was used initially at different dose levels (5, 10 and 20 mg/kg, s.c.) and courses (5 or 10 consecutive days or in two courses with a week's interval) in cotton rat and mastomys to determine the optimum dose level to bring about desired immunosuppressive effect as revealed by performing macrophage migration test[15,16]. The dose of 10 mg/kg × 5 days followed by another course preceded by a gap of one week was found optimum. Microfilaraemia was monitored till 75 of infective exposure of all treated and control animals by examining 5 cmm of tail blood. Animals were sacrificed on day 75 and worm burden was ascertained according to the method of Chatterjee *et al.*[12]. Length of recovered male and female parasites was also measured. The contents of uteri of female parasites were examined for any abnormality in developmental stages and microfilariae. The glucose metabolism[17–19] of parasites recovered from cortisone-treated hosts was measured by assessing *in vitro* uptake and lactic acid production capabilities.

In cortisone-treated animals, microfilariae of *L. carinii* and *A. viteae* appeared initially in peripheral blood of some animals on day 45 of L_3 exposure, i.e. 10 days earlier than control animals, as monitored by blood examination for microfilaria at 5 days interval since day 30 of L_3 exposure. The per cent positivity for microfilariae on day 45 was 97.5% in case of *A. viteae* and 66.0% in case of *L. carinii*-infected animals. On day 50, all the cortisone-treated groups of animals were microfilariae-positive. The intensity of microfilaraemia in treated animals was higher ($P < 0.001$) throughout the observation period (Figures 1 and 2). Per cent recovery of adult *A. viteae* was also higher (70%) in comparison to controls (32%) (Figure 2). In case of *L. carinii* infection, the number of adult parasites recovered from treated hosts was more (28 ± 3.5) in comparison to control animals (18 ± 3.0) (Figure 1). All female parasites (both *A. viteae* and *L. carinii*) contained normal and active developmental stages in the uteri. It was

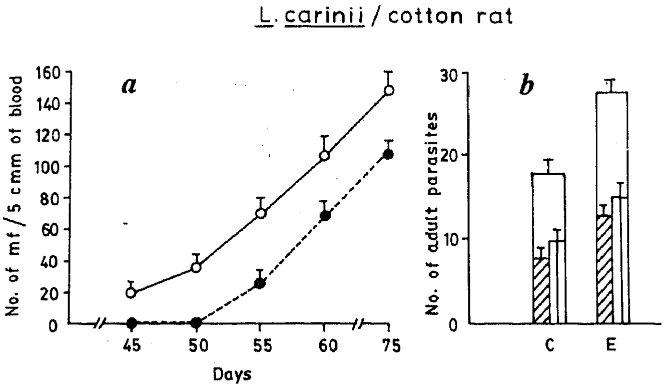

Figure 1. Microfilaraemia (*a*) and adult worm recovery (*b*) from cotton rats infected with *L. carinii*. o– – –o Cortisone treated; •– – –• Untreated control. ▨Male, ▥ Female, □Total. E, Experimental; C, Control.

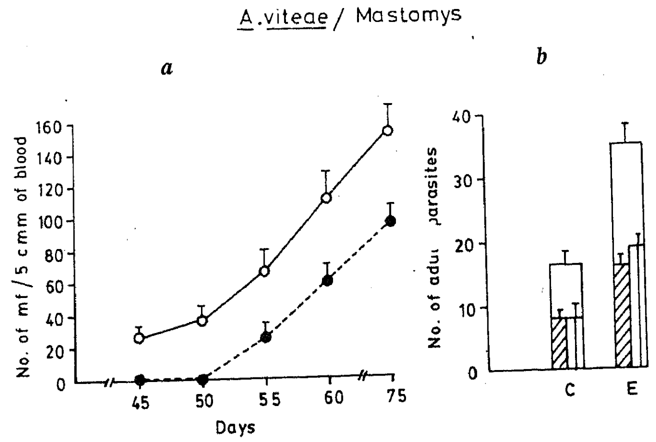

Figure 2. Microfilaraemia (*a*) and adult worm recovery (*b*) from Mastomys with *A. viteae* infection. ○---○ Cortisone treated; ●---● Untreated control. ▨ Male, ▥ Female, ☐ Total. E, Experimental; C, Control.

interesting to observe that adult male and female *A. viteae* recovered from cortisone-treated animals were longer in length than their counterparts of control animals. Lengths of female and male parasites were 8.3 ± 3.0 and 3.4 ± 0.24 cm respectively whereas worms from untreated animals were respectively 5.4 ± 3.0 and 2.7 ± 0.22 cm. No such difference in length of *L. carinii* adults could be detected when recovered from cortisone-treated animals.

The glucose uptake of adult *L. carinii* and *A. viteae* from control animals was respectively 0.64 ± 0.06 and 0.49 ± 0.10 μmole/mg worm which was well comparable to worms obtained from their respective cortisone-treated hosts. Similarly there was no difference in the level of lactate production in cortisone-exposed parasites of both the species.

Our present study with experimental filarial infections using cortisone in rodent hosts indicates that nonspecific immunosuppression can promote significantly the per cent establishment rate of adult filariids, increase in size of worms and even causes reduction in the prolonged prepatency period. Hydrocortisone is well known to interfere with a variety of intra- and extra-cellular activities of mononuclear phagocytes, diminish monocyte chemotaxis and inhibit migration of leucocytes[20]. The decisive role of T-cell activity in establishment of helminth infections has been demonstrated earlier using athymic mice[21,22] or by transfer of immunity by T-lymphocytes[23,24] or hydrocortisone, a well-known T-cell suppressant[25]. Nevertheless, timing for application of immunosuppressor is important in case of filarial infection in which various developing forms take different time periods for maturity depending upon the species of parasite as well as host and the total incubation period may vary from 2 to 8 months. Keeping these in view, the course of treatment of cortisone is broadly divided into two time periods coinciding with the stages of larval forms, i.e. from L_3 to preadult stages so that all the developing forms may take the advantage of immunosuppressive state of the host. Thus, based on larval development cycle of *L. carinii* and *A. viteae*[26], two courses of cortisone, each of five days duration were administered to produce sustained immunosuppressive effect during the course of establishment period of parasites.

Both the species of parasites showed significantly higher per cent establishment rate in their respective hosts and in one of the species (*A. viteae*), the average length of females ($P < 0.001$) and males ($P < 0.01$) was also significantly higher than their counterparts from untreated control mastomys. Moss[2] has demonstrated that *Hymenolepis microstoma* in mice treated with cortisone grows larger than in control mice, and suggested that the increased growth of worms may be due to the combined effects of immunosuppression and growth promoter, which may be a hormonal growth-stimulating factor.

It is interesting to mention that whereas nonspecific immunosuppression of host helped in better establishment rate of adult parasites, immunostimulation on the contrary reverses the situation[6,7]. Thus, immunomodulation whether suppressive or stimulatory has in general a significant role to play in establishment of filarial infection in host.

The two other parameters as observed to be altered in both *L. carinii*/cotton rat and *A. viteae*/Mastomys systems following cortisone treatment are lowering of prepatency period of 10 days and increased intensity of microfilaraemia. Lowering of prepatency period appears to be due to increased growth rate of larvae in immunosuppressed host whereas higher intensity of microfilaraemia in cortisone-treated animals happens to be due to increased worm population.

Glycolysis is the major energy-generating pathway and both *L. carinii* and *A. viteae* recovered from cortisone-treated hosts, rapidly absorbed glucose from the medium and lactate was synthesized as the major end-product. Estimation of glucose uptake and lactate production of filariids showed parasites to be metabolically normal.

In conclusion, it may be stated that nonspecific immunosuppression of experimental host leads to lowering of prepatency period, higher intensity of microfilaraemia and increased population of physiologically normal filarial parasites. The data shown in this study would be of great help in laboratory maintenance of filarial infection and for meeting the growing demand of filaria parasite material for various experimental purposes.

Block rotation in a part of eastern Dharwar craton of South India – A suggestion from aeromagnetic data interpretation

Ch. Rama Rao, D. S. Bhaskara Rao and D. Atchuta Rao

National Geophysical Research Institute, Hyderabad 500 007, India

Deformation in the brittle part of the earth's crust often gives rise to faults. It is believed that these faults tend to form conjugate fracture systems, and the rigid crustal blocks bounded by these fractures rotate about horizontal axes in the event of dip slip and about a vertical axis in the strike slip environment. Recent studies in the granite–greenstone terrain of a part of eastern Dharwar craton in South India (3.4–2.5 Ga) have suggested a tectonic environment in which the cross cutting NW, NE and ENE trending faults systems divided the crust into a mosaic of rigid crustal blocks which might have been rotated. Analysis of the aeromagnetic data of a part of this area suggests that (i) the NW–SE trending shears have strike-slip component, (ii) the rigid crustal blocks have rotated through an angle of 8.5° clockwise and (iii) the depth of the decoupling zone beneath the strike-slip faults is estimated to be 3.0 km, i.e. it is in the upper crustal level.

UNDER a variety of tectonic conditions the brittle part of the earth's crust is often prone to deformation. This deformation generally gives rise to faults. Simultaneous translation and rotation of fault-bounded crustal fragments, which are governed by kinematic constraints, are widely reported in varied geological and tectonic settings[1–4]. Fault-bounded crustal blocks rotate about vertical axes, where a fault slip has a strike parallel component[1,5,6], and on horizontal axes where dip slip occurs. Faults also rotate under continued deformation. These block rotations may occur (i) in discrete shear zones, (ii) zones of distributed shear probably caused by oblique subduction, (iii) during accretion, (iv) due to oroclinal bending, and (v) in overthrust faulting[2]. Such rotation may take place in different scales, starting from an outcrop to regional scale[5,7,8]. Recent studies on the granite–greenstone terrain of a part of Eastern Dharwar craton of south India, based on Landsat, aerial photos, age relationships of the structures such as faults, lineaments, dykes, etc. and on field evidences, suggested that tectonically this area is a composite mosaic of crustal blocks of various dimensions. These have rotated about vertical axes in geological time in response to various tectonic processes[9]. Several workers have reported palaeomagnetic, seismic and structural evidences in support of block rotation[2,4,10–17].

The angles through which the blocks can rotate are, in some cases 15–20°, and in some other cases the horizontal rotations are reported to be 70° and even more between the two parallel faults in strike slip environment.

Aeromagnetic data and its interpretation can be utilized for (i) geological mapping, (ii) spotting of mineralized zones, and (iii) unravelling of structural elements like fault/shear zones, dyke swarms, and their alignments and extensions, boundaries of basinal and domal features. Aeromagnetic data can also be used to identify strike slip movements, rotational patterns, etc. and help in deriving basement configurations, thereby in the understanding of the structural evolution of different crustal domains. Here, we present a structural and tectonic scenario, derived from the interpretation of a small portion of the aeromagnetic data to look for terrains suggesting block rotation.

The study area forms a small portion of the granite greenstone terrain in Eastern Dharwar craton situated to the west of the Proterozoic Cuddapah basin. This area is bounded by 14°25′0″ and 14°35′0″N lat., and 77°30′0″ and 77°55′0″E long. (Figure 1 *a*).

The Archaean granite–greenstone terrain west of the proterozoic Cuddapah basin is a low to medium grade terrain, consisting of steeply dipping green schist belts, often invaded by highly elongated ‘granitoid bodies’. The terrain is traversed by NW, NE and ENE trending Precambrian dykes[18]. Dykes of younger ages traversing in other directions are also there. Quartz reefs are mostly emplaced along NW trending shear zones in this part of the area. A comprehensive geological history of this area is provided by Raju *et al.*[19]. The aeromagnetic lineaments in this area mostly represent dyke systems and fault domains. Two NW–SE trending parallel fault/shear zones, viz. the Hampapuram and Kandukuru faults (Figure 1 *b*) are cut by ENE trending faults, often occupied by ENE trending dykes. Quartz reefs are emplaced in both the fault/shear zones. Cataclastic and brecciated rock matrix are present in these two fault/shear zones. Displacement of dykes indicates a possible right lateral movement along the faults[9]. The aeromagnetic data for this belt has been reprocessed to infer structures, if any, related to the faults/shears and to bring out the tectonic history *vis-à-vis* the proposed block rotation hypothesis.

The National Geophysical Research Institute (NGRI) in collaboration with the Geological Survey of India (GSI) carried out an airborne magnetic survey for mineral exploration during 1980–82 over a part of the Eastern Dharwar craton and part of the Proterozoic Cuddapah basin, at a flight height of 150 m with a flight line spacing of 0.5 km in some selected areas and with a line spacing of 1 km in most of the area. The area under study (Figure 1 *a*) forms a small part of the aeromagnetic map on the Archaean basement complex.

The total intensity aeromagnetic anomaly field data of the study area have been reprocessed, and high-pass and low-pass filtered anomaly maps have been prepared using the MAGMAP software of Paterson, Grant and Watson Ltd., Canada. Reduced to equator (RTE) option has been applied on the above high-pass and low-pass filtered maps. These are shown in Figures 2 *a* and 3 *a* respectively. This option has been preferred because: (i) the high-pass filtering accentuates the shallow magnetic features at the expense of the broader and deep-seated sources, and allows one to identify easily the various shallow magnetic trends, (ii) the centres of the magnetic lows and/or highs in the RTE map clearly locate the tops of the sources. The low-pass filtered RTE map has been analysed to identify the possible downward continuity of the shallow structural features.

Aeromagnetic interpretation helps in recognizing long linear features like faults/shears, dykes and other structural lineaments. Offsets in continuity of the magnetic

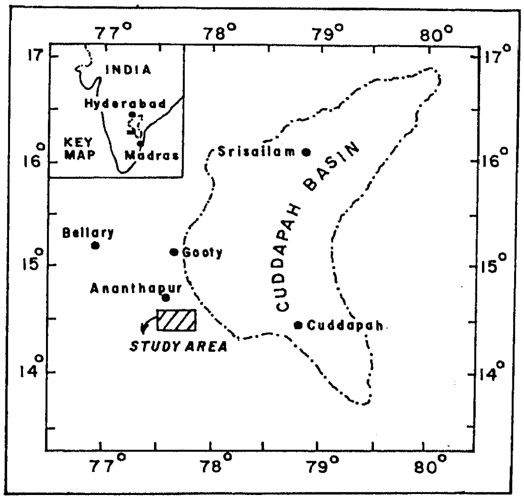

Figure 1 *a*. Location map of the study area.

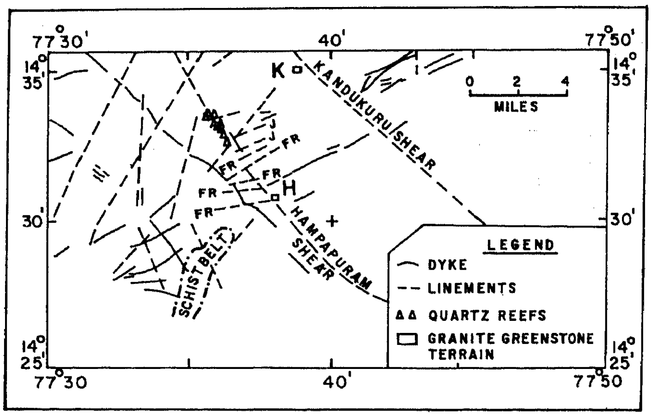

Figure 1 *b*. Geological map of the study area.

trends/lineaments, abrupt terminations of magnetic lows and/or highs, drag features, contour nosings, alignments of lows or highs, etc. are some of the direct indicators of fault/shear zones[20]. A persistent offset in the magnetic trends and drag features on either side of a fault/shear zone indicates the possibility of strike slip environment, even though large scale strike slip faults do not leave any morphological evidence for strike slip faulting.

The low geomagnetic latitudes such as the present area, an intensely sheared tectonic zone with a possibility of depletion and/or destruction of magnetic minerals occurring, can be identified by the characteristic positive magnetic anomaly closures all along the shear zone.

Using the above criteria, the aeromagnetic anomaly map of this area has been interpreted and lineaments, dislocation planes, possible shear/faults, etc. identified. The interpreted structures are shown in Figures 2 *b* and 3 *b*.

Two major structural elements that are dominant and striking on the map are the NW–SE trending Hampapuram fault/shear in the west and the Kandukuru fault/shear in the east. A number of ENE and EW trending magnetic lineaments, mostly representing fault/shear zones, often occupied by dykes, are also seen cutting across the NW features, thus forming a domain of fault system. The NNE–SSW trending magnetic anomaly feature represents the extended portion of the Hagari–Ramgiri schist belt. A general observation is that there are fault zones both in the north and south bounding the Hampapuram and the Kandukuru fault/shear zones. The ENE and EW features are found to have been offset by the NW faults. The extent of offsets are shown as d1, d2, d3, . . . in Figure 2 *b*.

Shifts in the NE and ENE trending magnetic anomaly

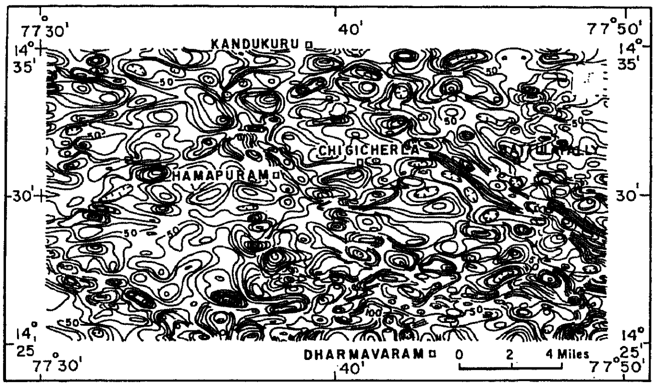

Figure 2 *a*. High-pass filtered, reduced to equator total intensity aeromagnetic anomaly map of the area (cont. interval 10 nT).

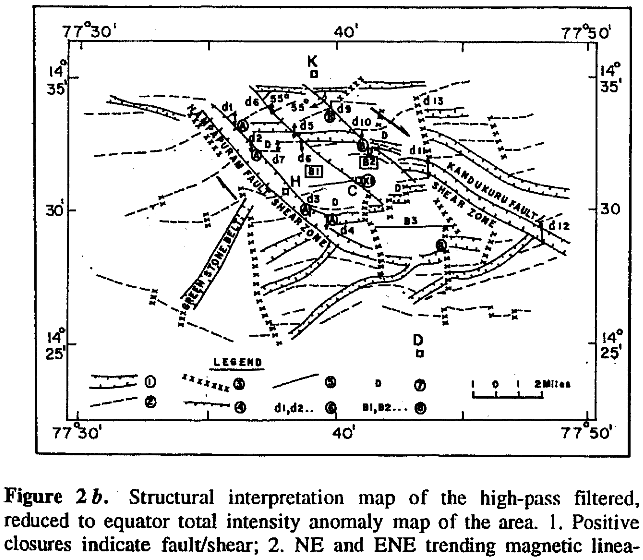

Figure 2 *b*. Structural interpretation map of the high-pass filtered, reduced to equator total intensity anomaly map of the area. 1. Positive closures indicate fault/shear; 2. NE and ENE trending magnetic lineaments; 3. Dislocation planes; 4. Possible fault traces within the block; 5. Inferred extensional fractures; 6. Extent of displacements along shears; 7. Drag features indicate strike slip movement; 8. Inferred rigid crustal blocks bounded by shears.

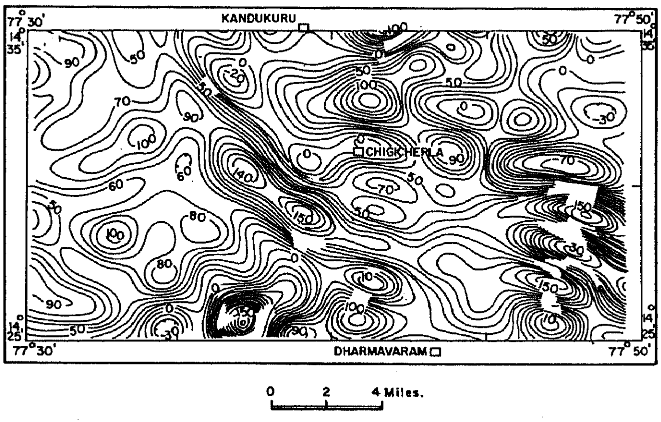

Figure 3 *a*. Low-pass filtered, reduced to equator total intensity aeromagnetic anomaly map.

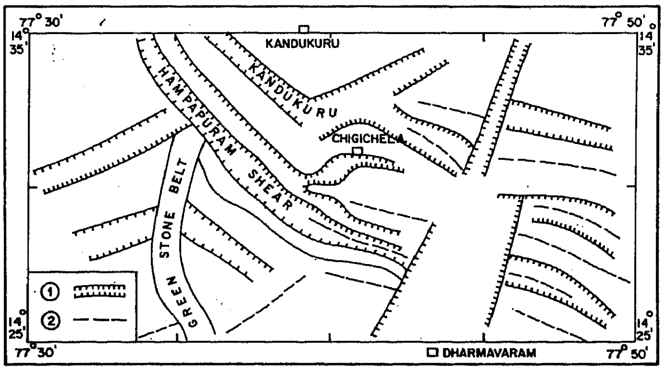

Figure 3 *b*. Structural interpretation map of the low-pass filtered, reduced to equator total intensity aeromagnetic anomaly map of the area. Note the existence of both the Hampapuram and Kandukuru fault/shear even at deeper levels.

trends (Figure 2 *b*), designated as 'A' on either side of the NW–SE trending Hampapuram fault and 'B' on either side of the Kandukuru shear zone and the drag features 'D', indicate strike slip movement. These shifts in the anomalies can be attributed to a right lateral movement along the shear zones. Field and other evidences also confirm right lateral movement in regional scale[9]. The positive magnetic anomaly closures as shown in the figure, are associated with intense shearing. Continued tectonic activity in this part of the craton has resulted in a sygmoidal shearing as well as rotational features in the faults (as indicated by arrows in the Figure 2 *b*). Thus, interpretation of this map led us to identify rigid crustal blocks B1, B2 and B3 bounded on all sides by strike slip faults which probably caused the blocks to rotate. Occurrence of kimberlite intrusion at one of the corners in the blocks B1 (shown as k1) seems to have been owing to a possible extension due to rotation in this corner. A clockwise rotation of the blocks owing to the strike slip is envisaged in this part.

Figure 3 *b* is the structural interpretation map of the low-pass filtered, reduced to equator data. This interpretation further supports the continuation of the two shear zones vertically downwards. The log normalized radially averaged power spectrum (Figure 4 *a*) computed for the low-pass filtered map gives an average depth of 3.0 km for a possible magnetic marker horizon. This depth, perhaps, represents the depth to a mid-crustal disharmony beneath the strike slip fault system[21]. Thus, geophysical inferences suggest a region of block rotation in which the blocks are surrounded by deformed rock matrix. Based on these structural inferences, a block diagram showing the possible strike-slip and block rotation in this region is presented in Figure 4 *b*.

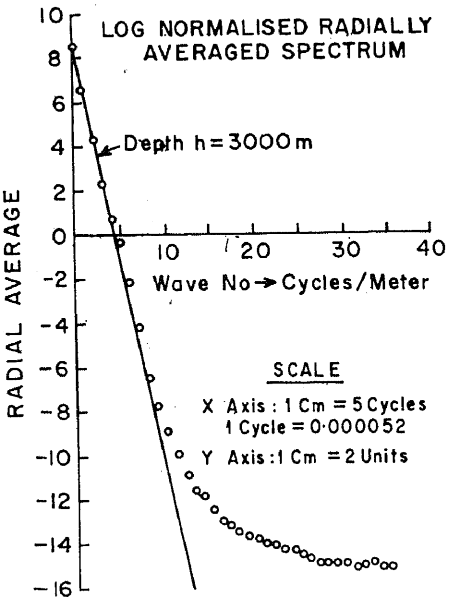

Figure 4 ***a*****.** Log-normalized radially averaged power spectrum computed for the low-pass filtered aeromagnetic anomaly field data. $h = 3$ km. Possibly indicates the depth to the mid-crustal disharmony beneath the shears.

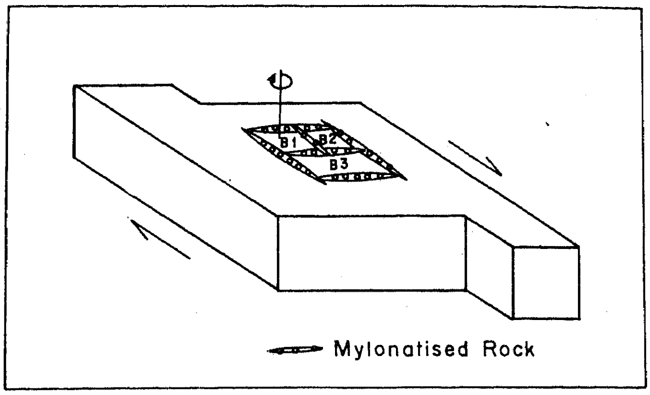

Figure 4 ***b*****.** Interpreted block diagram showing the inferred crustal blocks B1, B2 and B3 surrounded by the cataclastic and brecciated rock matrix.

An attempt is made here to calculate the angle of block rotation using the relation given by Nur *et al.*[22]

$$d = W \sin\phi\, [\sin\alpha \times \sin(\alpha - \phi)]^{-1}, \qquad (1)$$

where d is the displacement along the fault, W the width of the faulted block, α the initial angle between the faults and the boundary of the domain and ϕ the block rotation angle.

The displacement d is measured from the interpreted section. The average of the horizontal displacements on either side of each fault (here the displacements $d1$, $d2$, etc. between A's B's on either side of the faults) represents the strike-slip displacement along the faults.

The initial angle is the angle between the fault and the boundary as shown in the figure, and the width w is the average distance between the two faults.

Here $d = 680$ m (average displacement), $w = 3165$ m (Block 1), $w = 2850$ m (Block 2).

Substituting these values from the interpreted section, the angle ϕ is calculated from equation (1) and is 9.0 and 8.0 degrees clockwise for blocks 1 and 2 respectively.

Interpretation of a part of aeromagnetic data from a region of strike-slip movement in a Precambrian granite greenstone terrain, has resulted in identifying a zone of possible block rotation. The average angle of block rotation is determined from the width w, initial angle α and the displacement d measured from the interpreted map, using the relation given by Nur *et al.*[22] and is 8.5 degrees clockwise. Computation of the radial power spectrum from the low-pass filtered aeromagnetic anomaly data of this area, has given an average depth to a possible magnetic marker horizon at a depth of 3.0 km. This probably represents the depth to the decoupling zone in the upper crustal level below the shear zone.

Statistical analysis of glaciers in Himachal Pradesh, north-west Himalaya, India

D. P. Dobhal and Surendar Kumar

Wadia Institute of Himalayan Geology, Dehradun 248 001, India

A statistical analysis of Himachal glaciers has been carried out. The maximum concentration of glaciers is in the elevation range 4500–5500 m. More glaciers are of transverse simple type than longitudinal type.

THE Himalaya, on the southern slopes of the Tibetan plateau, is one of the most important glacier systems on the earth. The main snow-gathering ground is in the higher Greater Himalayan ranges, whose relationship with climate changes on various time scales indicates topographic and climatic conditions favourable for the formation of the glaciers. The present work is in continuation of our glacier inventory[1].

The study area is situated in the western part of the Himalaya, extending about 315 km between UP Himalaya in the east and the Kashmir Himalaya in the west (Figure 1). It encompasses mountain area of about 48,034 km^2 out of the total land area of 55,673 km^2 of the Himachal Himalaya. It is estimated that 9.4% (approximate 10%) is glaciated area of 4516.22 km^2 out of the total mountainous area of 48,034 km^2. Every 1 km^2 of the land area is glaciated to the extent of 0.09 km^2. Six hundred one glaciers have been identified in six drainage basins[2], Chandra–Bhaga (200), Beas–Parbati (80), Ravi (54), Malung (40), Spiti (159) and Satluj (68). Statistical analysis of glaciers in these drainage basins has been carried out on the basis of earlier works[2–8].

Glaciers are unevenly distributed between the Great Himalayan, Pir-Panjal and Dhauladhar ranges, controlled by the topographic variation and the amount of precipitation in the region. The altitude increases from NW to SE, where maximum precipitation occurs. So, the Satluj basin, which receives more precipitation and is at higher elevation, remains covered with snow for longer duration than the other basins. In this study the identification of glaciers is from LANDSAT imagery. Data for the glaciers are summarized in Tables 1 and 2.

In Chandra–Bhaga, Spiti and Satluj basins the highest frequency of glaciers is in the length range 2–4 km, while in Beas–Parbati, Ravi and Malung basins the highest frequency is around 2 km (Figure 2 *a*). It is also observed that 35% of the glaciers fall in the range 2–4 km in length, 55% are around 5 km, and the remaining 10% are 10 km or more in length. Bara-Shigri is the longest glacier (29 km) of the Himachal Himalaya.

The area covered by individual glaciers was calculated by digital planimeter. Figure 2 *b* shows that majority of the glacial cover area of Himachal extends over 2 to 6 km^2, but some glaciers are more than 10 km^2 in area. An examination of Table 1 shows that the Chandra–Bhaga, Malung and Spiti basins are relatively balanced in basin area and glaciated area, while the Beas, Ravi and Satluj are less glaciated compared to the basin area. The glaciers in NW Himachal Pradesh are bigger than those in the SE region.

Broadly the glaciers have been classified into two main types (i) Longitudinal and (ii) Transverse, on the basis of their flow direction[3]. These are further subdivided into simple and compound types. Simple glaciers have a single accumulation zone while compound glaciers have two or more accumulation zones in a single basin.

About 69.5% of the Himachal glaciers are of transverse simple (TS) and compound (TC) types and 30% are of longitudinal simple (LS) and compound (LC) types. The largest class of glaciers is the transverse simple (TS) type (Figure 3) while longitudinal glaciers are fewer, and occupy wider valleys and are larger in size. The distribution of transverse and longitudinal glaciers in different basins is, respectively:

Chandra–Bhaga,	67 and 33%;
Beas–Parbati,	74 and 26%;
Ravi,	58 and 42%;
Spiti,	65 and 35%, and
Satluj,	75 and 25%.

Glaciers in Malung basin are of only transverse type. It is well known that the orientation (flow direction)

Table 1. Number of glaciers identified in different basins

Basin	Basin area (km^2)	Glaciated area (km^2)	No. of glaciers	Average size (km^2)	Ratio between basin and glaciated areas
Chandra–Bhaga	7510	1778.98	200	8.89	4.22 : 1
Beas–Parbati	14,070	729.59	80	8.03	19.28 : 1
Ravi	5154	340.97	54	6.03	15.10 : 1
Malung	1570	231.86	40	5.78	6.77 : 1
Spiti	5440	1151.12	159	7.23	4.30 : 1
Satluj	14,290	283.70	68	4.17	50.00 : 1
Total	48,034	4516.22	601		

Table 2. Summarized statistics for the glaciers in six basins

Parameters	Chandra–Bhaga	Beas–Parbati	Ravi	Mulang	Spiti	Satluj
Total basin area (km^2)	7510	14,070	5154	1570	5440	4290
Glacierized area (km^2)	1778.98	729.59	340.97	231.86	1151.12	283.70
Glacierized area % of basin area	23.60	5.19	6.62	14.77	21.16	1.99
No. of glaciers	200	80	54	40	159	68
Length						
a) >5 km	40	16	07	07	15	03
b) <5 km	160	64	47	33	144	65
Types						
Longitudinal	66	21	23	–	56	17
Transverse	134	59	31	40	103	51
Largest glacier						
Length (km)	29	17.50	9.00	5.5	10.00	6.50
Area (km^2)	157	82.00	18.75	13.8	26.63	15.54
Elevation						
Maximum (m)	6200	5500	5400	6000	6000	6000
Minimum (m)	4000	4000	4000	5000	5000	5000

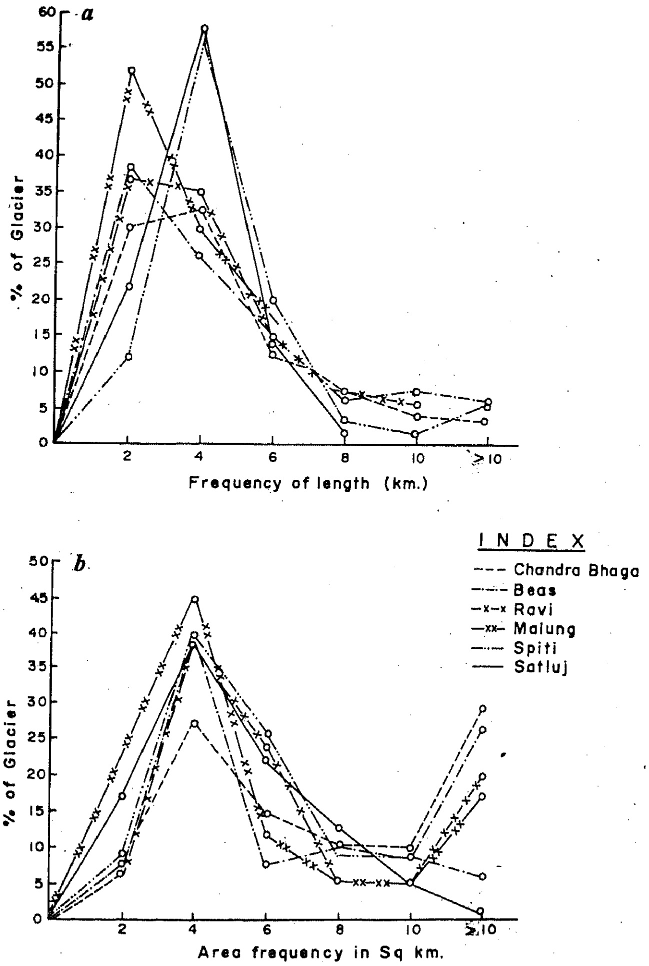

Figure 2. Frequency diagram of (*a*) length vs glacier % and (*b*) area vs glacier %.

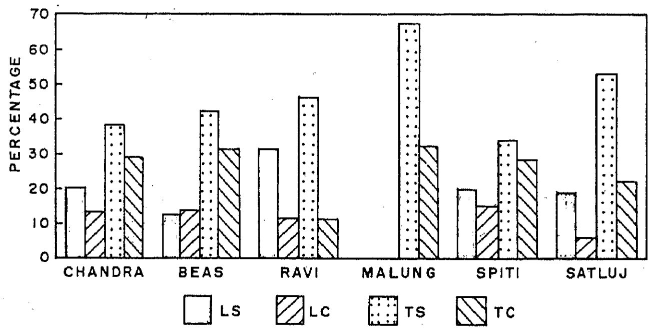

Figure 3. Distribution of glacier types in different basins.

of the glacier is controlled by topographical slope of the region. Most of the Himalayan glaciers are oriented N–S whereas valleys are mostly E–W or parallel to the orographic trend of the Himalaya. In Himachal Pradesh the orientations of identified glaciers have been determined and rose diagrams prepared on the proportion of glacier catchment in sixteen compass sectors (Figure 4). Glaciers in Chandra–Bhaga, Spiti, Malung and Satluj are mostly northward oriented (> 50%), while the majority of glaciers in Beas–Parbati and Ravi basins are southward. It is also observed that glaciers with northward orientation are longer and cover larger area, for example Bara Shigri (29 km covering 157 km^2), Mujrilangang (13.75 km covering 30.7 km^2) and Chhota Shigri (9 km, covering 8.75 km^2); southward glaciers are smaller in length, cover less area and are steeper.

The maximum concentration of the glaciers is between 4500 m and 5000 m altitude, while a few of them extend down to 3800 m. The lower limit (snout position) of

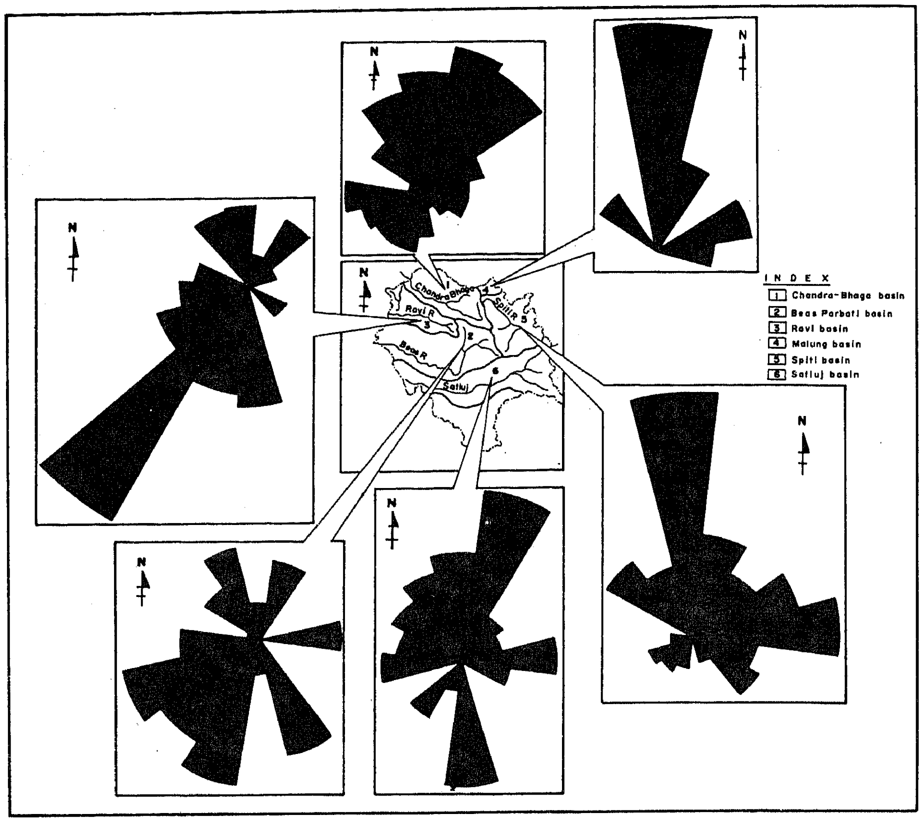

Figure 4. Glacier orientation in different basins of Himachal Pradesh.

the glacier fluctuates between 4000 and 5000 m in different basins. The orientation of the glaciers depends on the topographic conditions and the orographic control of the mountain. Thus orientation is spread over in all directions, with main concentration northward (58%) and southward (32%).

The slope/gradient of the glaciers varies between 3 and 33 degrees, but sometimes sudden increase in slope gives the evidence of surging or ice cliff on the glacier body. Where the slope is more the snow does not stand longer. Such glaciers can be considered as hanging glaciers and become vulnerable to avalanches and other glacier hazards.

Glacier development in a terrain is dependent on the topographic and climatic conditions of the region. Study of glacier development is useful for understanding present and past climatic and environmental changes. Statistical comparison of higher latitude glaciers with lower latitude glaciers (Himalayan type) can give an idea and correlation of control of precipitation and palaeoenvironment.

Knot Theory and its Applications. Kunio Murasugi. Birkhäuser Verlag AG, Klasterberg 23, PO Box 133, CH–4010, Basel, Switzerland. 1996. Pages 323. SFr 98, DM 118.

Even though mankind has been using knots ever since the dawn of civilization, the so-called theory of knots which came into existence as a special branch of three-dimensional topology is approximately only a hundred years old. It had some reasonable initial development followed by a slow growth for a few years. And then, with its multifarious applicability in other sciences, it has grown so much and also growing rapidly that today it can be treated as a separate branch of Mathematics in its own right.

All these days, anyone who wanted to know what knot theory is always started with the excellent, 1962 survey article 'A quick trip through knot theory' by R. H. Fox or with the book *Introduction to Knot Theory* by Crowell and Fox. However, even these two expositions demanded quite a bit of preparation in algebraic topology and indulgence from the reader. For instance, the knowledge of fundamental group and the presentation of groups was very essential. Not so any more. The present volume by KM is a proof that anybody can acquire a decent knowledge of a lot of useful knot theory without much expertise in algebraic topology. Today, if somebody approached me for some elementary knowledge of knot theory, I can place KM's book in her/his hands without any hesitation.

Mathematically speaking a knot is merely a smooth embedding of a circle in the 3-dimensional Euclidean space. One can project the entire knot onto a plane to obtain a smooth curve with only finitely many points of overlaps. We can also arrange this projection in such a way that at each of these overlaps, only two of the strands meet and they are perpendicular to each other. By making a small cut while drawing one of the two strands at the meeting point, we indicate which one lies underneath the other. Such a projected plane figure is called a regular knot projection.

The entire knot theory can be carried out from studying such a regular knot projection. Thus, many ideas and concepts about knot theory can be understood by merely drawing appropriate plane figure. Since we are not interested in the actual length of the knot etc., it is fairly obvious that we can introduce a number of operations on the knot which alter it considerably and yet treat it as 'equivalent' to the given knot. These operations are called elementary knot moves.

How far one can go on like this? KM could come up with a whole neat volume written in this style without much technicalities. He declares his intentions of keeping the book totally devoid of all clumsy technicalities and he has succeeded in it. The equivalence of knots, sums of knots and prime knots, knot-cobordism and slice knots, what it means to construct knot tables, and the fundamental problems of knot and link theory are explained in the first three chapters. The classical knot invariants such as the minimum number of crossings, the bridge number, unknotting number, the linking number, colouring number, etc. occupy the next chapter. It all looks so soft so far. However, already, the author points out many open problems which have defied solutions for all these days.

In chapter 5, the theory comes to one of the major turning points in its history. The Alexander polynomial has played a very important role in the classification of knots. Classically, one introduces this concept via the so-called free differential calculus of the presentation of the knot-group or through covering spaces. This approach is quite technical and not surprisingly, KM avoids it and introduces the Alexander polynomial through the Seifert matrix. Thus chapters five and six deal with Seifert surfaces, s-equivalence and Alexander–Conway polynomial, signature of a knot and its usefulness in detecting chirality of knots. The author does not forget to point out the efficiency of Conway's method in making the Alexander polynomial more computer-friendly. It is remarked that this is a case of technology catching up with the mathematical theory.

Chapter 7 contains a satisfactory classification of those knots which can be drawn on the surface of a standard torus.

In chapter 9, the author comes up with another important step in the development of knot theory, again due to Conway, viz. the theory of tangles. The next logical step is the study of braids and the relation with the knots and links. An important theoretical result here is Markov's theorem. It says how two different braids arising from the same knot are related, viz. by the so-called M-equivalence.

We are naturally led towards the great revolution – the Jones Polynomial, serendipitously discovered by V. F. Jones in 1984. An important aspect of the Jones polynomial and its subsequent offshoots is in the fact that they have unlocked connection of knot theory with various applicable disciplines. Of course, it is not necessary to go through the same route as Jones took via the study of operator algebras to understand Jones polynomial. One has to merely axiomatize the skein relations and that is what is done in chapter 11. After discussing the basic properties of the Jones polynomial, KM already includes open problems. For example, it is not known whether there exists any non trivial knot with its Jones polynomial equal to 1. The chapter includes discussion of some of the other offshoots such as the HOMFLY polynomial, the Kauffman's polynomial, etc. It concludes with proofs of three of Tait's conjectures about alternating knots.

The next three chapters treat relation of knot theory in three applicable disciplines – the statistical mechanics, molecular biology and chemistry. These chapters are useful to people working in either areas.

The last chapter treats the most modern concept in knot theory – Vasileiv invariants. Indeed, these invariants are assigned to even a wider class of objects, viz. singular knots and as such they are more powerful than all the invariants considered so far. However, it is not known whether Vassileiv invariants form a complete set of invariants for a knot. Examples of knots not distinguishable by any given finite set of Vassileiv invariants are included.

The book contains two tables, one giving knots up to eight crossings and the other containing Alexander and Jones polynomials for these knots. Notes containing eighteen footnotes is included. As the author points out the bibliography is strictly for the work referred in the body of the book, other references on the subject can be obtained from these sources in turn.

It goes without saying that, one could

not have given proofs of many results, with such a self-imposed restriction of avoiding technical details. Nevertheless, the author has done a very good job, the only exception being chapter 8, in which the author attempts to outline aspects which are more topological in nature such as the Dehn's surgery, branched coverings, etc. A typical exercise in this chapter asks the reader to show that the torus is not a covering space of a 2-dimensional sphere. One fails to understand the kind of audience the author may have in mind, in including such exercises immediately after giving the definition of a covering space. The book can do well without these eighteen pages. This book is translation of the original Japanese version. Even though I do not know Japanese, I feel that there is a lot of scope for an improvement in the translation.

Although this book may not impart any lasting education in knot theory to the reader, it will not fail to inspire and inform substantially. With so many results in one single place, it may be used as a good reference book also.

Lysozymes: Model Enzymes in Biochemistry and Biology. P. Jolles, ed. Birkhäuser Verlag, Basel, Switzerland. 1996. 449 pages.

Fleming's discovery of lysozyme preceded his discovery of penicillin and both are part of scientific folklore. It was in 1922 that Alexander Fleming reported his discovery of lysozyme in the nasal mucous to the Royal Society. However, when the word lysozyme is currently used, it generally means the enzyme from hen egg white (HEW). Pierre Jolles, who sequenced the HEW enzyme in the early sixties, has been working with lysozymes from various sources and has now put together this comprehensive book on this enzymatic activity.

Lysozyme is widespread in nature. By definition, lysozyme activity consists of hydrolysis of a ß-glycosidic bond between the C-1 of *N*-acetylmuramic acid and the C-4 of *N*- acetylglucosamine of the bacterial peptidoglycan. Analysis of known 75 complete and 13 partial amino acid sequences shows that there are 20 invariant residues. In addition to conventional lysozyme (called lysozyme c for chicken type or conventional type), other distinct types of lysozymes also occur. Lysozyme g (after the Embden goose, the specie in whose egg white it was first discovered) is also widespread, though in bird egg white only. Some lysozyme c, notably from pigeon egg and horse milk have few aspartic acid residues critically positioned, enabling them to bind calcium and are called calcium-binding lysozyme c. The two lysozyme c families along with α-lactalbumin form a lysozyme c superfamily. Evolutionary analysis points to a common ancestor and places the divergence event prior to 400 million years. The question whether lysozyme g also shares the common ancestor is still debatable. However, v-type lysozymes (viral type from phage infecting both gram-positive and gram-negative bacteria), on the basis of similarities between their three-dimensional structures with lysozyme c, are believed to share this remote common ancestor.

Several other phage lysozymes encoded by phages infecting gram-positive bacteria called CH-type lysozyme (first investigated in Chaloropsis) belong to a totally unrelated family. A striking observation which emerges out of these evolutionary studies is that only acid catalysis seems to be essential, the rest of the catalytic process is based upon 'broadly scattered interactions (electrostatic, H-bonding, . . .) and substrate distortions' (p. 58).

The role of lysozyme in bacterial cell wall lysis was elucidated only in 1964. 'An intriguing question, not yet answered, is how the cell controls this dangerous enzyme from premature or unbalanced action. . . although it is clear that they are involved in the metabolism of bacterial cell wall' (p. 63). Equally fascinating is their presence in plants. 'All lysozymes also have chitinase activity but not all plant chitinases are lysozymes. However, for many chitinases, it is not known whether they also possess lysozyme activity' (p. 75). As fungal cell walls contain chitin, it is believed that chitinase activity is used by plants to combat fungal pathogen.

Lysozyme (c-type) is ubiquitous in insects, normally present in blood. In this context, the role of lysozyme as an active defence molecule has been questioned, since in most bacteria, the peptidoglycan layer is not directly accessible to this enzyme. It may be that the main role of the enzyme is in cell wall lysis after the bacterium has been killed.

Both in flies and cows, lysozyme also has a digestive role. Whereas typical lysozymes are basic, ruminant enzymes are neutral and Drosophila midgut lysozymes are even acidic.

Thus this book, consisting of twenty-two chapters, looks at lysozymes from the perspective of protein chemistry, enzymology, protein crystallography, molecular biology, immunology and pharmacological and therapeutic applications. The authors, drawn from various parts of the world, represent a unique wealth of experience.

An attractive feature of this book is that it also captures a sense of history of the growth of ideas. McKenzie's recall of editorial opposition to Campbell's opinion that 'α-lactalbumin may have evolved by gradual modification from lysozyme' is a case in point (p. 365). The lucid discussion on the catalytic mechanism by Karplus and Post nicely illustrates the usefulness of theoretical methods in establishing enzyme mechanism. As few biochemists are familiar with the area of molecular dynamics, the inclusion of this chapter is welcome.

Analysis of formation of disulfide bonds in this enzyme shows that there exists a restricted search of structures and a nucleation in the folding pathway. 'Folding of both denatured and denatured/reduced lysozyme is characterized by transient folding species possessing structural properties of the molten globule state: high content of secondary structure, no tertiary fold and appearance of hydrophobic structures' (p. 144). Imoto has described protein engineering work on c-type lysozyme (p. 163 onwards). Although references to the work on T4 lysozyme by Mathew's group have been provided, a little more extensive discussion on the latter would have been welcome. Also missing is the early chemical modification with the enzyme.

HEW lysozyme was the first enzyme

in which case the three-dimensional structure was available from X-ray crystallography. It is interesting to recall that X-ray crystallography of lysozyme gave the first view of ß-sheet in a globular protein. The X-ray diffraction studies on binding of substrate analogs, transition state mimics and oligosaccharide products to various lysozymes have provided considerable insight into binding of sugars to proteins.

Evolutionary variants of bird lysozyme played a major role in the development of correlation between immunological and sequence differences. 'The anti-hen egg lysozyme monoclonal ab DI.3 is perhaps the best characterized immunoglobulin to date' (p. 303). The chapter by Prager on adaptive evolution of the enzyme focuses on lysozyme c turning into a digestive enzyme and in a subsequent chapter, Irwin discusses this as a link between molecular evolution and evolution at the level of organisms.

The last chapter by Sava outlines the underexploited potential of therapeutic applications of lysozymes. However, a very important warning of general importance is given by Imoto (p. 177), 'Engineered proteins might be sometimes harmful to human bodies; only one amino acid substitution (Ile 55 Thr or Asp 66 His) turned human lysozyme to an amyloid fibril protein'.

In a way, this book also reflects the state of the art in the area of enzymes in general. Pierre Jolles has yet again made a tremendous contribution to biochemistry.

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final version in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred.) A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts, subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.).

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

Haridas Banerjee: A self-taught physicist

Introduction

The Indian Journal of Physics brought out a special felicitation volume, 1996, **A70**, No. 3, on the occasion of the 60th birthday of Professor Haridas Banerjee who retired from the Saha Institute of Nuclear Physics in May 1995, and joined the S.N. Bose National Centre for Basic Sciences as INSA senior scientist. This volume contains an accurate biographical sketch by Samir Mallik, a complete list of the 45 publications of Banerjee and a set of research articles in tribute.

When Ramaseshan requested me to write an article about Haridas Banerjee, the immediate problem was – what could I write that is not already in the felicitation volume? I decided to include his reminiscences told to me which might be of interest to the young student starting out in research. The material opportunities for research are decidedly better today due to the enormous increase in instantaneous communication of research results worldwide. On the other hand, the career opportunities for a research physicist in comparison with other emergent avenues are still such that some dedication to science is involved in making the choice. On balance, the human dimensions of the choice are not very different from what it was 40 years ago.

Why research?

Born on 1 May 1935 at Mymensingh, Bangladesh, Haridas Banerjee faced the choice in 1955 after an M Sc in Applied Mathematics from Calcutta University. Research was not on his list of priorities. He wanted to be an actuary (insurance) and his parents wanted him to be a civil servant (IAS). Things started changing as he came either under the spell or in the proximity of great teachers and scientists which included among others, men like Satyen Bose and Maghnad Saha. But he could not marshall enough courage to take the plunge in research. Research, he thought, could not be done on an empty stomach – one needed adequate financial cushion to get enough time for serious thinking. He had, before him the examples of some of his teachers, who even at a ripe old age were lecturers at Science College earning only Rs 250 p.m. So, in February 1956, when he was given a standing offer of a Senior Research Fellowship at IIT, Khargpur he did not accept it. Instead, he followed the wishes of his parents and started preparing for the competitive examination for IAS. In retrospect, he finds the wishes of his parents quite natural. Theirs was a refugee family uprooted from their homes in East Bengal in 1948. What better security could there be for his parents than having him installed as a Magistrate in some district?

Things changed rapidly in June 1956. First, he discovered that lecturers in IIT, Kharagpur had the same salary scale as that of a beginner IAS bureaucrat. So, he was assured that one need not do research on an 'empty stomach'. Second, his old friend and room-mate in the Hindu Hostel of Presidency College, Sukhomoy Chakraborty, who was doing research in economics at ISI, Calcutta, virtually chastized him. His words were 'What nonsense: why should you care to become a civil servant in independent India?'

Thus, in August 1956 Haridas landed in IIT, Karagpur to claim the Senior Research Fellowship offered six months earlier. For his parents this was a setback, but he was determined.

The challenge

It now appears truly remarkable that Haridas, without any training in theoretical physics was never daunted by the fact that, leave alone quantum field theory, even quantum mechanics was for him a totally unknown territory. He just took the plunge. Perhaps, the shining examples of the illustrious alumni Saha and Bose were still fresh in his mind. The assurance of some of his teachers that he should be quite capable of taking up on his own any new area in theoretical physics, provided the moral support.

Early successes

It took him about a year to teach himself basic quantum mechanics and then quantum field theory. The book *Theory of Photons and Electrons* by Jauch and Rohrlich was just out and he found it extremely helpful. By August 1957 he was ready to embark on research proper. Parity violation in weak interactions had just been discovered and experimentalists were eager to measure the polarization of beta particles. For this they badly needed the formulae for polarized cross-sections for processes involving electrons and positrons. In quick succession of a series of papers Haridas presented the required formulae for Bremsstrahlung, Mott scattering and photo-electric effect. His paper on Bremsstrahlung and that of Christian Fronsdal and H. Uberall of UCLA with identical results appeared simultaneously in *Physical Review*. Ugo Fano and his collaborator sent a paper on polarization effects in photo-electric phenomenon for publication in *Physical Review* without realizing that his paper on the same subject had been published in *Nuovo Cimento* about six months earlier. Their paper finally appeared after Fano incorporated extensive modifications on the basis of feedbacks from Haridas. By the time Haridas submitted his Ph D thesis in June 1959, his papers were well known among workers in the subject, both experimental and theoretical.

Jauch, the examiner of his thesis invited him straightaway to join the Physics Department of Geneva University. Thus, even before he was awarded the Ph D degree in December 1959, he was appointed Chef-de-Travaux in theoretical physics, a tenured position in Geneva University with effect from October, 1960.

The two great influences

During the earliest spell (1960–61) of his stay in Geneva he came in contact with two great physicists Josef Maria Jauch and Leon Van Hove, whose life and work had an abiding influence in shaping his attitude to research. Jauch used to tell him that our works were like our children and we should avoid doing something which might lead to embarrassment. Haridas' first encounter with Van Hove was rather accidental. Accompanied by Jacques Prentki, Van Hove came to his seminar (early 1961) on the Nambu-Jona Lasinio paper on spontaneous breaking of chiral symmetry. At the end of the seminar Van Hove came up to Haridas to offer his congratulations and appreciation. From Van Hove, Haridas imbibed the lesson that in research in theoretical physics, experiments are the elixir of life. A theoretical work is lifeless if it cannot be related to experiments.

Research at home vs research abroad and independence

Haridas never harboured – at least in the early years of his research career – the idea of settling abroad. But before returning to India, he wanted to visit the US. Thus, at the end of the first year at Geneva he told Jauch about his intention to resign. Jauch lamented 'You are leaving me like a hot potato'. Later on when Haridas visited Geneva again in 1969, this time with an one-year assignment at CERN, Jauch told him that had he stayed on in Geneva University, he would have become a Professor there. Haridas went to the US with an assignment at Carnegie Institute of Technology, Pittsburgh in October, 1961 and returned finally to India in October, 1963 to join Delhi University as a Reader in the Physics Department. Half-way during his stay at Carnegie Tech he made a short visit to India to get married to Sunanda, a charming, accomplished woman. From Delhi he moved on to Calcutta in April, 1966 to join Saha Institute of Nuclear Physics where he worked till his retirement in May, 1995.

Apart from socio-cultural alienation, there is something else that dissuaded Haridas from settling abroad. It has been his perception that in important centres like CERN, there is an under current of pressure to follow a set agenda in research. Conformism was at a premium, deviation had a penalty. Haridas however, enjoyed a lay-back style of functioning in research where priorities are set by himself. To quote his student Samir Mallik, Haridas prefers working with others but on problems formulated by himself. Indeed, Haridas is fiercely independent to a fault: he is not a good listener.

Loss of Sunanda and its impact

The loss of his wife Sunanda in March, 1984 was a devastating experience. 'It was as if I lost one leg and to support myself spiritually I had to depend entirely on the remaining leg, my research. My reflexes and attitude were that of an one-legged disabled person, jumping from one challenge to the next in a constant quest of excitement to fill the spiritual vacuum.' He was prepared to take more risks and address challenging and 'controversial' problems. In his own words, 'my children' of this period will continue to be a source of joy and happiness for years to come.

The present

Indeed, Haridas continues to be actively involved just now in the problem of putting fermions on the lattice which, for him, is an entirely new track. As a Fellow of INSA, he takes sincere interest in the activities of INSA and Indian science in general; his particular desire is that more research is done at the Indian Universities. I have known Haridas to be a simple, sincere, serious and hard-working physicist. He is always bubbling with enthusiasm that is infectious and has produced 10 Ph Ds. He is a fiercely independent physicist who has blazed his own track, always treating basic problems which inspire him, independent of what the prevailing fashions are. The canvass of problems on which he worked is truly wide: polarization effects in quantum electrodynamics, dispersion theory sum rules for hadron-scattering, multiparticle production in electron-positron scattering, the U(1) and CP problems in modern gauge theory. Concerning the last cited problem, Fujikawa remarked in the felicitation volume for Haridas Banerjee: 'H. Banerjee and his collaborators continuously clarified the most fundamental aspects of the problem and suggested a careful reassessment of the path integration quantization of modern gauge theory itself.'

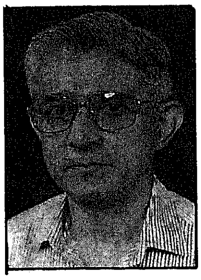
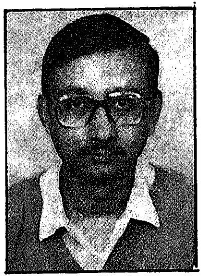
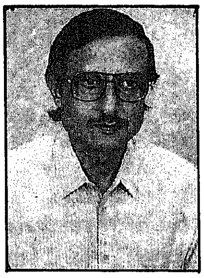
The Indian Academy of Sciences elects new Fellows – 1996



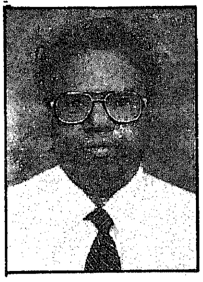
G. V. Anand, Department of Electrical Communication Engineering, Indian Institute of Science, Bangalore
Area: Nonlinear vibrations and waves, ocean acoustics and signal processing.



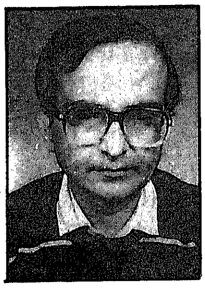
Kankan Bhattacharyya, Department of Physical Chemistry, Indian Association for the Cultivation of Science, Jadavpur, Calcutta
Area: Ultra fast laser spectroscopy and organized assemblies.



Somnath Dasgupta, Department of Geological Sciences, Jadavpur University, Calcutta
Area: Metamorphic petrology, ore geology and precambrian geology.

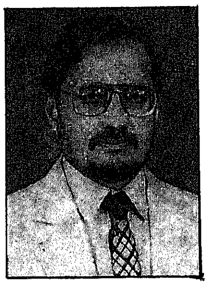


D. Basavaiah, School of Chemistry, University of Hyderabad, Hyderabad
Area: Stereoselective organic synthesis, biotransformations and reaction mechanisms.

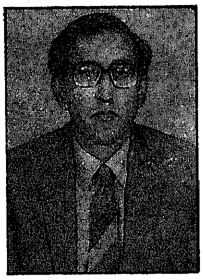


B. K. Chakrabarti, Saha Institute of Nuclear Physics, Calcutta
Area: Statistical physics, condensed matter physics and computational physics.

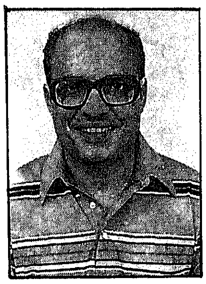
Kasturi Datta, School of Environmental Sciences, Jawaharlal Nehru University, New Delhi
Area: Biochemistry, cellular and molecular biology.



S. V. Bhat, Department of Physics, Indian Institute of Science, Bangalore
Area: Condensed matter physics, solid state nuclear magnetic resonance and electron paramagnetic resonance.

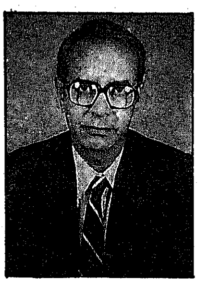


V. S. Chauhan, International Centre for Genetic Engineering & Biotechnology, New Delhi
Area: Peptide synthesis and structure, malaria immunology and vaccine development.



Anil P. Gore, Department of Statistics, University of Poona, Pune
Area: Nonparametric inference and statistical ecology.

A. K. Grover, Solid State Physics Group, Tata Institute of Fundamental Research, Mumbai
Area: Magnetization and superconductivity, NMR applications to solids and vortex state studies in superconductors.

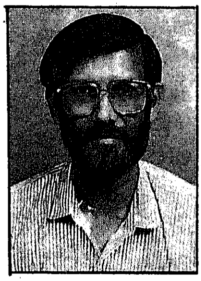


A. K. Mallik, Department of Mechanical Engineering, Indian Institute of Technology, Kanpur
Area: Vibration engineering, kinematics and dynamics of mechanics.

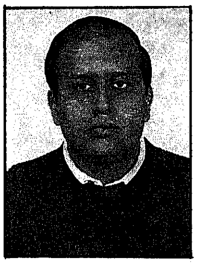
Surendra Prasad, Department of Electrical Engineering, Indian Institute of Technology, New Delhi
Area: Signal processing, communication theory and speech processing.

M. S. Hegde, Solid State and Structural Chemistry Unit, Indian Institute of Science, Bangalore
Area: Electron spectroscopy of molecules and solids, high temperature superconductivity, solid state chemistry and catalysis.

P. C. Pandey, Meteorology and Oceanography Division, Space Applications Centre, Ahmedabad
Area: Satellite meteorology, oceanography and atmospheric sciences.

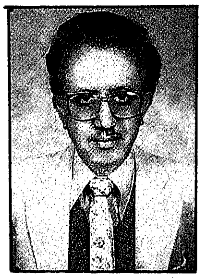


A. Pramesh Rao, National Centre for Radio Astrophysics, Tata Institute of Fundamental Research, Pune
Area: Sun and solar wind, wave propagation in random media, aperture synthesis and radio imaging.

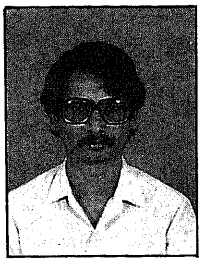


S. Jameel, Virology Group, International Centre for Genetic Engineering & Biotechnology, New Delhi
Area: Molecular biology and molecular virology.

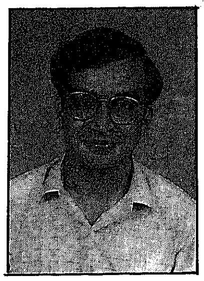
Kapil H. Paranjape, The Institute of Mathematical Sciences, Chennai
Area: Algebraic geometry, topology and differential geometry.



S. Sarkar, Department of Chemistry, Indian Institute of Technology, Kanpur
Area: Inorganic chemistry, bioinorganic enzymology, metal cluster and carbon-cluster chemistry.



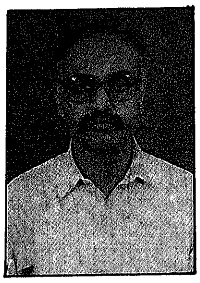
S. Thangavelu, Indian Statistical Institute, Bangalore
Area: Harmonic analysis and partial differential equations.



Jayant B. Udgaonkar, National Centre for Biological Sciences, Tata Institute of Fundamental Research, IISc campus, Bangalore
Area: Physical biochemistry and protein folding.

K. VijayRaghavan, National Centre for Biological Sciences, Tata Institute of Fundamental Research, IISc campus, Bangalore
Area: Developmental biology, genetics and neurogenetics.

Rakesh Tuli, National Botanical Research Institute, Lucknow
Area: Plant and microbial genetics, genetic engineering and molecular biology.



M. Vanninathan, Tata Institute of Fundamental Research, IISc campus, Bangalore
Area: Partial differential equations, numerical analysis, asymptotic analysis and homogenization.

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319–322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

Sister chromatid cohesion during meiosis

Life is tough. To live, cells must not only divide to multiply but must do so correctly, again and again. The 'cell cycle' has been an area of intense recent study. Much of these studies have been done in the yeasts *Saccharomyces cerevisiae* and *Schizosaccharomyces pombe*, in vertebrate cells cultured in the laboratory and in the fruit fly *Drosophila melanogaster*. These studies bear out what is now a cliché worth repeating: The impressive evolutionary conservation of molecular players performing similar cellular functions. These studies on cell cycle and similar studies on the mechanisms of DNA and chromosome replication during the cell cycle have had immense practical relevance to medical problems. After cell division, each daughter cell must receive the correct complement of its DNA, present in the correct manner in each of its several chromosomes. To do this, the mother cell replicates each chromosome and the 'sister chromatids', the replicated chromosomes, 'stick' together to their homologs. At an appropriate time during the cell cycle, the 'sister chromatids' separate and one copy of each chromosome goes to each progeny cell.

The cell cycle can be conveniently divided into four stages. DNA replicates during the S phase and the duplicated chromosomes separate during the M phase. In the cells of our soma, as distinct from germ cells that give rise to egg or sperm, the S and M phases are separated by what are called gap or G phases. The G_1 phase occurs before DNA replication and the G_2 phase before mitosis or cell division. The progress of the cell cycle is subject to controls. There are 'internal' controls or check-points that co-ordinate cell cycle events in space and time and halt progression of the cycle in situations where irregularities occur. These check points will detect, for example, improper chromosome spindle assembly or DNA damage. Another type of control on the cell cycle are 'external controls'. The controls, which can be hormonal, controlled by growth factors or, for example, by neuronal signals; act to determine the extent and time of cell proliferation and have the effect on deciding the time of differentiation, the number of cells that will differentiate and where they will differentiate. In a multicellular organism, therefore, these controls on cell cycle are crucial in deciding the growth and form of an animal or plant. Integrating studies on cell cycle with those on the development of organisms is another exciting area of current research.

Coming back to 'sister chromatid' cohesion and separation, this aspect of the cell cycle has been studied in situations where many of the controls mentioned above fail to operate and in other kinds of situations as well: the timing of cell cycle events, the effect of cellular signaling, the dynamics of chromosome and spindle movement. Proteins involved in each of these events affect sister chromatid separation. During the cell cycle, sister chromatid separation occurs but once, after the S- and G_2 phase where cells have completed DNA replication but have not undergone mitosis. This is during the M phase. If DNA replication continues but sister chromatid separation does not occur, then cells containing many copies of each chromosome, polyploid cells, will be made. For organisms such as humans, this is not a nice thing to happen, but many plants and insects have polyploid nuclei as a normal part of their development. Alternatively, if sister chromatid separation occurs at a higher frequency than DNA replication, then cells with a reduced amount of DNA will result. This is certainly not a very nice thing to happen to a cell. Signals, responses, glues, motors, spindles: in studying the cellular orchestra that these players have organized, we are studying a very fundamental property of life – the ability to replicate and survive to replicate.

Amit Bardhan (**page 376**) addresses the mechanisms underlying the cohesion of sister chromatids during a process different from the relatively simple situations mentioned above. He focuses on meiosis, the events that take place to generate egg or sperm cells in which the chromosome number is half that of somatic cells. In this process too, sister chromatid cohesion and separation are important, critically so since the next generation is involved. Bardhan discusses evidence that suggests that different parts of the chromatids may have different mechanisms of adhesion and reviews the functions of genes that are involved in the process.

K. VijayRaghavan

Potential application of markers

Studies on the organization of genetic material, what it encodes and how it functions in the building of an organism: these are some of the areas that genome analysis addresses. Another major effect of technical advances in molecular genetic methods is the rapidity with which relatively crude maps of genomes can be generated. Given the fact that genomes of 'related' organisms are similarly organized in many respects, even a gross map can be very useful if it can be compared with a dense map in another organism. Thus, the study of how grasses have evolved and diversified has been greatly aided by the study of the genomes of wheat and rice. Similarly, the high level of conservation of genome organization between mouse and human, although they 'separated' about 100 million years ago, allow the functional mapping of human DNA sequences that regulate the activity of genes.

Jayasankar and Dharmalingam (**page 383**) report the first steps of the analysis of the genome of two species of fish. The mapping of characteristics along a linear piece of DNA, the chromosome, requires that the characteristics be identifiable as 'similar but different'. In genome analysis these characteristics are often fragment size and sequence variation at a particular genomic location. Thus, sequence similarity identifies a location and variation in the region can be used to map this location. The polymerase chain reaction (PCR) has been applied widely as a sensitive method for genome analysis studies. Its strength lies in high level of sensitivity of the method, thereby requiring a small amount of sample. This advantage lends itself to applications such as the study of populations in the wild where sample availability is likely to be limiting. The disadvantage of the method is also its sensitivity. Many factors in the reaction can cause small variations that are amplified by the sensitive method. Reproducibility, a key to precise mapping becomes difficult. There are other methods which can overcome this problem and these use sequences called microsatellites. The identification of sequences flanking microsatellites and the use of variability in these sequences between animals is a powerful tool for mapping experiments. Jayasankar and Dharmalingam's experiments are at a very early stage, but the wide use of such methods is bound to allow the rapid genetic analysis of fish. Groups worldwide, particularly in Tubingen in Germany, have made steady progress in the study of the zebrafish, *Danio rerio*. Studies on this model organism will help in the mapping of other fish, in manner similar to what has happened in mouse and human and in plants.

K. VijayRaghavan

Caste and disease

Duchenne muscular dystrophy (DMD) is a muscle degenerative disorder afflicting almost 1 in every 3500 males. This genetic disorder is linked to the Xchromosome and is transmitted from mother to son in a recessive manner. Individuals affected by DMD do not survive beyond their late teens. In the related disease, Becker muscular dystrophy (BMD) patients struggle along until middle age, with a life span of about 40–50 years. Genetic disorders are often amplified by selective breeding amongst restricted populations. DMD occurs at a significantly higher level in Indian migrants in UK as compared to other local and ethnic groups. The disease itself is primarily a consequence of deletions in the dystrophin gene, although the precise molecular mechanisms involving the protein dystrophin remain unclear.

The identification of the gene responsible for DMD and its localization on the X-chromosome, together with polymerase chain reaction methodology, now permit analysis of the population-based variations in the incidence and pattern of gene mutations. Mishra *et al.* (**page 395**) analyse the occurrence of DMD/BMD in different caste groups in Uttar Pradesh. They demonstrate a higher prevalence of the disease in *Brahmins* and *Vaishyas*, presumably a reflection of centuries of strictly caste-based marriages. Their results, however, raise questions regarding a prevailing hypothesis that 'deletional mutations changing the translational reading frame of dystrophin should cause the severe form of the disease (DMD), but deletions still maintaining the frame, result in the milder form (BMD)'.

The ready analysis of the gene responsible for DMD/BMD offers the possibility for genetic counselling. The fact that DMD/BMD is an X-linked recessive disorder, ensures that mothers act as carriers and sons have a high chance (50%) of being afflicted. In a social mileu that places a high premium on the male child, the problems of counsellors are obvious.

CORRESPONDENCE

Plutonium and thorium in the Indian nuclear programme

The paper by R. Chidambaram and C. Ganguly (*Curr. Sci.*, 1996, **10**, 21–35) discusses many aspects of plutonium and thorium utilization in the Indian Nuclear Programme. However, use of thorium is not viable due to some important physics aspects of thorium which were overlooked in the above paper.

1. It is well known that thorium is found in nature without any fissionable isotope. What is not emphasized is that its thermal absorption cross-section is three times that of ^{238}U. This implies that replacing uranium fuel by thorium fuel, in an uranium-fuelled reactor, would require three times enrichment of thorium (^{235}U, Pu or ^{233}U) compared to that of uranium, if nuclear characteristics of the reactor (e.g. burn-up in MWD/Te) are to be maintained. For example, a natural uranium heavy water reactor (PHWR) which uses 0.7% ^{235}U enrichment, would require 2.1% enrichment if thorium is used. Similarly, light water reactors (LWRs) which use about 3–4% enriched uranium would require 9–12% fissile material enrichment when thorium is used. Let us further quantify this statement. A 500 MWe PHWR, now being built at Tarapur site, uses 80 Te of incore inventory of natural uranium which contains 560 kg of ^{235}U. However, if it is fuelled by thorium, it would require about 1.7 Te of pure fissile material in the form of ^{235}U, Pu or ^{233}U. Not only that, a thorium fuelled reactor will also require equivalent out of core inventory of fissile material which would be always locked up in the reprocessing and fuel fabrication plants. Hence a thorium fuelled 500 MWe PHWR would require about 3.4 Te of pure fissile material to have the same fuelling characteristics as those of a natural uranium fuelled reactor.

   India has 78,000 Te of natural uranium according to the paper mentioned above. To burn even fifty percent of it, centuries would be required. If fissile material becomes available as freely as the paper mentions, then natural and depleted uranium would also be available without restriction. In that case there would be no incentive to utilize thorium. Hence, so long as uranium (natural or depleted) is available, thorium would never be used, even if fissile material becomes available without any restriction.

2. Apart from the above nuclear characteristics, two other nuclear properties require attention.

   a) Resonance absorption cross-section of thorium is much less than that of ^{238}U. It is because of resonance absorption of ^{238}U, natural uranium heavy water reactors use fuel channels separated from one another with large quantities of heavy water to slow down fission neutrons past resonances. As thorium would always require enrichment and does not suffer from resonance absorption like ^{238}U, pressure tube type heavy water reactors (with on-load fuelling) do not give any advantage to thorium utilization. If ever thorium is used, it would be used in light water reactors, where clustering of fuel rods and on-load fuelling is not done.

   b) ^{233}U is formed from absorption of neutron in thorium by an intermediate step which involves ^{233}Pa with half-life of 27.4 days. This necessitates removal of ^{233}Pa outside the reactor core for decay or to have a reactor of very low neutron flux (low specific power), as absorption of a neutron in ^{233}Pa is a double loss, loss of a ^{233}U atom as well as that of a neutron. If maximum possible production of ^{233}U is a requirement, then lowering flux in the reactor increases the capital cost of a project. Removal of ^{233}Pa actually means that fuel be removed continuously from the core for ^{233}Pa to decay. Such a possibility exists only with fluid fuelled reactors where the fuel is either in aqueous solution or in form of a molten salt. Several experiments on these concepts were done at the ORNL, USA without much success.

3. The paper mentions that thorium could be utilized in India through PHWRs using natural uranium, Pu–Th and finally ^{233}U–Th route. What does it mean? A 500 MWe PHWR uses 2200 Te of natural uranium in its 30-year life and produces 5.5 Te of fissile plutonium (70% load factor). Extending this fuel cycle to

10,000 MWe programme means utilization of 44,000 Te of uranium, which may be the maximum available for economic exploitation. One also ends up with only 110 Te of fissile plutonium.

This fissile plutonium could possibly be used to enrich thorium to produce ^{233}U. However, it should be noted that yield of ^{233}U is less than half the quantity of plutonium by weight, due to lower neutron production capacity of plutonium defined by its 'eta' in thermal energy range. It would take about 30 years for conversion of plutonium to ^{233}U by successive recycling. The end result would be maximum 55 Te of ^{233}U. As we have seen that a thorium–^{233}U PHWR of 500 MWe capacity would require 3.4 Te of ^{233}U, one would then be able to install about 8000 MWe under this fuel cycle scheme. Canadian studies have shown that it is not possible to design a self-sustaining thorium – ^{233}U based PHWR. Moreover, even for the sake of argument, if one assumes it is possible to design such a system, the end result of all these efforts would be 8000 MWe installed capacity, about half a century from now, provided 10,000 MWe PHWR programme based on natural uranium succeeds with very expensive fuel cycle costs due to low burn up of fuel and other properties of ^{232}U which is produced with ^{233}U and gives strong radioactivity. Are our efforts worth spending in that direction?

4. In case fast breeder programme already taken up in India succeeds, then there would be no incentive to use thorium as it brings down its very property, which is breeding. Fast reactors are Pu–U systems and would never be used for thorium utilization, till uranium is available.
5. In case unlimited availability of fissile material becomes possible due to success of accelerator breeding or dismantling of nuclear weapons, as the paper hopes, thorium may be utilized to use its good metallurgical property. In this case one would use once-through fuel cycle. Highly enriched thorium fuel would be irradiated to very large burn-ups of the order of 100,000 MWD/Te, and then disposed off without reprocessing. This could be done only in LWR reactors.

B. P. Rastogi

Govandi Station Road,
Mumbai 400 088, India

Balakrishnan and Kakodkar reply:

1. It is precisely because thorium appears in nature without any fissile isotope that the first generation of nuclear reactors are all uranium-based, and not thorium-based. The thermal absorption cross-section of thorium is indeed higher than that of ^{238}U, but it does not mean that the initial fissile content that is needed with thorium is proportionately higher. Two facets of thorium fuel cycle that Rastogi has not touched are: a) the much higher reactivity worth of ^{233}U in thermal reactors, compared to that of ^{235}U, owing to the higher number of fission neutrons released per neutron absorbed by ^{233}U; and b) the substantially slower fall in reactivity as fuel burns in a reactor which contains thorium in place of ^{238}U. The initial fissile content in a reactor is not just to make the reactor critical but also to sustain a certain high level of discharge burnup of the fuel. Due to the much slower fall in reactivity with fuel burnup in a thorium-fuelled reactor, the initial enrichment needed in a thorium-fuelled reactor is not three times that needed with ^{238}U but lower. A much better basis of comparison would be life time fissile material requirements. Thorium-fuelled reactors permit much larger use of *in situ* bred fissile material. It has been shown by calculations that at high burnups, life time fissile natural requirements are in fact lower with thorium than with ^{238}U.

   What we should not lose sight of is the fact that we are endowed with a large thorium resource. In energy terms this resource is several times larger than any other indigenously available energy resource that is suitable for bulk electricity production. Several studies showing superior performance of thorium in a number of reactor systems are available and there is no doubt on this score. What is really needed is to develop the specific technologies suitable for thorium exploitation. This is where India will have to take initiative as no other country capable in nuclear technology has any urgency to do so because they have access to large uranium resources.

   It should also be clear that breeders (based on fission or non-fission route) are necessary for growth in nuclear power capacity in our country regardless of whether we are talking of use of uranium or thorium. (In fact we are talking of making use of both.) There is no clash between breeder development and developments in the area of thorium utilization. The sooner we do both, the better off we would be, in view of our large electricity needs.
2. a) While heterogeneity by way of making the fuel in the form of rods as used in both PHWRs and LWRs does give advantage in light of the resonance absorption phenomenon, having the bulk of the heavy water separated as moderator from the coolant heavy water in a PHWR when there is no such separation in a Light Water Reactor is due to the difference in the neutron moderation characteristics of light water and heavy water. It has nothing to do with resonance absorption or with the differences in the nuclear properties of ^{232}Th and those of ^{238}U. Thorium is known to work well in a number of reactor systems and calculations have shown several advantages with heavy water lattice arising out of better neutron economy.

   b) It is well recognized that removing the intermediate product ^{233}Pa from the active reactor core in order to increase its chance of decaying to ^{233}U rather than getting converted to ^{234}U is desirable and that realization is what led to the development of Molten Salt Breeder Reactor in the US and to the fluid fuelled heavy water reactor under the KEMA project in the Netherlands. In the present situation where these technologies did not mature due to other technological hurdles, the PHWR, the heavy water reactor system is much better suited to thorium fuel than the Light Water Reactor with its poor neutron economy and without any capability for on-load fuel reshuffling.

3. The concept of a PHWR started with natural uranium, gradually leading to a self-sustaining ^{233}U + thorium cycle by passing through a plutonium–thorium intermediate stage is nothing new. Our studies have shown that such a self-sustaining fuel cycle started with no external supply of fissile material will increase the PHWR-based nuclear capacity by about 50% compared to what can be achieved with the same quantity of natural uranium used in the once-through mode. What is more important to recognize is that the energy that one can extract by going into Th–^{233}U mode in PHWR is many times larger than without it. One should not confuse the question of growth with energy potential. For growth we need to breed fissile material fast. For realizing the energy potential of nuclear resources, we need to develop thorium utilization capability. We need to do both. When talking about thorium we are concerned with the latter.
4. It is clear that early generation fast reactors should use ^{239}Pu–^{238}U fuel system to enable faster growth of fissile material. That does not preclude beginning with thorium utilization which is equally well done in thermal reactors with perhaps much lower cost.
5. With the hypothetical situation of unlimited availability of fissile material, the question of whether one should opt for reprocessing the discharged fuel or go for a high burnup once-through cycle depends on many considerations. However, as far as comparison between PHWR and LWR is concerned, what can be said with absolutely no uncertainty is that a thorium fuel cycle is far more beneficial in a PHWR than in a LWR for the simple reason that all the neutrons that are absorbed by hydrogen and by the various reactivity regulating materials in a Light Water Reactor with its shut down refuelling will be profitably absorbed by ^{232}Th to produce ^{233}U in a PHWR where the deuterium that is present, instead of its lighter isotope hydrogen, does not absorb neutrons. Besides, in a PHWR with its on-load fuelling there is hardly any excess reactivity that is nullified by neutron absorbing poisons.

Further, from a long term perspective, the recycle option which we are adopting is environmentally far more benign as compared to the option of permanent disposal of fuel.

Thus, in summary, we have to reiterate that thorium has a very important role to play in the Indian nuclear power programme, and as far as its use in thermal reactors is concerned, there is no doubt that thorium is better used in heavy water reactors than in the light water reactors. Even if the high pressure coolant heavy water is replaced by light water due to other considerations, heavy water is certainly the better moderator that can give higher mileage out of thorium – not light water.

ISRO spy scandal – An unending witchhunt

As individuals associated with the country's space programme over the last twenty years and more, we are deeply concerned about what has happened and is continuing to happen to one of our fellow scientists S. Nambinarayanan. We are choosing this route to express our concern because of our inability to intervene meaningfully in the complicated chessboard of moves and countermoves that seem to make inevitable the continued persecution and traumatization of a valued colleague.

Many of us have known 'Nambi' for over twenty years. He was the leader of the team of engineers sent to France for acquisition of liquid rocket technology. He led with great ability, ISRO teams vested with the responsibility of delivering the second and fourth stages of the PSLV project. He was also for a while the leader of the cryogenic engine project. Like all of us, 'Nambi' may have his share of virtues and faults, but we have always appreciated his deep commitment to technology development in the interests of ISRO and the nation. The arrest and interrogation of Nambi in the so-called ISRO espionage case and the attendant newspaper publicity have done immense damage to his morale and even more damage to his innocent family.

The CBI investigation completely absolving S. Nambinarayanan of any wrong doing and the verdict of the Chief Judicial Magistrate, Ernakulam discharging all the accused in the ISRO 'espionage case' are now on record. However the clearance recently accorded by the Kerala High Court to further investigate the case will drag Nambinarayanan and his family through another period of misery. From the record and the evidence behind the 'espionage case', there appears to be no basis for the continued harassment of a person whose innocence has been proven. The reasons for our statement are summarized below.

The major allegation against Nambinarayanan was that drawings and documents relating to the Viking engine and cryogenic technology were handed over to foreign/enemy countries in exchange for large amounts of money in US dollars, and that these took place at three different locations (Madras, Bangalore, Trivandrum) in January, June and September 1994 on specified dates and times.

The detailed investigation by the CBI established:

- that the alleged meetings between the various accused never took place, and the various accused were present elsewhere on the specified dates and times;
- that no documents were handed over;
- that no documents were seized from anyone;
- that an independent ISRO investigation also revealed that in the case of both the cryogenic and the Viking engines, no original drawings or documents of any significance were lost or were missing;
- that no documents of any kind or computer compatible tapes of any kind were shipped out of Trivandrum;
- that no money transactions took place.

The CBI investigations also reveal:

- that Nambinarayanan never met Ramon Srivastava, S. K. Sharma or the two Maldivian women;
- that accusations against Nambinarayanan regarding financial gains from espionage are baseless and as a matter of fact, his life style is very close to that of a poor person;
- that a lie detector (polygraph) test administered to Nambinarayanan by the CBI validates that he was speaking the truth.

There is therefore no evidence to prove that espionage ever took place or that documents or money exchanged hands or that the accused including S. Nambinarayanan benefited financially from these dealings. *In view of the evidence on record, oral as well as documentary, it seems clear that the allegations of espionage have been found to be false, and that the espionage story, both in its genesis and subsequent development had no basis in reality.*

As people who have been associated with technology development in India, we have not been able to understand the logic of what is supposed to have happened in the 'espionage case'. Clearly the acquisition of technology by any foreign power is quite a complex process. Experience indicates that even when drawings are acquired under open technology transfer agreements, their transformation into working hardware takes time, expertise and large financial outlays. The Maldivian women involved, their mode of entry into India or their activities, seem to be inconsistent with the aim of acquiring sensitive technology by any interested foreign power. ISRO does not classify working level documents as secret, top secret or confidential. An internal investigation carried out by ISRO has shown that there are no original drawings related to the Viking or cryogenic engines missing. In fact, in this case, even fabrication drawings, which ISRO routinely passes on to industry, are not missing.

In order to make out an offense under Section 3 of the Official Secrets Act of 1923, there must be sufficient evidence on record to show that any person acts in a manner prejudicial to the safety or interest of the state. Subsection 1 of Section 3 goes on to elaborate what these 'acts' are. We presume that the alleged offense involves:

- approaching, inspecting, passing by or being in the vicinity of a prohibited place;
- making sketches, plans, models or notes which might help the enemy directly or indirectly;
- obtaining, collecting, recording, publishing or communicating to any other person any secret code, password, sketch, plan, model, article, note or other documents or information that is of direct or indirect use to the enemy or which relates to the matter the disclosure of which is likely to affect the sovereignty and integrity of India, the security of the state or friendly relations with foreign countries.

The conclusions of the CBI investigation mentioned above have shown no evidence of any such acts. Indeed searches made by both the Kerala Police and the CBI have revealed no incriminating material or receipt of money from or by Nambinarayanan.

It is clear, that in this case, in view of the facts and circumstances and the legal position, no offence has been committed under the Official Secrets Act by Nambinarayanan.

Like many large organizations, the space organization tends to suffer from petty jealousies and professional rivalries that get translated into personal animosities. These 'internal' problems have so far not spilled over into national scandals involving personal lives and reputations. The 'espionage case' reveals that the country's space programme, or for that matter other strategic programmes, may no longer be immune to outside interference. These dangerous trends, if allowed to continue, can demotivate and demoralize the many hardworking and dedicated professionals who have made Indian achievements in these areas possible, usually for paltry compensations. Such actions are likely to derail these programmes and adversely affect the national interest more severely than any foreign hand.

The espionage case has now been going on for more than two years. The personal life of an important contributor to the space effort like Nambinarayanan has been given a rude jolt if not ruined. His family has been victimized and socially ostracized. Clearly he has suffered greatly and it is time that this 'charade' is brought to an end so that a hapless victim of the so-called espionage scandal can get on with what is left of his life and career. We trust and hope that good sense will prevail and that further harassment of a valued scientist will cease.

Indian scientists win top UN awards

In a forthright editorial 'An uncertain future' (*Curr. Sci.*, 1997, **72**, 5), P. Balaram has painted a realistic scenario of Indian S & T. Even S. K. Joshi in his presidential address of the 1997 session of the Indian Science Congress in Delhi minced no words, when he said in the presence of the Prime Minister that reduction in R&D funding (in India) is a short-sighted policy and would weaken us devastatingly in the long run.

Against this backdrop, a unique hat-trick of global glory comes as a pleasant surprise. More importantly, these international recognitions are considered as good as Nobel prizes.

Specifically, UNEP's Sasakawa Environment Prize for 1996 of US $ 200,000 has been awarded to T. N. Khoshoo of the New Delhi-based Tata Energy Research Institute, for his outstanding contributions to the protection and management of the environment. For over three decades, Khoshoo has been an advocate of strong regional environmental planning for long-term ecological and economic security, particularly in the developing country context (*Our Planet*, 1997, **8**, 33).

The prestigious World Food Prize for 1996, also of US $ 200,000, has been awarded to G. S. Khush of the International Rice Research Institute, Manila, Philippines. World's premier rice breeder, Khush has spearheaded the Institute's programme for developing high yielding, disease and insect resistant varieties of rice. More than 300 improved varieties of rice have been selected and released by national rice improvement programmes from the material developed under the leadership of Khush over the last 29 years. These varieties and their progenies are now planted in about 50% of the world's rice area.

Eminent theoretical astrophysicist J. V. Narlikar, Director of the Inter-University Centre for Astronomy and Astrophysics, Pune, and Jiri Grygar of the Academy of Science, Prague, Czech Republic share the UNESCO's Kalinga Prize for popularization of science. Each year since 1951, UNESCO has conferred the £ 1,000 Kalinga Prize on an individual who had a distinguished career as a writer, editor, lecturer, radio/television programme director or film producer, and has interpreted science, research and technology to the public (*Curr. Sci.*, 1994, **66**, 618–620).

All said, these success stories of Indian scientists strongly suggest that given the right support, both financial and otherwise, we can do wonders. As India's first Prime Minister Jawaharlal Nehru has rightly said, 'It is science alone that can solve the problem of hunger and poverty... The future belongs to science and to those who make friends with science....' It is high time that the government doubled our R & D expenditure to mark the Golden Jubilee of Independence (1947–1997).

Delhi 110 092, India

On the recent editorials

P. Balaram in an editorial (*Curr. Sci*, 1997, **72**, 5) has rightly drawn attention to the declining funding and support for science and higher education in the era of liberalization. Though most of the arguments are balanced and reasonable, the reference to 'herbal petrol fiasco' is made rather naively. It was the immature and unscientific approach adopted by premier science establishments like DST and CSIR which primarily led to the public madness (see, for example, V. Ramamurthy's interview reported in *Nature*, 1996, **383**, 112). Readers may find it amusing to read a guest comment by M. Shermer (*Am. J. Phys.*, 1996, **64**, 1229–1230) the title of which conveys the essential point 'Hope springs eternal – Why people believe weird things' in the context of public perception of science.

I think the title of Balaram's editorial 'An uncertain future' and implied implications could be viewed differently: Is not an uncertain future challenging, worth enjoying, and full of new possibilities? Perhaps *Current Science* can make a virtue of this uncertain future by vigorously promoting informed debate and criticism of science establishment, and disseminating policy matters to the readership. It is worth cautioning against the pitfalls involved in the proposed thrust outlined in the editorial entitled 'Reaching out to industry' (*Curr. Sci.*, 1997, **72**, 97). One must be clear and careful regarding one's role: Why should a scientist be supposed to assume the mantle of an entrepreneur or a graduate physics syllabus be flooded with computer and electronics courses or an engineering graduate seek MBA? Journals like *Journal of Scientific and Industrial Research* ought to focus on 'developing a new synergism between academic science and technological innovation', and journals established for such specific purposes ought to be strengthened. Regarding industry–academia interaction, more than what is already within the scope of *Current Science* would be inappropriate and a short-sighted approach. Depending on the need and urgency, it would be advisable to launch supplement to *Current Science* specifically for industry.

Hello Dolly!

K. P. Gopinathan

The recent creation of a true clone of a mammalian species in the laboratory, a sheep named Dolly, has evoked widespread interest and concern in all sections of people. The major question is how close are we now to generating human clones (see cover).

Hello Dolly, Well Hello Dolly,
It's so nice to have you back where you belong....
You are looking swell, Dolly, I can tell Dolly....

So goes the popular song from one of the greatest hits of Broadway, *Hello Dolly* of the 1960s. We say Hello now to another Dolly but this time near Edinburgh, Scotland. She has become the Darling of so many people already. Created by Ian Wilmut and his team of scientists at the Roslin Institute for Agricultural Sciences, Dolly is probably the first true clone of a mammal. The scientific team has developed a live sheep, now about 6 months of age, from a single cell derived from the udder tissue of a mother sheep by transplanting its nucleus into an egg cell from which its own original nucleus was eliminated. The egg cell containing the nucleus from the fully differentiated udder cell was then implanted into the reproductive tract of a foster mother, which developed to the normal baby sheep. The research paper published in *Nature* by Wilmut and coworkers[1] has raised many an eyebrow.

This indeed is a marvellous technical feat and an exciting piece of science but the hornet's nest has been opened. For, the major concern is – how far away are we from cloning of the human being? A Harvard University Professor is supposed to have written to *Nature* to stop the publication of this article, being genuinely concerned about its social and ethical repurcussions on our race. The US President Bill Clinton has already asked the 'Bioethics Advisory Commission' to review the implications on human beings and has banned federally-funded human cloning research, if any, till clearance is received. The French Government spokesman too has reacted in a similar way. The Pope and the Vatican also have expressed concern on the ethics of man interfering with God's work. Newspapers all over the world have carried stories on this 'development'. So, what is this excitement all about and do we really have to fear? Let us look at the scientific part first.

It is generally accepted that in multicellular organisms, every single cell contains the same set of chromosomes and therefore harbours the same information content. That it is so is established already in plants because from a single cell derived from any part of the fully grown plant a whole plant or tree can be regenerated. This capacity of a single cell to give rise to a whole organism, generally referred to as 'totipotency' was by and large considered to be restricted to the plants. How could a

single cell from a fully differentiated organism derived from, say, the arms or legs of a human possibly give rise to a whole human being? It was widely assumed that such a feat will be impossible although theoretically conceivable. If one completely rips apart the whole human body, the entire set of cells numbering about 10,000 billion (10^{13} cells) should have the same set of chromosomes and genes each one harbouring the complete information to give rise to a whole human being. But how do we know that each cell contained the full complement of the genetic information? No one has sequenced so far the entire set of chromosomes/genes from different cells from a single individual or for that matter even from a single cell of an individual. The evidence is mostly circumstantial and deduced through indirect experimentations. As we know, the whole human body has been formed, after all, from a single egg cell derived from the mother following fertilization by a sperm cell originating from the father. The fertilized egg, the zygote, has gone on dividing to give rise to 2, 4, 8, 16, 32, ... and so on cells, each being the descendent of the immediate parent and consequently inheriting an identical daughter nucleus. In the development process, however, the axes in which the cell divides is an important consideration in the context of differentiation. Thus, the division of the embryonic cell on the X, Y or Z axes, decides the 'head or tail' (anterior/posterior), 'left or right' (proximal/distal) or 'front or back' (dorsal/ventral) development programming of the organism. It is clear therefore, that at precise points of time during the embryonic development, decisions are made about the fate of the cell and all its descendants then obey the order. At a molecular level, does this decision making involve a complete set of rearrangements of genetic information on each of the chromosomes within that cellular nucleus? For certain, we know that in the antibody producing white blood cells, the genome undergoes permanent rearrangements at the immunoglobin locus to give rise to only one particular type of antibody. If such rearrangements have taken place at other loci in other fully differentiated cells, it is possible that one can never retrieve the full genetic information to regenerate the whole animal from a single committed cell.

However, in the amphibians, as early as 1960s the Oxford Zoologist Gurdon[2,3] had demonstrated that if the nucleus derived from the mature intestinal cells of the adult frog is implanted into the enucleated frog eggs, the embryos developed into tadpoles and matured into frogs. But then, a frog is a frog is a frog! The experiment was widely appreciated by the scientists and hardly led to any serious reactions from the general public. In essence, the present set of experiments conducted by Wilmut and coworkers are similar except that the system explored is mammalian. Obviously, we have moved several steps closer to the possibility of doing such experiments with humans and that indeed is the concern. In fact, the developmental potential of mammalian embryonic nuclei (but not those from adult or fully differentiated tissues) was reported previously in the 1980s by Illmensee and colleagues[4] by transplanting them into mouse eggs and obtaining live born nuclear transplant recipients; however this claim has been contested subsequently[5–7].

What are the special features of the Wilmut experiments reported presently? The research team had earlier established that viable lambs can be produced by transplanting nuclei from very early sheep embryos (blastocysts) to enucleated eggs. They now demonstrate that the same procedure can be used to obtain viable lamb from a cell line that was established from the udder (a fully differentiated tissue) of a six-year-old ewe. In the past, the attempts to clone mammals have had mixed outcomes. Nuclei taken from mouse embryos older than 8-cell stage from the totipotent embryonic stem cells or from inner cell mass failed to produce viable embryos, although adult sheep clones were produced using nuclei from early morula (8–16 cell stage embryos). The major problem in getting the transplanted oocytes to develop properly was the cell cycle incompatibility between the donor nucleus and recipient oocytes (see Figure 1, for cell cycle progression). In mammals, most of the embryonic nuclei used as donors were in either the S or G_2 (non-diploid) phases of the cycle, which is not compatible with the diploid metaphase II-arrested oocytes, the preferred recipient stage. Additional rounds of DNA replication and premature chromatin condensation in such cells result in abnormal development. In the present set of experiments, the nuclei from cells that have been arrested in G_0 phase of cell cycle by serum starvation were utilized for transplantation which perhaps provided the most favourable conditions for the proper development of the embryos.

By these experiments, Wilmut and coworkers[1] have clearly established that during the growth and differentiation of an embryo, irreversible modifications of the genome do not occur in somatic cells. Nuclear transplantation from somatic cells could be used to produce clones of sheep that have been selected for particular traits, although the number of successful transplants is still low. This approach may prove to be of great use to produce sheep of desired germ line, though still not easily practicable. Newspaper reports have already appeared stating that at the Oregon Primate Research Center in the US, Don Wolf and his colleagues have established the clones of simians, although by a different approach. Here, instead of nuclear transplantations into the egg cells, the reimplantation of portions of blastocysts derived from a single fertilized egg into surrogate mothers has been successfully attempted to generate the clones. However, the latest newspaper reports state that the technique employed here was also nuclear transplantation. Have we thus moved a step closer to the cloning of the human race or is it still a bug bear? Technically, the feat is not going to be very different but the issue is an ethical one, as to how far we want to go. If one were to clone a particular human being with the 'desired traits', the first task is to address the question of what the desired traits are. Is it fair skin or blue eyes or blond hair, or is it a higher level of intellect that makes a better human being? Are the presence of genes alone enough to confer the behavioural traits of the clone and what role does the environment play to dictate his/her gene functions? The desire to clone the idolized 'father' by an overaffectionate son or daughter, or for that matter, of any other kith or kin, if achievable, should also address the matters related to personal relationships and emotional attachments. In the above instances even if the clone is generated through the successful embryonic development, will the emotional linkage between the individuals be sustained? In other words, can the soul be custom made? Duplications do occur naturally as in the case of identical twins, but the idea of a shadowy duplicate of oneself is undoubtedly a deeply disturbing thought. Are the clones of Frankensteins and Adolf Hitlers already in the production pipeline and if not can the days be far?

Biogenicity of stromatolites and early life on Earth

A. V. Sankaran

The earliest evidence for the origins of life on Earth go back to more than 3.5 billion years (b.y.) and this has been gathered from what is believed to be remnants of life on primitive Earth – certain odd dome-shaped structures called 'stromatolites'. These are actually made up of wavy and wrinkled layers, hardly 50–200 μm thick, and built out of fine marine sedimentary particles of silica, carbonates, barite or gypsum by microorganisms (bacteria, algae) layer upon layer (Figure 1). Earlier this century, these layered structures were mistaken as remains of other organisms like formaminifera, sponges and related marine species. However, their biological connections became established only after finding microbial fossils in some. Further, in modern times, cyanobacteria and algal communities are seen building up stromatolites off the west coast of Australia[1,2], and also in certain hot springs. Scientists were, therefore, convinced about the biogenicity of these primeval structures. Stromatolites have been reported from many parts of the world and some of the well-known occurrences are from Gunflint Formation in Canada (2.0 b.y.), Bulawayan Group in Rhodesia (2.5–2.8 b.y.), Pongola Group in South Africa (3.0 b.y.), Warawoona Group in Australia (3.3 b.y.) and in India they have been described from the Sandur region, Karnataka, dated around 2.9 b.y.

During the last few years, scientists have pushed back the beginnings of early life by reporting discoveries of microbial fossil-bearing stromatolites from the 3.4–3.5 b.y. cherts of Warawoona Group and Pilbara Block in western Australia[3,4], the 3.5 b.y. cherts in South Africa and 3.77 b.y. quartzites from Greenland[5]. Several of globally distributed Banded Iron Formations, some of them as old as 3.5 b.y. are themselves believed to be strong evidence for life, inasmuch as the conversion of iron to iron oxide in these formations requires free O_2 (absent 3.0 b.y. ago) which must have been supplied by O_2-producing microorganisms (cyanobacteria). These, no doubt point to the prolific activities of bacteria in those distant geological times and also imply that terrestrial life must have begun much earlier to have evolved sufficiently to build these organo-sedimentary stromatolites[6].

Though geologists were convinced about the role of microorganisms in building up the stromatolites and hence considered them as good evidence for life on primitive earth, doubts have now arisen whether some of the stromatolites can as well be non-biologic in origin, quite unrelated to life. This view has been particularly strengthened by the absence of fossil microorganisms in many stromatolites of Archaean age (4.5–2.5 b.y.), a view further supported by the latest observations by John P. Grotzinger and Daniel H. Rothman of MIT who found inorganic precipitates of aragonite and calcite on the ocean floor strongly simulating stromatolite structures[7]. The reliability of stromatolite as evidence for life has, therefore, come under a cloud and geologists have now felt a need for reexamination of the notable occurrences around the world as to their mode of genesis.

In their work, which has somewhat jolted the accepted notions, Grotzinger and Rothman have made critical morphological characterization of 1.9 b.y. old sub-tidal reef stromatolites from Wopmay Orogen, northwestern Canada; they examined the out-crops on the field and undertook laboratory measurement of thicknesses of calcite layers on polished samples and felt, on basis of microscopic textures and fractal dimensions, that these layered structures would very well be non-biologic or abiotic. According to the mathematical models they evolved using computer simulations, they could account for the development of these layered growth through the following four abiotic growth mechanisms: '(1) fall-out of suspended sediments; (2) diffusive smoothing of settled sediments (that is, sediments move downhill at a rate proportional to slope) and surface tension effects in chemical precipitation; (3) surface-normal precipitation; and (4) uncorrelated random noise representative of surface heterogeneity and environmental fluctuations'. The two, however, do not doubt the biogenicity of some of the world occurrences of stromatolites, but feel that in the absence of microfossils or other unambiguous clues in them, their biological origins cannot be taken for granted.

Grotzinger and Rothman's proofs about the abiogenicity of some of the stromatolites do not, however, rule out

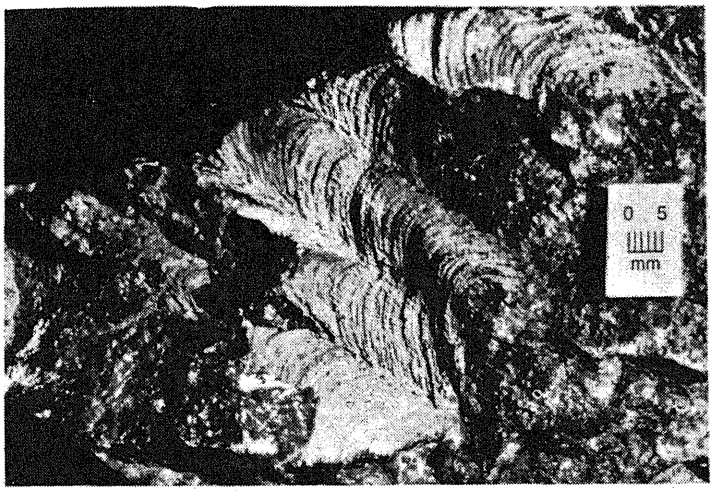

Figure 1. A typical wavy stromatolite from 2.5–2.8 b.y. old Bulawayan Group, Rhodesia, showing the finely-layered structures.

the prospect of determining existence of life during the pre-3 billion year period. Their work only underlines the need to have samples exhibiting undisputed features pointing to their organic links or preserving some typical biogenic signatures, which are neither degraded over time or altered by metamorphism and other geologic processes. A few researchers have been able to find such pointers and have undertaken studies using them to prove unambiguously biological processes at work during the early or primitive times. The studies of carbon residues, believed to have been derived from microfossils from 3.8 b.y. old quartzites from Greenland, is one example of an indirect evidence reported, after Raman microprobe studies on them revealed spectra typical of organic functional groups[5]. However, these findings have not apparently, received acceptance because of the possibility for alternate interpretations of the data. Likewise, scientists were skeptic about similar evidences supporting life processes from studies using sulphur isotope ratios (as evidence of microbial sulphate reduction) on 2.7–3.0 b.y. old samples[8].

In this context, a recent work by Stephen J. Mojzsis of Scripps Institute of Oceanography and his colleagues from California, Australia and UK[9] has come out with a more convincing evidence from 3.8 and 3.85 b.y. samples. They have taken recourse to the isotope ratios of $^{13}C/^{12}C$, as these values in the biologically-derived carbon are distinctly different from those from inorganic processes. Biogenic carbon, i.e. formed by natural decay of organisms, are enriched in the lighter isotope ^{12}C while the inorganically derived carbon have more of the heavier ^{13}C and hence the $^{13}C/^{12}C$ ratio can be used as a reliable indicator of parentage, whether biologic or nonbiologic.

Mojzsis and coworkers have done exactly this and took for isotope measurements 3.8 b.y. old Isua Formation (Banded Iron Formation or BIF) in west Greenland and a slightly older 3.85 b.y. specimen from nearby Akilia Island. They examined the carbon residues present in the form of graphite, unalterably locked up within apatite, a mineral found in these BIF. This mineral, $[Ca_5(PO_4)_3(OH, F)]$ a fluorophosphate of calcium, is a notable constituent of marine sediments where 'organisms participate in concentrating organic phosphate species from solution, and by recycling organic phosphate species from decaying P-rich bioorganic matter'; carbonate hydroxy fluorapatite is nucleated around calcium which these microorganisms can seggregate from water[9]. This microcrystalline apatite eventually gets diagenetically recrystallized to crystalline apatite while the inclusions of carbonaceous material are converted to graphite by later metamorphic event. In an earlier work on whole rock samples from the same area in Greenland, Manfred Schidlowski of Max Planck Institute for Chemistry found ^{13}C to ^{12}C ratio 1 to 1.5% lower than the international standard and ascribed this to origin from organisms[10]; but, others considered the difference too small and the values also, fell within the range usual for inorganically derived carbon. However, the carbon fractions Mojzsis and his colleagues examined were on inclusions from apatite, about 10 μm in size showing some 20 picogram of carbon, unaffected by later geologic activity thus preserving the pristine isotopic ratios. Using intense ion beams from an ion microprobe to penetrate the apatite, the authors extracted carbon ions from these graphite and thereafter determined the proportions of light and heavy carbon isotopes in the extract by mass spectrometry. They found that the ratios in these inclusions were 10 to 15 per cent lighter, well outside the range created by known inorganic processes, and hence 'characteristic of carbon isotopic compositions for organic matter'[9] and a strong evidence for life on earth as early as 3850 million years ago. Though electric discharges can alter carbon isotope ratios in organic material and incoming meteorite falls can contribute to light isotope enhancements, such possibilities are ruled out in Mojsis' samples in view of adequate evidences showing bolide impacts were much subdued by 3.8 b.y. (ref. 12).

Evidences in support of past biotic activity, therefore, must invariably have signatures unaffected by passage of time or later geologic processes. It is in this context that the determination of carbon isotope ratios on inclusions of carbonaceous materials, unequivocally biologic, well preserved within stable mineral structures, assumes importance. With the current availability of highly sophisticated analytical tools to extract and analyse extremely miniscule fractions of samples, sometimes as little as a few atoms, it is hoped that scientists may soon set at rest the ongoing controversies about biogenesis of stromatolites or about life on Mars[11].

Possible involvement of surface ultra-structural features in utilizing the semi-conductive properties of pigments in chemically coloured insect cuticle

The insect integument is characterized by the presence of cuticle, an extracellular matrix. It is constructed of microfibrils made of chitin, which is a high molecular weight polymer composed of *N*-acetyl glycosamine residues, joined together by β-glycosidic linkages, organized within the protein matrix[1].

Insect cuticle may be transparent or coloured, depending upon its function in various locations of the body. The transparency of the cuticle covering the ocelli and compound eyes, for examples, is maintained to allow entry of light through it. The transmission of light through other photosensitive structures, such as the cuticular window over the pupal brain in some silk moths, is also through transparent cuticle. The importance of electron microscopical studies on the surface ultra-structural features of transparent cuticle in relation to their varied and extensive role as interference filter, anti-reflection device, reflector of specific wavelength, etc. has been amply highlighted in the literature[1,2–5].

As far as the coloured cuticle is concerned, it may have either chemical or physical colours. The physical colours of insect cuticle are the result of some optical phenomena such as diffraction, interference, etc. The chemically coloured cuticle on the other hand, is formed by internal infoldings of the cuticle, as in the case of coloured wing and integument of Lepidoptera and Hymenoptera respectively. Pigment granules in these examples (pteridines) are present within or above the epidermal cells. The melanin pigments on the other hand, are embedded inside the cuticle[6].

Although reports on involvement of surface ultra-structural features in various optical phenomena exhibited by transparent[2–5] and physically coloured cuticle[7] exist in literature, the same is not available for the chemically coloured cuticle.

Here, I report the unique surface feature of the yellow spots on the cuticle of a coccinellid, subcoccinella sp. with the help of scanning electron microscopy, which may be relevant to its functional significance. The elytral cuticle of the beetle was secured horizontally to brass-stub (10 mm dia; 10 mm height) and coated with gold in a JFC 1100 (Jeol) ion sputter coater. Observations were made with a Jeol JSM 35 CF scanning electron microscope operated at 15 kV.

The dorsal surface of the yellow spot is characterized by the presence of innumerable spherical bodies (dia = 0.8 µm) arranged in definite pattern (Figure 1). They are separated from one another by a space of about 0.2 µm in certain places, but in most of the parts, they are very close to each other and are intact. At places, the surface of the yellow spot contains some systematically-arranged short processes (spines), which are extensions of the cuticle. The spines are arranged in a circle around the rim of a large spherical body (10 µm in diameter), at a distance of about 15 µm from the small compact spherical bodies. Within the spherical body, there exist some sensilla, about 7 µm long and 0.8 µm broad. The sensilla protrudes from a socket,

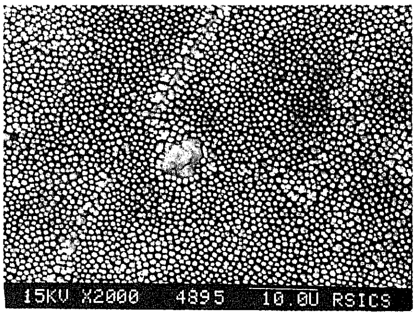

Figure 1. Scanning electron micrograph of the surface feature of the coloured spot (bar = 10 µm).

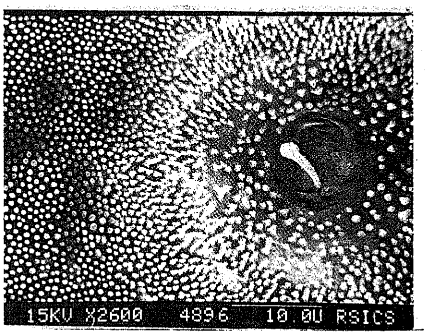

Figure 2. Arrangement of cuticular spines and sensilla (bar = 10 µm).

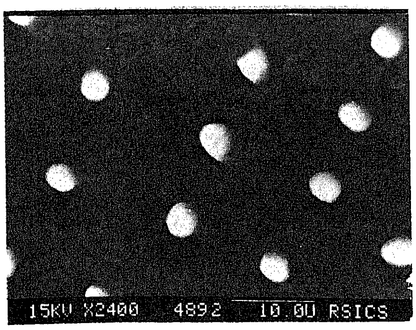

Figure 3. Scanning electron micrograph of the ventral surface of the coloured spot (bar = 10 μm).

about 1.6 μm thick, and tapers towards the tip with a thickness of 0.4 μm (Figure 2). It is interesting to note that the occurrence of intact small spherical bodies and the arrangement of spines and sensilla around a larger sphere is unique for the dorsal surface of the coloured spot. Further, the surface feature of the yellow spot, the location and arrangement of spines and sensilla do not show any individual variation in different specimens of the same species. A similar type of surface feature, however, is not observed on the inner surface of the coloured cuticular spot, which is smooth, but contains some cuticular processes (Figure 3). The general elytral cuticle other than the coloured spots is also smooth.

The spherical bodies on the external surface of the coloured cuticular spot appear to be related to the position and shape of the cells lodging the pigments responsible for the colour of the spot, since it is known that the surface pattern of the epicuticle reflects the outline of epidermal cells[1,8]. In fact, the structural pattern on the cuticular surface corresponds to the position of epidermal cells at the time of outer epicuticle deposition[9].

The intactness of the small spherical bodies on the surface of the coloured cuticular spot, suggests a similar kind of intact nature of the pigment cells in the epidermis. In this context, it can be mentioned that intactness of the tegumental pigment cells in some wasps was reported to be essential for photoconductive activity of the cuticle covering the pigment containing region[6].

Further, it is well known that many pigments such as melanins, carotenoids, haemoglobins and chlorophylls possess properties of organic semi-conductors[10], and are sensitive to changes in temperature and light intensity[11]. In the present case also, it is logical that the pigments associated with the cuticular spots serve as a sensitizer for light and temperature change. Such changes are expected to be transmitted to the nervous system through the sensilla associated with the pigment bodies. The changes in intensity of light and/or temperature are perceived by the sensitizing pigment, which transmits those changes to the cellular elements of the cuticular sensilla and thence to the nervous system.

A point of interest to be noted here is that, for conversion of heat and/or light into electricity, for sensing capacitive pressure, for detecting thermal conductivity and for sensing temperature, the present day electronic technology relies on semiconductor thin film device. The questions that are debatable in this context are, whether or not the semiconductive properties of coloured cuticle in general are utilized by the insects for sensory detection of temperature, light, humidity, pressure, etc. and whether or not they store the electric energy produced in the transduction process.

Lepidontal alterations of the circuli on the scales of freshwater snakehead, *Channa punctatus* (Bloch) upon exposure to malathion

Malathion, an organophosphorous insecticide, has been widely used to combat the attack of insect pests in northern India, without realizing the adverse effects on the aquatic organisms when it enters the waterbodies as run-off. It is a proven fact that it has higher toxicity even at low concentration levels to the aquatic organisms and comparatively lower toxicity to terrestrial mammals.

In the past, various organs have been employed (qualitatively and quantitatively) to assess the toxicity of various toxicants, but the use of scale as pollution indicator is of recent inception[1,2]. The detailed study of marginal circuli and mineral composition[1,2] of various parts of the scale of *Channa punctatus* (Bloch) has been used as an indicator of pollution upon exposure to different concentrations of endosulfan. We confirm here the earlier observations.

were purchased from the local fish market of Chandigarh (76°46'30"E; 30°40'0"N). Fish were acclimatized for 7 days and fed once daily either with minced goat liver or live mosquito fish *Gambusia affinis patruelis* (Baird and Girard) collected from the pond located in the Botanical Garden of the Panjab University, Chandigarh. The LC_{50} value (96 h) of malathion (50% EC) for *Channa punctatus* was found to be 0.62 mg/l (ref. 3). The desired concentrations, i.e. 0.05, 0.10 and 0.25 mg/l of the pesticide in tanks were achieved by adding appropriate quantity of the stock solution. A parallel control group was maintained in toxicant free tap water (pH 6.8; dissolved oxygen 8.91 mg/l and total hardness 84 mg/l). A batch of 8 acclimatized fish was released in each tank of 20 l capacity. After 5, 15 and 30 days exposures, scales overlying the lateral line, leaving 7–8 dorsal fin rays, preferably from the second row were removed. These scales were sonicated for about 15 min to remove the extraneous material. Dried and cleaned scales were mounted on aluminium stubs, sputter coated with gold (100 Å thickness) and studied under vacuum using JEOL, JSM-6100 scanning electron microscope.

The cycloid scale of *Channa punctatus* (Bloch) is semioval in shape (Figure 1 *a*) and consists of three distinct parts, viz. anterior, posterior and lateral. The circuli are widely spaced on lateral sides and bifurcate when they enter the anterior region (Figure 1 *a*). In the posterior side, thick circuli are present. Each circulus in this region is formed by the fusion of 2–4 circuli present on the lateral side. This region also has several vertical rows of chromatophores. In the anterior region several radii, mostly tertiary ones, cut the circuli at a right angle. The SEM studies revealed that the anterior circuli bear rows of minute hook-like structures known as lepidonts (Figure 1 *b*). Lepidonts help the scale to anchor on fish body[1,4]. A lepidont is pointed at its free end and has a broad base. Each lepidont is firmly attached to the circuli (Figure 1 *b*). Initial observations revealed that upon prolonged exposure, one of the effects of toxicant is the loosening of the scale on the fish body as the main function of the lepidonts is to fix the scale on body of fish. The present study is restricted to discussing the toxicological impact of malathion on the lepidonts.

It has been observed that tips of approximately 5% of the lepidonts were broken from the anterior one third portion at 0.05 mg/l of malathion at an exposure of 5 days (Figure 1 *c*). With the increase in the concentration, i.e. 0.10 mg/l for 5 days, about similar percentage of lepidonts showed complete breakage from the base portion too (Figure 1 *d*).

Further increase in exposure period to 15 days at a concentration of 0.25 mg/l level of malathion caused complete damage to the circuli and the entire calcareous material became disorganized (Figure 1 *e*) accompanied by the loosening of the scale on the body, envisaging that the lepidonts play a significant role in anchoring the scale on the body of the fish.

Upon exposure for 5 days and 15 days to lower concentration levels of malathion, lepidonts beckoned less occurrence of breakage but with an increase in exposure duration to the extent of 30 days the frequency of the breakage showed drastic increase. At an exposure of 0.10 mg/l for a prolonged period of 30 days, 40% of lepidonts showed extreme breakage exhibited in various forms. Circuli on which the lepidonts are attached also showed certain level of damage (Figure 1 *f*).

Endosulfan[1,2] appears to be more toxic than malathion as even the lower concentrations of endosulfan damage both the circuli and lepidonts. The mineral composition of the different parts of the scale particularly the calcium also showed variations[2].

The present studies have clearly indicated that the lepidonts on the scale of *Channa punctatus* gave excellent response in the form of varying degree of damage to the varying concentrations of malathion. This damage is related to both, the dose and the exposure period. It is, however, difficult to conclude at this moment which one is more disastrous. Circuli showed less response at lower concentrations of pesticide exposure, but prolonged exposures certainly damage them too. Hence it can be concluded that lepidonts present on the circuli of the scale of *Channa punctatus* can be employed as a reliable pollution indicator with a high degree of exactitude.

GENERAL ARTICLE

Conflict in science policy declarations: An analysis of the Indian model

Pawan Sikka

With a view to establishing a vision in India, policies, strategies and structures for science and technology (S&T) have been evolved, under a planned development approach since 1950. It is now observed that S&T policies, when considered in the overall economic milieu, have interacted with the trade, fiscal, industrial and political-policy instruments of the country. The need for evolving an integrated approach is stressed for making the science policy declarations of India as comprehensive as possible and goal-oriented towards attaining global scientific excellence. Developing countries can benefit from the rich experience of India.

APPRECIATING the role of science and technology towards economic development, policy making and planning exercise is undertaken and legislative measures are enacted for enhancing the country's potential. It may require consolidating and strengthening the input-resources like natural resources, manpower utilization, technological innovations and financial allocation. The need for science policy formulation and implementation is far more important for developing countries, than the developed ones, where the choice is between the planned development of science and no significant development at all.

Developing countries, which are now emerging on the world-scene of science and technology, could derive a benefit from the experience of the Indian model of socio-economic development based on science and technology, where policy measures were undertaken from time to time, during the past almost 50 years[1–6]. While charting the development of science in India, the following paragraphs would indicate areas of conflict in science policy declarations that would require some remedial measures and fine-tuning/adjustment, so as to meet with the global challenges *vis-à-vis* societal advantages.

Science in India

Policies, strategies and structures for S&T have been evolved in India, under a planned development approach since 1950 (ref. 6). The Government's attempts at science policy making in India are directed towards

- making S&T an integral part of all sectors of national activity for achieving self-reliance;
- developing capabilities essential for fulfilment of S&T tasks in these areas;
- undertaking of well-defined S&T missions; and
- provision of fiscal measures[7,8].

The Government of India, with a view to providing avenues for economic development on the scientific basis, adopted a Scientific Policy Resolution (SPR), in 1958, which provided guidance by directing the attention of scientists to some of the critical problems of society for which S&T could provide answers[9]. Besides, a number of policies have been adopted at the sectoral levels, in the recent years, to have an impact on the performance of S&T in the country, e.g. policies for energy, education, electronics and computer, environment, materials, drugs and chemicals, housing, patents and copyright, etc. (Table 1). Thus, the existence of the nature of Acts for the promotion and protection of S&T can be taken as an indication of the national commitment to the development of S&T towards the economic growth of the country[10].

Science policies declarations of the Government of India have played a dual role in order to

- foster and promote research activities in S&T in areas of interest and concern to our scientists, and at the same time to
- ensure that S&T are harnessed to programmes which are geared to fulfilling the needs of society.

Nehru employed the Scientific Policy Resolution of 1958, as Magna Carta for the development of science in India, while the visions of Shanti Swaroop Bhatnagar, Homi Bhabha and Vikram Sarabhai led to the establishment of a chain of national R&D laboratories in the fields of industrial, atomic and space sciences respectively[6]. The Government of India has assumed a major responsibility in supporting several initiatives and aspirations. This has resulted in

- providing enhanced budget for promoting S&T in the

country, viz. Rs 20 crores in 1951–56 to about Rs.15,000 crores in 1992–96;

– creating infrastructure for the R&D establishments;

– establishing scientific, technical and educational institutes for generating the necessary S&T manpower, which now stands third largest in the world[11];

– supporting science in making all efforts so as to accrue all the benefits to the people by the application of S&T in India.

The pattern of development for further utilization of India's S&T resources, in particular, on measures for striking a balance between the domestic capabilities and foreign assistance has been the mandate of the apex science advisory bodies that has been identifying and recommending measures which would enhance the country's technological self-reliance with particular reference to Government's policy on foreign collaboration and import of technology[12]. With a view to achieving techno-economic development, India has adopted a two-pronged approach –

(i) development of indigenous R&D for building up an infrastructure for the transfer and application of technology towards industrial development; and
(ii) acquisition and transfer of technology from abroad and its gradual absorption, adaptation and dissemination in the prevalent system[13].

The development of S&T in India has been on the one hand, in relation to the great advances that have taken place in S&T in the world as a whole, and to the compulsion of ensuring that it is relevant and serves the overall purpose of the development of the country, on the other hand. The task has been formidable for a country like India with its large size and vast population. The efforts have met with real success in many areas and have provided experience in a few others – leading to capacity and capability buildings in S&T in the country.

Grey areas

The exchange of signals between the S&T policy regime and the other regimes has been influenced strongly by the perception of the political leadership and by S&T decisions on the nature and the extent of overlap between different regimes. These perceptions form constituencies of decision makers that are willing to effect adjustment and accommodation by accepting or ignoring signals from different policy regimes[14–16]. For example,

a) Table 1 indicates that there are some policy statements, while others are Resolutions and/or are Acts for the development and management of S&T in the country.

These declarations have different legal powers and jurisdiction and interpretations, whereas some of these have even non-statutory obligations[7].

b) Scientific Policy Resolution (SPR) was adopted in 1958, while the Technology Policy Statement (TPS) was announced, 25 years later in 1983, with the basic objective of developing the indigenous technology appropriate to national priorities and resources, thus leading to self-reliant economy in the country.

The SPR envisaged 'Effective utilization of the human and material resources through industrialization'.

The emphasis has been on the development of the scientific base, expertise, and scientific temper. Evidently, the object was to develop scientific capabilities and manpower as well as awareness among the general masses.

The TPS stressed on 'self reliance' based on protected economy which guided the planning as well as R&D involvement for the past decades or so.

In order to protect indigenous technology, it stipulated, 'Technology acquisition from outside shall not be at the expense of national interest. Indigenous initiative must receive due recognition and support'.

A draft paper for a new Technology Policy Statement was circulated, in 1993, to the scientific community seeking their comments, towards further strengthening the technology base and to assist the nation in fulfilling its role in the global economic environment with confidence and a sense of urgency. This is still under revision.

c) The Industrial Policy Resolution was first announced in 1948. It was later modified several times say in 1956, 1969, 1973, 1977, 1980, 1990 and 1991, keeping in view the changes taking place in the industrial scene abroad and fine-tuning it with the demands towards global competition.

Though New Industrial Policy (NIP), 1991 emphasizes self-reliance and development of domestic technology through investment in R&D, 'self-reliance' here implies the ability of Indian industry 'to pay for inputs through its own foreign exchange earnings'.

It expects 'foreign investment would bring attendant advantages of technology transfer, marketing experience, introduction of modern managerial techniques and new possibilities for promotion of export and inject the desired level of technological dynamism in Indian industry' and the 'Greater competitive pressure will also induce our industry to invest much more in R&D than they have been doing in the past'.

Clearly, in the absence of market competition, the Indian industries belied the expectation of the Government of India categorically stated in the TPS 1983, 'There shall be a firm commitment for absorption, adaptation and subsequent development of imported knowhow through adequate investment in R&D to which inputs of technology will be expected to contribute'.

The delicensing, deregulation, decontrol and abandonment of import substitution strategies adopted in the NIP envision progressively decontrolled market-driven economy and global technical interdependence. It is, thus, a complete departure from the earlier concept and in reality opens up the Indian industry to foreign investment and technological collaboration.

In a major shift from the policy on public sector, it specifies that 'public sector will continue to play a pivotal role in technology development and building of manufacturing capabilities in areas which are crucial in the long-term development of the economy and where private sector investment is inadequate'.

d) The Technology Policy Statement (1983) advocates for the selective import of technology for the promotion of indigenous one while the New Economic Policy (1991) stresses the need for the free/liberalized import of technology and technological products in the country.

e) The Technology Development Fund, launched in 1996 demands the payment of 5% of royalty on the import of technology (by amending the R&D cess Act of 1986) while there is no such levy on the import of new technological products – which are made liberal under the new economic policy of India.

f) India does not have any policy for environment protection while there exist a few policy measures as regulations/acts for the protection of air, water, forest resources, noise, etc. separately. Several laws relating to the management of environment and environmental resources do not clearly state the social objectives they aim to achieve. Consequently, the interpretation of the administrative machinery implementing the legislation is often not in conformity with the intent and purpose of the law.

Some laws, particularly on land use and management of environmental resources, appear to have self-defeating social objectives. Where such resources are shared by more than one state, legislation enacted in one state may have adverse environmental implications for a neighbouring one. India needs an integrated approach to its forestry, with a national, well thought-out policy if it is to undo the damage inflicted on its forest land heritage by a long legacy of neglect.

g) There are a few areas of contradictions or overlapping in the policy statements for the growth of industry and environment, environment and housing, forestry and paper industry, etc. For instance, the growth of human settlement and industrial expansion would cause scarcity on the available land-resources and affect the environment. Similarly, the expansion programme of textile industry needing bleaching and dying chemicals – the exodus of its waste water into river would cause pollution of the rivers – thus one impeding the growth of the other.

h) The attainment of self-reliance has been the motto before the policy-planners in India so far. Self-reliance has eroded the spirit of competition, while the present scenario demands targetting beyond self-reliance, resulting thereby in achieving technological excellence in the global market.

i) The absence of

- coordinating of scientific efforts and infrastructure,
- proper linkages among the academic, R&D and industrial sectors,
- goal-oriented policy towards commercial instinct of R&D efforts, and

- Prioritization in science and technology programmes, have crept in great measures in the S&T system, resulting thereby in its 'just' good performance[17].

Thus, various science policy declarations of India have indicated grey areas depicting a wide scope for new subject function oriented policy instruments. This points towards evolving a comprehensive S&T policy for the overall development of future S&T system in India.

Institutionalization of policy instruments

Science and technology policy and plans cannot succeed unless efforts are made to develop the necessary S&T infrastructure, for performing R&D, developing manpower, determining and deploying instruments, providing feedback, monitoring performance, performing technology assessment and forecasting, creating technology culture, coordinating R&D efforts and providing technological information.

The process of policy declarations and the institution-building, for implementation purposes, in science and technology in India has emerged, at different periods of time, respectively (Table 2). Normally, it is expected that when a policy statement is announced on a subject first, its importance and application should then find stress/focus in the current national Five-Year Plan, aspiring its implementation through the building of a scientific infrastructure in the country. But on the contrary, this approach has not happened in India and a 'disorder' in the S&T system has occurred, i.e. either a policy statement has appeared first, and/or the subject has not received enough promotion in the Plan Document and sometimes the institution has not been created to implement it immediately or vice-versa[17].

Besides, there are several subject-oriented laboratories which are not at all associated with the relevant/concerned Ministries. And, many like-mandated S&T institutions are preferring to work in isolation, rather than working in tandem – for unclear reasons. A national coordination body, say, a National Science and Technology Commission may be established[17,18] which could 'synchronize' the science advisory policy instrument and the creation of organizational structure with the national commitment in plan S&T component/emphasis as indicated in the national Five-Year Plans so that the entire science planning exercise gears towards accruing all the benefits of science and technology to the masses as well as leading to economic development in India. The present liberalized economic and industrial policy allows free import of technology and inflow of foreign investment. The Indian technologies are therefore facing greater challenges in the market. There is a need for an integrated approach for indigenous technology development, which would require study of laboratory level research and different aspects of scale up, technology transfer, commercialization and project financing. Such an exercise will boost the competitiveness of indigenous technologies.

Future perspectives

While examining the strength and weakness of the various science policy declarations of India, several questions have emerged on the surface, for example –

i) What is the relevance of these science policy declarations (Table 1) in the present context, which were announced from time to time, during the past 50 years? As a signatory to GATT/WTO, how will India introduce amendments in the Patent Law (1970) in product vs process patent regime, or Environment Protection Act (1986) in accepting the dumping of waste materials of the developed countries?
ii) How will the free flow of technology and investment from MNC affect the technology base in the country? implying India's emphasis on basic vs applied research in the future.
iii) How long would the R&D institutions act as satellite laboratories for the developed world in (a) carrying out the assigned jobs, (b) generating and supplying educated and trained technical manpower, and (c) preparing the qualified personnel to suit the employment requirements of MNC in India?
iv) When will India start employing/developing capabilities and capacities to manage the challenges of the frontier areas in science or new and emerging technologies?
v) Since economic and trade policies would now govern the bilateral cooperation in science & technology, industry, etc., further amendments would be needed in the policies which were framed yesterday to enable these to become strong and relevant today and tomorrow. (The recent American pressure on Russia not to affect the sale of MTCR technology to India, impeding India's rocket launching programme because of India procrastinating in signing NPT, GATT/(WTO)/Patent Law testifies the main statement.) There will be a demand for patent information after liberalization in India, with a view to developing and promoting indigenous technology and to avoid repetitive import of costly technology from abroad[19–22]. Besides, emphasis on R&D for technological innovations would aid India on the decreasing import of new generation technologies from abroad.

So, what would be the impact of liberalized economy for technology transfer and its commercialization in India over the existent technology base and spirit of the people? The S&T system would then require some fine-tuning in relation to the emerging scenario of international developments[23].

Table 2. Disorder in the institutionalization of Science & Technology policies in India

Policy declarations (year)	Creation of an institution (year)
Scientific Policy Resolution (1958)	Ministry of Science & Technology (set up in 1951, and 1985)
Technology Policy Statement (1983)	Technology Policy Implementation Committee (1984) Department of Scientific and Industrial Research (1985) Technology Information, Forecasting and Assessment Council (1988)
Environment Protection Act (1986)	Department of Environment (1980) (now) Ministry of Environment and Forest
Energy Policy Statement (1980)	Department of Non-Conventional Energy Sources (1982), (now Ministry of Non-Conventional Energy Sources)
Ocean Policy Statement (1984)	Department of Ocean Development (1981)
R&D Cess Act (1986)/ Fund for Technology Development and Application (1995)	Industrial Development Bank of India Department of Science & Technology (1971) Technology Development Board Act (1996)

To conclude, we need a reorientation of the policies to meet simultaneously the challenges of an internationally competitive economy and to provide satisfaction of rendering basic human needs to the population. An integrated science and technology policy must have three-fold objectives: Help India to emerge as an internationally competitive economy; effectively meet the needs of national security and be an active instrument of human emancipation; laying particular emphasis on meeting the basic needs of all our people[24]. Science and technology policies must be so designed as to actively assist India emerging as a strong and internationally competitive economy. The vision that must inspire us is that, in less than a decade, we should complete the transition from being a developing economy, to becoming a developed country, able and willing to face the challenge of global competition on an equal footing. Science policy in India has been evolved due to the appreciation of role of S&T for economic development by the political leaders as well as the generation of foresight studies which have pointed out towards the strength–weakness analysis of the existing S&T system and enabling India to undertake appropriate measures[25–27].

In order to attain global competence, an integrated approach to science policy declarations would be required, in respect of deciding priorities over capital intensive vs labour intensive technology – a factor that is very important for a developing country, like India, with meagre resources and large manpower. It would also require goal-oriented policy for setting 'targets beyond self-reliance', as the industrial scenario demands global competition and significant outward-looking economy, atleast in a few areas of techno-economic importance.

A coordinated and concerted effort among several policy measures when adopted, along with consolidated programmes and prioritization, for establishing a new science vision and yielding meaningful results for the prosperity of India, would be required for keeping alive her interests at the national and international levels – certainly an example for the developing countries to emulate for avoiding pitfalls!

Sister chromatid cohesion during meiosis: Differential mechanisms for arms and centromere coherence

Amit Bardhan

Department of Zoology, Banaras Hindu University, Varanasi 221 005, India

Sister chromatid cohesion is a fundamental aspect of chromosome behaviour which ensures faithful disjunction of chromosomes. The differential release of centromeric- and arm-cohesion during meiosis suggests that the molecular basis of cohesion in the two domains might be different. A number of meiotic mutations differentially affect cohesion in the two domains. Recent identification of two proteins, ORD and mei-S332, shows that they are involved in maintaining cohesion in two spatially different locations. While mei-S332 acts to structurally hold the sister centromeres together until second meiotic anaphase, ORD is likely to time the release of cohesion along the arms during first meiotic division.

HAD there been no physical connection between the replicated chromatids, the so-called sister chromatids, recognition of the sisters and their subsequent segregation during divisional cycle would have been an extremely complex process. Perhaps to sidestep such a complexity, the cell has evolved an apparently simple mechanism by which the sister chromatids are kept in association right from their replication in S phase. The term sister chromatid cohesion refers to this physical bonding between the replicated sisters. Fidelity of chromosome segregation in mitosis relies on the maintenance of cohesion between the sister chromatids until anaphase transition. The tension generated as a result of the interaction of sister kinetochores with spindle poles and the opposing force imparted by cohesion (between the sisters) leads to the stable bipolar arrangement of chromosomes on metaphase spindle[1]; cohesion is relieved at the onset of anaphase to enable the two sisters to move to opposite poles. In contrast to mitosis where both the centromere and arm cohesion are dissolved simultaneously, the specialized cell division of meiosis requires a *differential release of cohesion* (Figure 1). Meiosis involves two rounds of nuclear divisions following a single premeiotic S phase and results in halving the chromosome number. During the first (reductional) meiotic division homologous chromosomes segregate from each other, while during the second (equational) division of meiosis, sister chromatids disjoin. Cohesion at the centromere is maintained throughout the first meiotic division so that the two sisters are constrained to move to the same pole during anaphase-I, and only at the onset of anaphase-II the centromeric cohesion is released allowing the sisters' migration towards opposite poles. On the other hand, cohesion along homolog arms helps stabilize and maintain chiasma position[2,3], thereby enabling the bivalents to achieve a stable bipolar orientation on the metaphase-I spindle to secure reductional disjunction during anaphase-I. The arm cohesion is dissolved at metaphase-I/anaphase-I transition presumably for the release of chiasmata. Thus, sister chromatid cohesion has a two-fold significance in meiosis as compared to mitosis, to secure reductional disjunction of homologs during first meiosis and also equational segregation of the sisters during the second meiotic division, and a defect in either of the two might lead to aberrant segregation resulting in nondisjunction.

A variety of mechanisms have been proposed to explain cohesion between sister chromatids. The hypothesis that the late replicating centromeric DNA might serve to hold the sisters together proved to be untenable with the finding in budding yeast, *Saccharomyces cerevisiae* that centromeric DNA is fully replicated well ahead of the time of chromosome segregation[4]. The idea that catenation produced during DNA replication could play a role in physically holding the chromatids together[5] has received experimental support with the finding that DNA topoisomerase II (the enzyme which reversibly untangle interlocked DNA duplexes) activity is required for anaphase transition[6,7]. Also, topoisomerase II has been shown to be required for segregation of recombined chromosomes during first division of meiosis[8]. In addition to catenation that interlock two DNA helices (comprising the two sister chromatids), some protein(s) may act to reinforce cohesion as suggested by recent evidences, and they may function either as structural proteins gluing the sisters together, or as regulatory proteins in timing the release of cohesion.

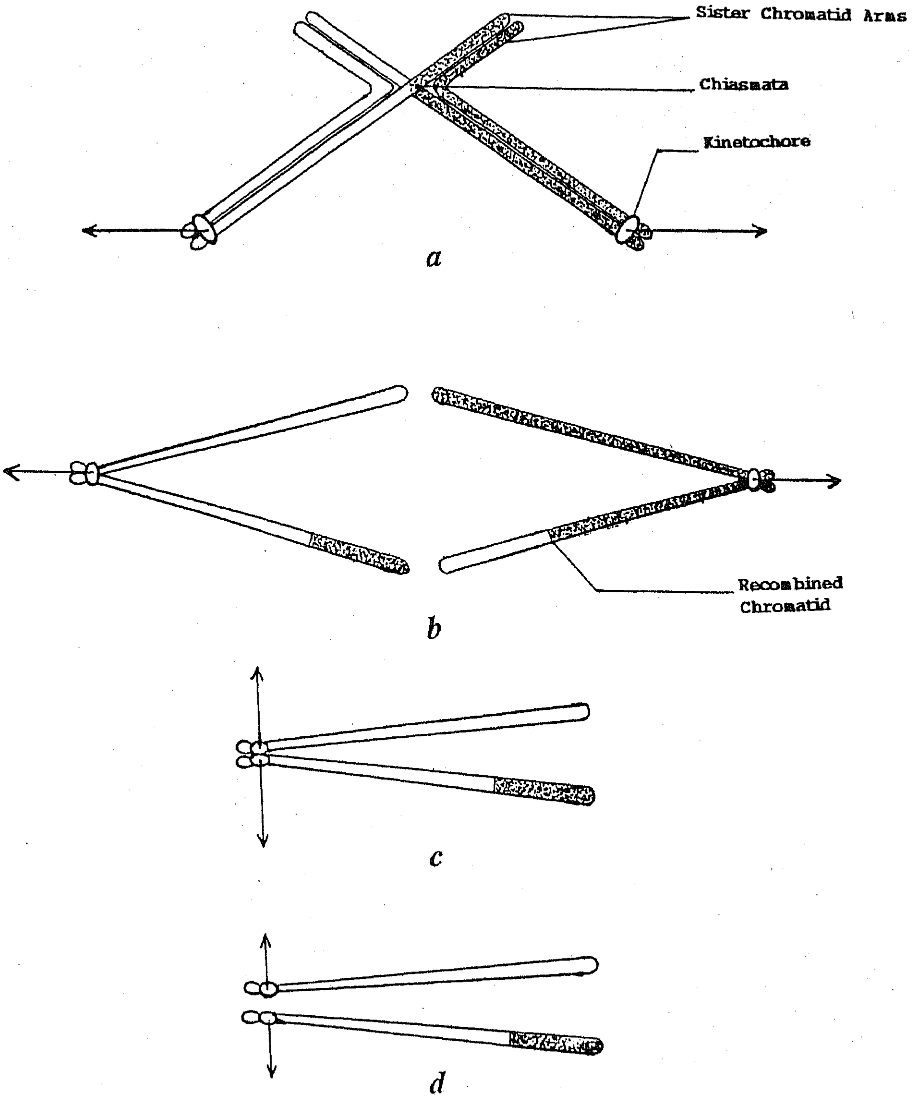

Figure 1. Chromosome behaviour during meiosis. *a*, A pair of homologous chromosomes (bivalent) connected by chiasmata, at metaphase-I. Sister chromatid cohesion is maintained both at the centromeres and along the arms; *b*, At anaphase-I, arm cohesion is dissolved (indicated by the gap between the chromatid arms) allowing the release of chiasmata, and the two homologs move to opposite poles; *c*, At metaphase-II, sister kinetochore differentiation occurs and they capture spindle microtubules from opposite poles; *d*, At anaphase-II, cohesion between the sister centromeres is released, allowing the sisters' migration towards opposite poles. In *c* and *d*, only one of the two homologous chromosomes is shown. In all the figures, arrows indicate the direction of 'pull' exerted on the kinetochore by spindle microtubules.

They include the gene products identified by a number of mutants defective in sister chromatid cohesion, and proteins identified by antibodies (see ref. 9 for a review). While catenation could provide the physical basis of cohesion that is common to both mitotic and meiotic chromosomes, the function of these proteins might be specific to either of the two divisions.

The differential release of centromeric and arm cohesion during meiosis suggests that different proteins might be involved in maintaining cohesion along the chromosome arms and at the centromere, and their mode of action might be mechanistically different. Alternatively, the same protein(s) might be shared in both the domains and only their removal/destruction is regulated differentially. That the molecular basis of cohesion at the centromere and along the arms could be different is also evident from the phenotypes of *Drosophila pim* and *thr* mutants. The *pim* and *thr* gene products are specially required for the release of cohesion between sister centromeres, but not between the arms, during mitosis[10,11].

This review addresses the probability that the mechanism of maintenance of cohesion might be different at the centromeres and along the chromatid arms, at least during meiosis. To do this, we will survey some of the potential candidate cohesion genes which act in meiosis and try to examine whether their action is restricted to either of the two chromosomal domains (i.e. the centromere and the chromatid arms). We then discuss the identified cohesion proteins and the possible mechanisms of their action. Though the gene products which affect cohesion during mitosis are significant in their own right, they will not be discussed here for the sake of brevity.

Potential sister-chromatid cohesion mutations

Non-disjunction in meiosis-I might occur in either of two ways: absence or reduction of reciprocal genetic exchange (for a review, see ref. 12), or failure in maintenance of chiasmata. Although the mechanism of chiasma maintenance is still a matter of dispute (reviewed by Carpenter[13]), cohesion between sister chromatids could be one of the major contributing factors[3]. The reduced genetic exchange, or early loss of chiasma (or both), could lead to formation of univalents in diakinesis/metaphase-I and subsequent random movement of the univalents on first meiotic spindle. On the other hand, mis-segregation in meiosis-II might result from precocious release of cohesion between the sister centromeres followed by their independent movement, and an earlier incidence of failure of genetic exchange does not seem to affect anaphase-II segregation. However, it is known that presence of univalents in metaphase-I spindle could delay anaphase transition and the univalents could segregate equationally; the resulting sisters again mis-segregate during second meiosis. Therefore, it seems difficult to specify whether a nondisjunction event results primarily from a failure of cohesion, or is a manifestation of reduced genetic exchange. The cases where recombined chromosomes mis-segregate might be informative, and could be the result of precocious dissociation of sisters, since here the resulting (from recombination) chiasmata fails to bind and (thus) to regularize disjunction. However, an early dissociation (between sisters) event could affect recombination by affecting homolog association, thus making it probable that mis-segregation of non-recombinant chromosomes could result primarily from lack of cohesion instead of lack of genetic recombination *per se*. Identification of genes which regulate meiotic cohesion has been done by isolating mutants that mis-segregate during meiotic division(s). Though a direct visual observation of chromosome behaviour in mutants could undoubtedly demonstrate the involvement of a specific gene in cohesion, identification of genes has been hindered by poor chromosome morphology in systems which offer a powerful genetic tool, e.g. the yeast and *Drosophila*, although in the latter case the male meiosis has made cytological approach amenable. Therefore, to understand the involvement of specific genes in cohesion, we will survey some meiotic mutations (Table 1) which result in mis-segregation during meiotic division(s), and examine the likelihood that the primary defect is at the level of sister chromatid cohesion. Special emphasis will be put on situations where recombined chromosomes mis-segregate, and, where recombination frequency is not significantly reduced by the mutation.

A number of mutations show a rather pleiotropic effect, affecting frequency of genetic recombination and synaptonemal complex (SC) structure/function, besides affecting chromosome disjunction during meiosis. This group includes the *red1*, *rec8*, *spo76* and *ord*[14–21]. All of them produce highly aneuploid meiotic products. Following the segregation behaviour of a number of centromere-linked heterozygous markers, it has been found that the mutations primarily affect reductional (meiosis-I) disjunction. Majority of the disomes were heterozygous for the centromere-linked markers, suggesting that the mutations affect meiosis-I segregation (non-disjunction in meiosis-II would result in disomes with sister centromeres, rather than with homologous centromeres). Though the mutations reduce frequency of meiotic recombination and thus raise the possibility that non-disjunction results from lack of genetic exchange, genetic analyses have shown that even recombined chromosomes undergo mis-segregation in the mutants[14–16,19,21]. The latter observations suggest that mis-segregation results from failure in maintaining chiasmata which, in turn, might be the consequence of precocious release of cohesion between the sister chromatids early in meiosis-I. Fluorescent *in situ* hybridization analysis of meiotic prophase chromosomes in the *rec8* mutant of fission yeast has shown that sister chromatids get frequently separated during first meiotic prophase[16]. Cytological observations in *spo76* and *ord* mutants also show precocious separation of sister chromatids in early prophase-I of meiosis[18,20,21]. It has also been shown that meiotic synapsis is aberrant in the mutants with defective SC formation[15,18], except in *ord* where synaptic progression has not been analysed. Even in *ord* it is highly probable that meiotic synapsis gets affected, since the mutant reduces recombination frequency. In fission yeast where classical tripartite SCs are not formed, and instead a structure called linear elements (which are thought to be equivalent structure to the lateral element of SC of other organisms) are formed along the length of meiotic prophase chromosomes, formation of the latter also gets affected in the *rec8* mutant[16]. One reasonable possibility could be that component(s) of SC confer sister chromatid cohesion (as suggested by Maguire[22–24]), and deformed (or absence of) SC formation reduces the probability of meiotic recombination. Alternatively, it may be possible that sister

Table 1. Features of the mutations

Mutation	Level of mis-segregation	Recombination frequency	Type of mis-segregation	Meiotic synapsis	Somatic mitosis	Others
Saccharomyces cerevisiae						
red1	Meiosis-I	Reduced	Both recombined and non-recombined chromosomes	No SC assembly	Unaffected	
med1	Predominantly meiosis-I, also meiosis-II	Reduced	Recombined and non-recombined	Normal	Unaffected	
dis1	Meiosis-I	Unaffected	Recombined	Not detected	Increased non-disjunction	
Schizosaccharomyces pombe						
rec8	Meiosis-I; also meiosis-II?	Reduced	Recombined and non-recombined	Aberrant linear element formation	Unaffected ?	
Sordaria macrospora						
spo76	Meiosis-I	Reduced in heterozygotes	Recombined; also non-recombined?	Aberrant	Unaffected ?	Defective in UV damage repair; no meiosis-II
Zea mays						
dy	Meiosis-I; also meiosis-II?	Unaffected	Recombined	Precocious desynapsis	Unaffected ?	
Drosophila melanogaster						
ord	Predominantly meiosis-I	Reduced in females	Recombined and non-recombined	Not detected	Unaffected	Gonial mitosis slightly affected
mei-S332	Predominantly meiosis-II	Unaffected	Recombined	Not detected	Unaffected	Gonial mitosis slightly affected

chromatid cohesiveness is needed for proper homolog association and SC formation, and a defect in the former could lead to aberrant SC formation with reduced genetic recombination. However, the pleiotropic nature of the mutations suggests that they might as well be some regulatory components of meiosis, parallely affecting different meiotic events independent of each other. Indeed, isolation of one allele of *ord* (*ord*^{6}) that affects recombination to the same extent as do the other alleles but affects disjunction less frequently[21] suggests that the gene can differentially influence the two processes, strengthening the direct involvement of the gene in maintaining cohesion.

The yeast *med1* mutation is also somewhat similar to the above discussed ones in the sense that it results in high level of meiosis-I, and to some extent meiosis-II, non-disjunction, and also reduces frequency of recombination[25]. But, in contrast to the mutations already described, SC formation is apparently normal in the *med*^{1} mutant[25]. Increased spore viability of *med1 spo13* double mutant suggests that *med1* function is required for reductional division of meiosis[25] (the *spo13* mutant undergoes a single meiotic division of predominantly equational nature; thus, meiotic lethal mutants which are defective in recombination produce viable meiotic products in a *spo13* background since *spo13* skips first meitoic division[26]). Although reduced recombination elevates meiosis-I non-disjunction in the mutant, a good number of the disomes result from precocious separation of recombined chromatids followed by their random segregation through both meiotic divisions[25]. Though it has been suggested that the defects in cohesion as well as recombination are secondary consequences of perturbed chromatin structure caused by the mutation[25], it cannot be ruled out that MED1 is a regulatory protein independently affecting cohesion and recombination. It may even be possible that MED1 function is required specifically for arm cohesion and a defective cohesion along the arms reduces probability of meiotic recombination by affecting homolog association in early meiosis-I. The *med1* mutant phenotype appears to be very similar to that of *ord* in *Drosophila*. Cloning and sequencing of *med1* will show whether the gene is homologous to the *Drosophila ord* gene.

Another good candidate for meiotic cohesion is the maize *dy* gene. In the homozygous *dy* mutants, sporadic precocious desynapsis of bivalents follows apparently normal pachytene synapsis. By diakinesis, bivalents often separate to univalents which lag for some time on the spindle and then segregate equationally during anaphase-I[27,28]. Frequency of meiotic crossing-over appears to be unaffected in the mutant (a distal heterozygous marker, a heterochromatic 'knob', was found to be separated equationally in most of the cases, confirming the occurrence of an exchange event between the knob and the centromere[28]). The inferred crossover frequencies in the mutant were equal and consistent with the expected wild type crossover frequency. The results show that the mutation has no apparent effect on meiotic recombination but it affects maintenance of chiasmata. Ultrastructural observations of synaptic progression showed that the central region of the SC disintegrates early, causing precocious desynapsis in the mutant. It has been suggested that one of the late functions of SC is to provide for sister chromatid cohesion, and that the lack of sister cohesiveness results in early loss of chiasmata[22–24, 27–29].

The yeast *dis1* and *Drosophila mei-S332* mutations apparently affect cohesion specifically at the centromere region, but the time of their expressions differs. While *dis1* predominantly affects meiosis-I segregation[30], *mei-S332* impairs meiosis-II disjunction[20,31,32]. Both the mutants have no apparent effect on recombination[30–32], suggesting that they do not interfere with homolog association, and non-disjunction involves almost all the chromosomes of the complement. Genetic analysis in *dis1* suggests that non-disjunction results from precocious separation of sister chromatids at meiosis-I followed by their equational, rather than random, segregation[30]. Cytological observation of meiotic segregation in *mei-S332* mutant males reveals that sister chromatids frequently dissociate in mid- to late-anaphase-I, resulting in non-disjunction or lagging chromosomes in anaphase-II[20,31,32]. The results suggest that although both the mutations affect specifically the centromeric cohesion (disrupted cohesion along the arms would reduce the probability of exchange event), the mechanism of their action most likely differs. *Dis1* might act to regulate functional differentiation of sister kinetochores, and an early differentiation in the mutant leads to premature separation of sister chromatids (if *dis1* were to maintain cohesion after sister kinetochore differentiation, the mutant would cause only meiosis-II non-disjunction). On the other hand, *mei-S332* is likely to act to physically hold the sister kinetochores, after their functional differentiation at prometaphase-I and early anaphase-I. *Dis1* differs from *mei-S332* in another respect, in that, it induces high level of mitotic non-disjunction as well[30], suggesting that *dis1* function might be shared between the two types of nuclear divisions.

It seems probable that a number of mutations could affect cohesion along the chromatid arms during meiosis, viz. *red1*, *spo76*, *med1*, *rec8*, *dy* and *ord*. All of them (except *dy*) reduce frequency of meiotic recombination, and also affect maintenance of chiasmata. This is expected from an aberrant association between the arms of sister chromatids during meiosis-I. A few of them might also act to maintain centromeric cohesion. However, it seems untimely to draw any conclusion about their involvement in centromeric cohesion, except to mention safely that if they are to maintain cohesion at the centromeres, the mechanism might be different compared to what operates for arm cohesion (discussed later).

Molecular mechanism of cohesion during meiosis

Recent identification of two proteins from *Drosophila*, mei-S332 and ORD, which are shown to be involved in maintaining sister chromatid cohesion in meiosis has provided a critical insight into the molecular basis of cohesion[33,34].

Kerrebrock *et al.*[33] have cloned the *Drosophila mei-S332* gene and have shown that the gene encodes a novel 44 kDa protein. Genetic and cytological analyses suggest a role for the protein in promoting cohesion specifically at the centromere region, after differentiation of sister kinetochores. This has been corroborated by the localization of the mei-S332 protein (fused to jelly fish Green Fluorescent Protein) on meiotic chromosomes. The localization pattern of the protein (on meiotic chromosomes) is consistent with the idea that the protein functions as a structural component to hold the sister centromeres together. Mei-S332.GFP localizes to the centromeric region of the meiotic chromosomes, starting from prophase-I onwards until metaphase-II (ref. 33). Strikingly, at the onset of anaphase-II the protein suddenly disappears from the centromeres and is no longer detectable[33], which is consistent with the requirement for the release of cohesion if the protein is to act to physically hold the two sisters together.

The *Drosophila ord* gene has been cloned and shown to encode a novel 55 kDa protein[34]. *Ord* transcribes only in adult ovary and testis, and in no other tissues or developmental stages, suggesting its meiosis-specific function. The low abundance of *ord* message suggests that the protein is likely to maintain cohesion in a regulatory manner, rather than as a structural component[34]. The effect of *ord* mutation on meiotic recombination is consistent with a regulatory role of the protein. Some of the *ord* alleles exhibit a unique phenomenon of negative complementation where one allele poisons the activity of another. When the mild allele ord^4, which retains a high amount of residual activity even in *trans* to a deficiency for the locus, is placed *trans* to some other *recessive* alleles (ord^1, ord^2, ord^6), the level of malsegregation increases significantly[34]. However, other recessive alleles (ord^3, ord^5) do not interfere with residual function of ord^4. Sequence analyses have shown that in ord^1, ord^2 and ord^6 (which impair ord^4 function), the mutations residue in the C-terminal halves of the proteins, while the ones that do not interfere with ord^4 function lack the C-terminal halves from missense mutations. This suggests that the C-terminal half of the protein is crucial for its function. Bickel *et al.*[34] have suggested that functioning of ORD requires protein–protein interaction through C-terminal halves. They have proposed that the ORD protein is having two functional domains, one for protein binding and another for exert-ing cohesion function, and that cohesion requires binding but binding does not ensure cohesion (see Figure 5 in ref. 34). Since ORD dimerization could not be detected, it is most likely that the protein interacts with some other protein molecule, which is yet to be identified[34]. The alleles which poison the activity of *ord*[4] might have altered 'cohesion domain' but intact 'protein binding domain' and form non-functional complex with the interacting partner, thus outcompeting *ord*[4] (which might have slightly altered 'protein binding domain' but intact 'cohesion domain') to form functional complex with the protein partner[34].

Another protein, Cor1, isolated from hamster has been suggested to maintain cohesion on the basis of observation that it localizes between sister chromatids of meiotic chromosomes (but not mitotic chromosomes)[35]. Cor1 is a component of the lateral element of SCs (ref. 35), and its localization pattern on meiotic chromosomes is consistent with a role of the protein in maintaining cohesion until second meiotic anaphase. Cor1 has been shown to localize axial to metaphase-I chromosomes with a substantial amount in association with pairs of sister centromeres. Interestingly, the centromeric Cor1 persists up to metaphase-II and dissociates at the onset of anaphase-II, which suggests that the protein might have a role in ensuring co-segregation of sister chromatids at anaphase-I (ref. 35). However, the evidence is rather correlative and it seems difficult to analyse directly the involvement of Cor1 in sister chromatid cohesion. However, the large body of circumstantial evidences for a role of some SC components in imparting cohesion is consistent with the role attributed to Cor1.

Concluding remark

A handful of potential candidate genes have been identified from diverse organisms, but till date only two candidate proteins could be identified which are unambiguously involved in maintaining sister chromatid cohesion during meiosis. With the identification of mei-S332 and its localization on meiotic chromosomes, it is evident that this particular protein is required specifically to maintain centromeric cohesion during meiosis, and the gene product has no apparent contribution in maintaining arm cohesion. On the other hand, the *ord* mutant phenotype manifests at a time when arm cohesion is very crucial (for maintaining chiasmata), and it is most likely that the ORD protein acts to maintain cohesion at least along the chromatid arms. Though mei-S332 localizes to meiotic chromosomes from prophase-I onwards, the mutant phenotype expresses very late, at a time when the sister kinetochores are functionally duplicated. It is probable that during first meiotic division, maintaining cohesion at the centromeres is not very crucial (as the sister kinetochores are not differentiated, see Goldstein[36]), and ORD can very well maintain the structural integrity of bivalents, even in absence of mei-S332, to secure proper reductional disjunction. Only when the sister kinetochores differentiate, proper functioning of mei-S332 becomes crucial to physically hold the two sisters together until anaphase-II transition. There is some evidence that ORD could promote centromeric cohesion as well[21]. However, the mechanisms of its functions at the centromere and along the chromatid arms might be different, and requires that during metaphase-I/anaphase-I transition function of ORD be preferentially removed from the chromatid arms while at the same time be retained at the centromere. It may be possible that different forms of ORD exist and their function might be mechanistically different[34]. ORD along chromatid arms might act through regulating the release of topoisomerase II inhibition, while ORD at the centromeric region might regulate functional duplication of sister kinetochores (the release of arm cohesion requires topoisomerase II, but the activity of the enzyme has been shown to be dispensable for the release of centromeric cohesion; see ref. 37).

Mutational analyses have shown that different centromeric sequences differentially affect the segregation behaviour of yeast mitotic and meiotic chromosomes. While some sequences are required for sister chromatid cohesion and faithful segregation of chromosomes during meiosis, others are important for fidelity of mitotic disjuction[38–44]. Recently, Murphy and Karpen[45] have carried out molecular and functional characterization of *Drosophila* centromere on a minichromosome, Dp1187. They have shown that besides the sequences which are necessary for minimal centromeric function, an additional ~200 kb of heterochromatic pericentromeric sequences on either side of the minimal centromere is required for faithful disjunction of chromosomes. Moreover, partial deletion of the ~200 kb repetitive sequence differentially affects segregation of chromosomes in male and female meiosis, which suggests that there are meiosis-specific functions residing in the pericentromeric heterochromatin. They have proposed a model in which the ~200 kb heterochromatic sequences are involved in maintaining sister chromatid cohesion by binding with cohesion proteins (Figure 7 *a* in ref. 45). The model is consistent with the demonstration that heterochromatin is involved in meiotic chromosome segregation[46]. Sekelsky and Hawley[47] have suggested that the mei-S332 protein might bind to the ~200 kb pericentromeric heterochromatic sequences to exert its function. However, such a binding is yet to be demonstrated. This can be done by examining the binding of mei-S332 *in vitro* to the -AATAT- satellite which comprises the ~200 kb pericentromeric sequences. Alternatively, localization of the protein on derivatives of Dp1187 might clarify this point. Lastly, it needs to be determined whether the removal of the function of mei-S332 and

ORD requires degradation of the proteins. The abundance of PEST sequences in both the proteins has been implicated as an indication that the proteins might undergo degradation at the onset of anaphase transition, through an ubiquitin independent pathway[33,34].

The recent identification of two proteins involved in maintaining cohesion between sister chromatids promises a better understanding of some basic aspects of meiosis research, particularly, the factor(s) determining chromosome segregation and the mechanism of chiasma binding. The molecular analysis of centromere function in *Drosophila*, and the identification of ORD and mei-S332 proteins has already laid the foundation for the identification of additional protein(s) which might be involved in maintaining sister chromatid coherence.

Potential application of RAPD and RAHM markers in genome analysis of scombroid fishes

P. Jayasankar and K. Dharmalingam*

Central Marine Fisheries Research Institute, P.B. No. 1603, Tatapuram, Kochi 682 014, India
*School of Biotechnology, Madurai Kamaraj University, Madurai 625 021, India

Total genomic DNA from 30 different specimens of Indian mackerel *Rastrelliger kanagurta* (Cuvier) and 5 king seer *Scomberomorus commerson* (Lacepede) was extracted by a simple modified phenol–chloroform protocol. PCR amplification conditions using 10-mer arbitrary primers were optimized. Primers with the same nucleotide sequences produced varying Random amplified polymorphic DNA (RAPD) patterns and those with different sequences generated different banding patterns for the same template in the two commercially important scombroid fishes. Primer OPA 07 (GAAACGGGTG) yielded more polymorphic loci with high reproducibility. Better performance of the primers from Kit A (Operon Technologies, Inc) is attributed to their high G + C content. RAPDs were highly sensitive to the concentrations of primer, $MgCl_2$ and the brand of *Taq* DNA polymerase enzyme. Random amplified hybridization microsatellites (RAHM) can overcome the inherent shortcomings of RAPDs.

Random amplified polymorphic DNA (RAPD) is a novel technique of revealing DNA-based arbitrarily primed polymorphisms[1,2]. Compared with multilocus fingerprinting using microsatellite probes, the RAPD markers are more useful in discriminating populations since they are less variable over generations[3]. RAPD was found to be technically easier with low statistical error, whereas multilocus fingerprinting with 33.15 probe detected more genetic differentiation among strains of *Oreochromis niloticus*[4].

RAPDs have been particularly useful in the genetic fingerprinting of plants[5]. They are used for creating linkage maps, locating disease resistance genes and for identifying chromosome-specific markers. This PCR-based fingerprinting has begun to find application in fish and shellfish genetic analyses. RAPDs were used to detect radiation-induced DNA damages in *Oryzias latipes*[6]. Fingerprinting of 12 species of fishes using arbitrary primer PCR was reported[7]. The technique was applied for species and subspecies identification of *Oreochromis*[8]. Seven hundred and twenty one RAPD polymorphisms were identified between two laboratory strains of zebra fish, *Danio*[9] and 401 of them were used to construct a genetic linkage map[10]. Genetic variations in samples of seabass, *Dicentrarchus labrax* before and after acclimation to freshwater were investigated[11]. Inheritance of RAPD markers in the F_1 progeny of single-pair crosses between two guppy (*Poecilia reticulata*) varieties was studied[12]. Three polymorphic markers were observed out of a total of 48 RAPD loci amplified by 14 arbitrary primers in penaeid prawn *Penaeus monodon*[13].

Random amplified hybridization microsatellites (RAHM) is a new system for microsatellite DNA detection and isolation which combines RAPD amplification and oligonucleotide screening[14]. A similar technique known as *R*andom *A*mplified *M*icrosatellite *PO*lymorphisms (RAMPO) is described[15]. The rapid use and acceptance of microsatellites as genetic markers is due primarily to their comparative ease of assay via PCR

and accuracy of scoring allelic types[16]. In the present study, we have optimized conditions for generating RAPD markers of two commercially important scombroid fishes and attempted RAHM technique potentially useful to discriminate fish populations. DNA samples from 30 different specimens of Indian mackerel *Rastrelliger kanagurta* (Cuvier) and 5 specimens of king seer *Scomberomorus commerson* (Lacepede) were analysed.

Materials and methods

Fish and tissue sampling

Specimens of Indian mackerel of total length range 140–250 mm were collected from commercial gill net landings at Mandapam, Mangalore and Fort Kochi and those of king seer from Mandapam during 1995–96 (Figure 1).

At Mandapam, either liver or muscle was dissected out from the fishes soon after their landings and transported to the laboratory in one of the three following media: (a) crushed ice, (b) lysate buffer (1 M Tris HCl pH 8.0; 0.4 M EDTA pH 8.0; 2% SDS), (c) 95% ethanol. Muscle samples of Indian mackerel from Fort Kochi and Mangalore fish landing centres were preserved and transported in 95% ethanol. In the laboratory all tissues were immediately stored at –70°C until DNA extraction. Total genomic DNA was extracted from 11, 11 and 8 different individual mackerels from Mandapam, Mangalore and Fort Kochi, respectively and from 5 specimens of king seer landed at Mandapam.

Extraction of genomic DNA

We have developed a simple and efficient protocol to extract total genomic DNA from field-collected fish. The preparation was found suitable equally for PCR and hybridization-based fingerprinting applications. Briefly, 0.4–1.0 g of tissue is placed in a mortar and kept at –70°C for 1–2 h. Use of liquid nitrogen to flash freeze tissue is obviated in our protocol. The frozen tissue is well ground and immediately mixed with homogenizing buffer (100 mM Tris HCl pH 8.0; 10 mM EDTA pH 8.0; 1.4 M NaCl; 1% CTAB; 0.2% mercaptethanol) and incubated with 150 μg/ml proteinase K (Sigma) at 37°C for 4–12 h. This is followed by phenol–chloroform extraction, precipitation of DNA with cold absolute alcohol, vacuum drying and resuspension in TE. RNA is removed by RNase (Sigma) at 250 μg/ml. DNA is then reextracted and resuspended in TE. Quality and quantity of the preparation were checked by agarose gel electrophoresis and spectrophotometry.

RAPD primers

A total of 35 arbitrary primers from A, F and G kits of Operon Technologies, Inc were tried to amplify DNA by PCR. The nucleotide sequences of the primers used in the present work are given in Box 1.

Optimization of primer and $MgCl_2$ concentrations

Initially four different concentrations each of arbitrary primer (0.32, 0.64, 1.28 and 2.56 μM) and $MgCl_2$ (2.0, 2.2, 2.4 and 2.6 mM) were tested to determine the optimum levels of their requirements for DNA amplification. Better resolution was obtained at 0.64 μM of primer and 2.4 mM of $MgCl_2$.

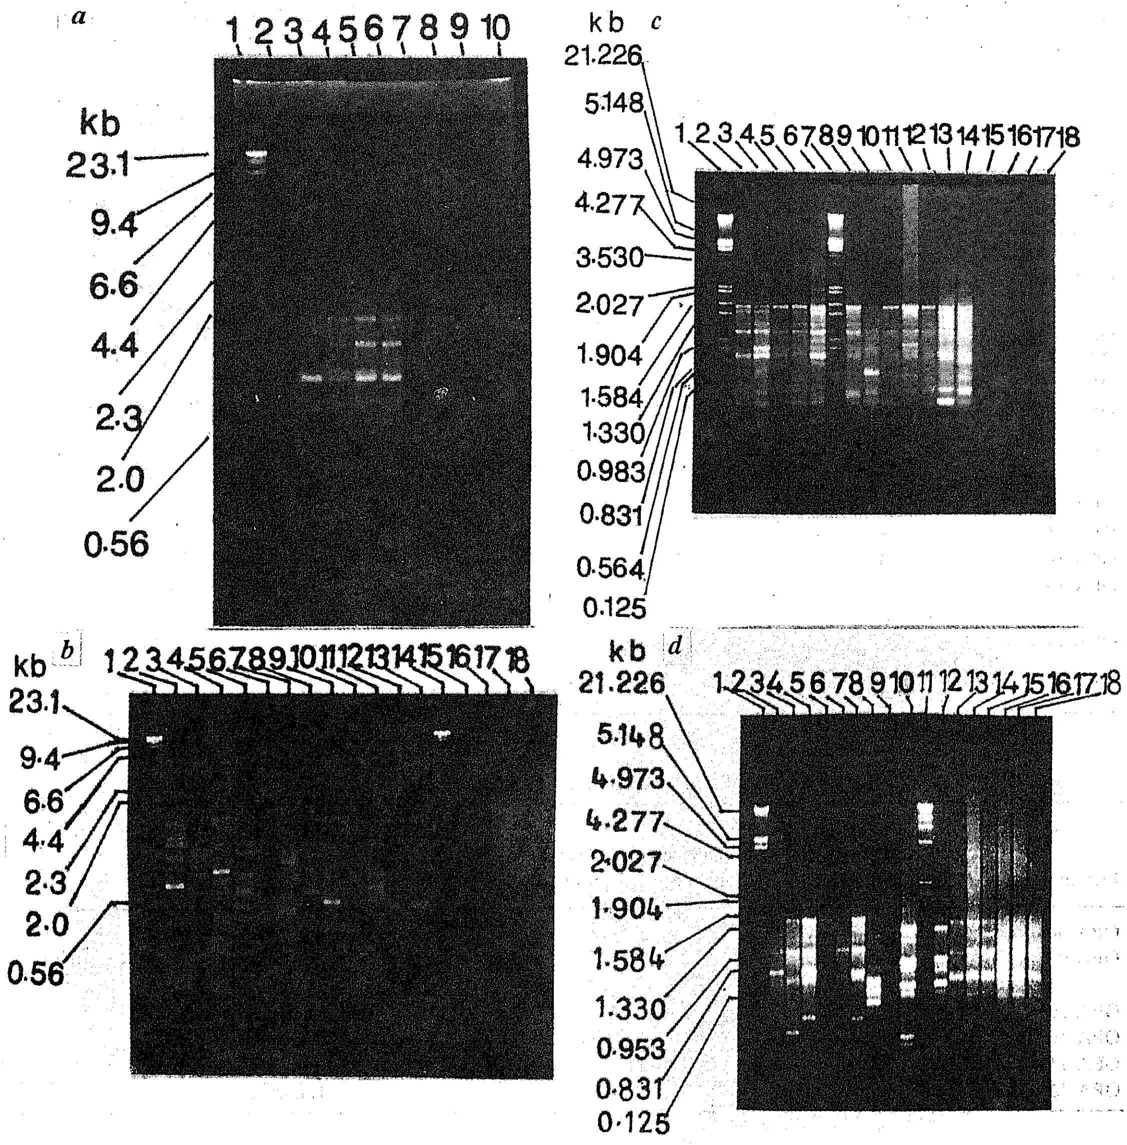

Figure 2. *a*, Effect of varying concentrations of $MgCl_2$ on RAPD patterns in Indian mackerel (*Taq* 1). Lane 1, λ *Hin*dIII; Lanes 2 and 7–10, Blank; Lane 3, 2.0 μm; Lane 4, 2.2 μm; Lane 5, 2.4 μm; Lane 6, 2.6 μm. *b*, RAPDs with OPA, OPF and OPG primers (*Taq* 1). Lanes 1 and 14, λ *Hin*dIII; Lanes 2 and 3, Indian mackerel and king seer DNAs (OPF 01); Lanes 4 and 5, Indian mackerel and king seer DNAs (OPA 07); Lanes 6, 8, 10 and 12, one Indian mackerel specimen (OPG 05, 13, 18 and 20, respectively); Lanes 7, 9, 11 and 13, one king seer specimen (OPG 05, 13, 18 and 20, respectively); Lanes 15–18, Blank. *c*, RAPDs in Indian mackerel generated by OPA 07 (*Taq* 1). Lanes 1 and 7, λ *Hin*dIII + *Eco*RI; Lanes 2 and 3, two specimens from Mandapam; Lanes 4–6 and 8–14, ten specimens from Fort Kochi; Lanes 15–18, Blank, *d*, RAPDs in Indian mackerel generated by OPA and OPF primers (*Taq* 1 except for lanes 16–18). Lanes 1 and 11, λ *Hin*dIII + *Eco*RI; Lanes 2, 3 and 5–7, five specimens from Mandapam (OPA 07); Lanes 8 and 9, two specimens from Fort Kochi (OPA 08); Lanes 13–15, two specimens from Fort Kochi and one from Mandapam (OPF 01); Lanes 16–18, same as 13–15, but used a *Taq* DNA polymerase prepared in our laboratory. The individual DNAs amplified with OPA 07 are different from those amplified with the same primer in Figure 4.

DNA amplification by PCR

One to two hundred nanograms of DNA samples were amplified in 25 μl reaction mixtures containing 10 mM Tris HCl pH 8.3, 50 mM KCl, 0.001% gelatin, 2.4 mM $MgCl_2$, 0.03 mM each of dATP, dTTP, dGTP and dCTP, 0.64 μM random primer and 1U *Taq* DNA polymerase (Amresco and Rama Biotechnologies). A total of 23 different Indian mackerel DNA templates from three locations under study were amplified with Amresco *Taq* polymerase (hereafter referred to as *Taq* 1) while a total of 30 templates (including the earlier 23) were amplified with Rama Biotechnologies *Taq* (hereafter referred to as *Taq* 2). To test the effect of primer sequences, random selection was made from the pool of DNA samples. King seer DNA was amplified

Table 1. Percentage of templates amplified by OPA-series primers (*Taq* DNA polymerase-Amresco)

Primer	No. of individual templates tested	No. of templates amplified (at least 1 polymorphic band present)	%	Remarks

OPA 16	3	2	66.7	1-4 markers

with *Taq* 1 only. The total reaction mixture was overlaid with 25 μl of mineral oil (Sigma).

Amplification was performed in Coy II Tempcycler programmed for one initial cycle of 30 S denaturation (94°C), 30 S annealing (36°C) and 1 min extension (72°C) followed by 45 cycles of 30 S denaturation (94°C), 30 S annealing (36°C) and 2 min extension (72°C). At the end, a final extension for 7 min was performed at 72°C. Amplified products were resolved in 1.4% agarose (Sigma) gel electrophoresis in 1 × TAE. They were stained in ethidium bromide solution and under UV illumination either polaroid photographs or gel documentation pictures were taken. The RAPD bands are referred to as loci and markers interchangingly.

RAHM

RAPDs generated by OPA 07 in Indian mackerel were transferred to nylon membrane (Hybond-N, Amersham) by vacuum blotting. Thirty pmols of $(GT)_8$ (Rama Biotechnologies) were 5′ end labelled with 50 μCi of γ ^{32}PdATP. The unincorporated nucleotides were separated from the probe using Nuc Trap probe purification push column as per manufacturer's (Strategene) instructions. The purified probe had a radioactivity of 2.4×10^6 cpm. The nylon membrane containing immobilized RAPDs was prehybridized at 45°C for 3 h in a solution containing 0.1% SDS, 5 × each of SSPE and Denhardt's solution and approximately 64 μg of sonicated *E. coli* DNA. This was followed by hybridization at 45°C for 12 h in a solution containing 0.1% SDS, 5 × each of SSPE and Denhardt's solution, 64 μg of sonicated *E. coli* DNA, 1.5 g of Dextran sulphate and 120 μl of purified probe. The filter was given three final washes each for 20 min at 37°C in 3 × SSC and 0.3% SDS, dried, wrapped in cling film and developed in a phosphorimager (Molecular Dynamics Inc).

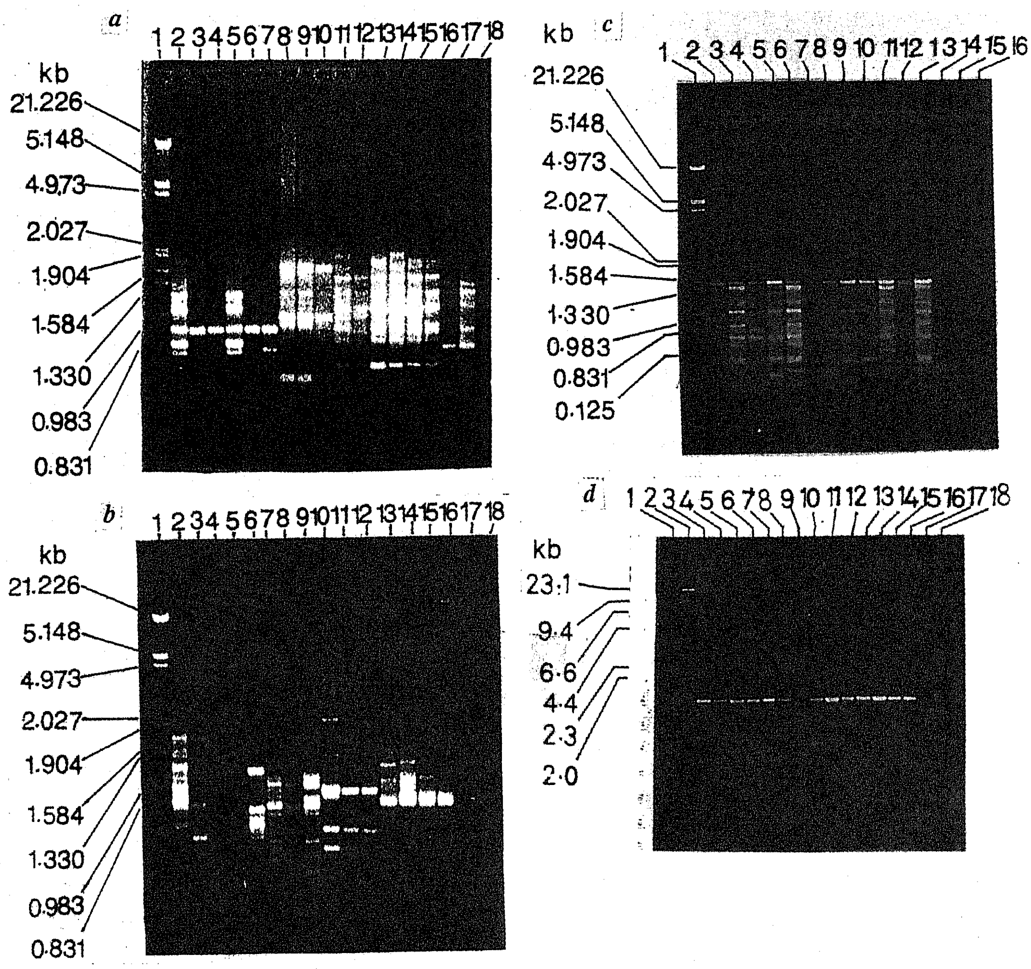

Figure 3. ***a***, RAPDs in Indian mackerel generated by OPA and OPF primers (*Taq* 1), Lane 1, λ *Hin*dIII + *Eco*RI; Lanes 2, 5, 12, 15 and 18, a specimen from Fort Kochi (OPA 18, 19, 06, 10 and OPF 04, respectively); Lanes 3, 6, 11, 14 and 17, a specimen from Mandapam (OPA 18, 19, 06, 10 OPF 04, respectively); Lanes 4 and 7, a specimen from Mangalore (OPA 18 and 19, respectively); Lanes 8–10, 13 and 16, a specimen from Mangalore (OPF 18, 19, 20, OPA 06 and 10, respectively). ***b***, RAPDs in Indian mackerel generated by OPA and OPF primers (*Taq* 1). Lane 1, λ *Hin*dIII + *Eco*RI; Lanes 2, 7, 10, 13 and 14, a specimen from Mandapam (OPF 03, OPA 09, 11, 14 and 16, respectively); Lanes 3, 5, 6, 9, 12 and 16, a specimen from Mangalore (OPF 06, 09, OPA 04, 09, 11 and 16, respectively); Lanes 4, 8, 11 and 15, a specimen from Fort Kochi (OPF 09, OPA 09, 11 and 16, respectively); Lanes 17 and 18, Blank. ***c***, RAPDs in Indian mackerel generated by OPA 07 (*Taq* 1). Lane 1, λ *Hin*dIII + *Eco*RI; Lanes 2 and 11–13, four specimens from Fort Kochi; Lanes 5, 7, 9 and 10, four specimens from Mangalore; Lanes 14–16, Blank. The individuals are different from ones whose DNAs were amplified with OPA 07 as in Figure 2 *c*, *d*. ***d***, RAPDs in Indian mackerel generated by OPA 07 (*Taq* 2). Lanes 1 and 2, λ *Hin*dIII; Lanes 3–7, five specimens from Mandapam; Lanes 8–11, four specimens from Fort Kochi; Lanes 12–16, five specimens from Mangalore. Lanes 17–18, Blank.

Results

Relatively better resolution of RAPD loci was obtained when 2.4 mM $MgCl_2$ was used (Figure 2 *a*, lane 5). With random primers from Kit G, 100 ng of genomic DNA each from king seer and Indian mackerel were amplified. While comparing lanes 6, 8, 10 and 12 with 7, 9, 11 and 13 in Figure 2 *b* it is apparent that the OPG random primers amplify DNA of king seer better than that of Indian mackerel. Further, lanes 2–13 show that difference in primer sequence would produce different RAPD patterns for the same template in both these scombroid fishes.

Considering the large number of templates tested, high percentage of amplification (amplification refers to the presence of at least one polymorphic band per gel) as well as better reproducibility, OPA 07 was found to be the ideal choice for producing RAPDs in Indian mackerel (Table 1). Figures 2 *c*, *d* and 3 *a–c* show RAPDs using *Taq* 1.

Performance of OPA 07 was even better in amplification of Indian mackerel DNA with *Taq* 2 (Table 2). Number as well as patterns of markers for the same templates generated with the same primers and two *Taq* enzymes were different. Figures 3 *d*, 4 *a–c* depict RAPD patterns using *Taq* 2.

Table 3. Percentage of templates amplified by OPF-series primers (*Taq* DNA polymerase-Amresco)

Primer	No. of individual templates tested	No. of templates amplified (at least 1 polymorphic band present)	%	Remarks
OPF 01	5	3	60.0	
OPF 02	8	2	25.0	
OPF 03	3	1	33.3	
OPF 04	3	2	66.7	One template had a single scorable band
OPF 06	3	1	33.3	
OPF 07	3	1	33.3	Bands unscorable
OPF 08	3	1	33.3	Bands unscorable
OPF 09	3	2	66.7	One template had a single scorable band
OPF 10	3	0	0	
OPF 13	3	2	66.7	One template had a single band Others had all unscorable bands
OPF 18	3	2	66.7	One template had a single scorable band
OPF 19	3	1	33.3	
OPF 20	3	1	33.3	

None of the random primers from Kit F produced loci in 100% of templates tested (Table 3). Further, the number of loci was less and reproducibility low. Figures 2 *d*, 3 *a* and *b* depict RAPD markers in different specimens of Indian mackerel sampled from Mandapam, Mangalore and Fort Kochi amplified with OPF primers.

RAHM markers of Indian mackerel are shown in Figure 4 *d*. Lanes 3, 4, 7, 8, 10 and 13 contain a total of 9 bands having complementary sequence of $(GT)_8$. This gives 25% of positive fragments after hybridization with the dinucleotide probe. Signal intensity of bands depends both on the microsatellite motifs and the abundance of the particular loci.

Discussion

RAPD could prove to be a useful tool to estimate genetic variability, relatedness, inbreeding levels, species/strain verification, pedigree analysis, detection of economic traits and in other marker-based studies in fish and shellfish. RAPDs that are diagnostic at different taxonomic levels can be generated by employing different primers and they can be used to determine the relatedness between taxa for which diagnostic RAPD fingerprints have been established[3]. However, for this PCR-based fingerprinting to provide supporting evidence for taxonomic relationships in fishes, data should be generated using adequate sample size for each species[7]. RAPD loci produced by the same random primer showed markedly different patterns between Indian mackerel and king seer in our work. Similarly, arbitrary primers of different sequences yielded different banding patterns in the same template of both scombroid fishes. This indicates utility of RAPDs by manipulation of primer sequence to generate amplification products of desired complexity to suit different purposes like genetic mapping or genotyping[7].

In a work on RAPD analysis of 12 species of fishes, there was no clear relation observed between the length of random primers and the number of fragments amplified. However, there were relatively more amplified products with primers having higher G + C content[7]. The number of products may be related to the G + C content of primers and template DNA sequence rather than to the primer length[17]. We have tested primers having G + C content 60–70% (Kit A), 50–60% (Kit F) and 50–70% (Kit G). Better performance of primers from Kit A in terms of greater percentage of templates amplified and more number of loci generated, could be attributed to their higher G + C content.

Our study clearly shows high sensitivity of RAPDs to PCR conditions. For example, the same DNA templates amplified with two different commercial brands of *Taq* DNA polymerases generated different fingerprints. This is in conformity with earlier observations[5]. Concentrations of primer and $MgCl_2$ were critical *vis-à-vis* resolution and reproducibility of RAPD loci. However, we did not find the DNA template concentration to be a decisive factor within a wide range of 1–200 ng. Total genomic DNA extracted from frozen, buffered and frozen or alcohol-preserved and frozen tissues yielded uniform results in RAPD-PCR.

Relative ease of development, low expense and potential usefulness for any kind of organism make RAPDs attractive molecular markers. However, criticisms are levelled at them for their genetic dominance (inability to differentiate homozygotes from heterozygotes), low degree of polymorphisms and exquisite sensitivity to amplification conditions. Hybridizing RAPDs with

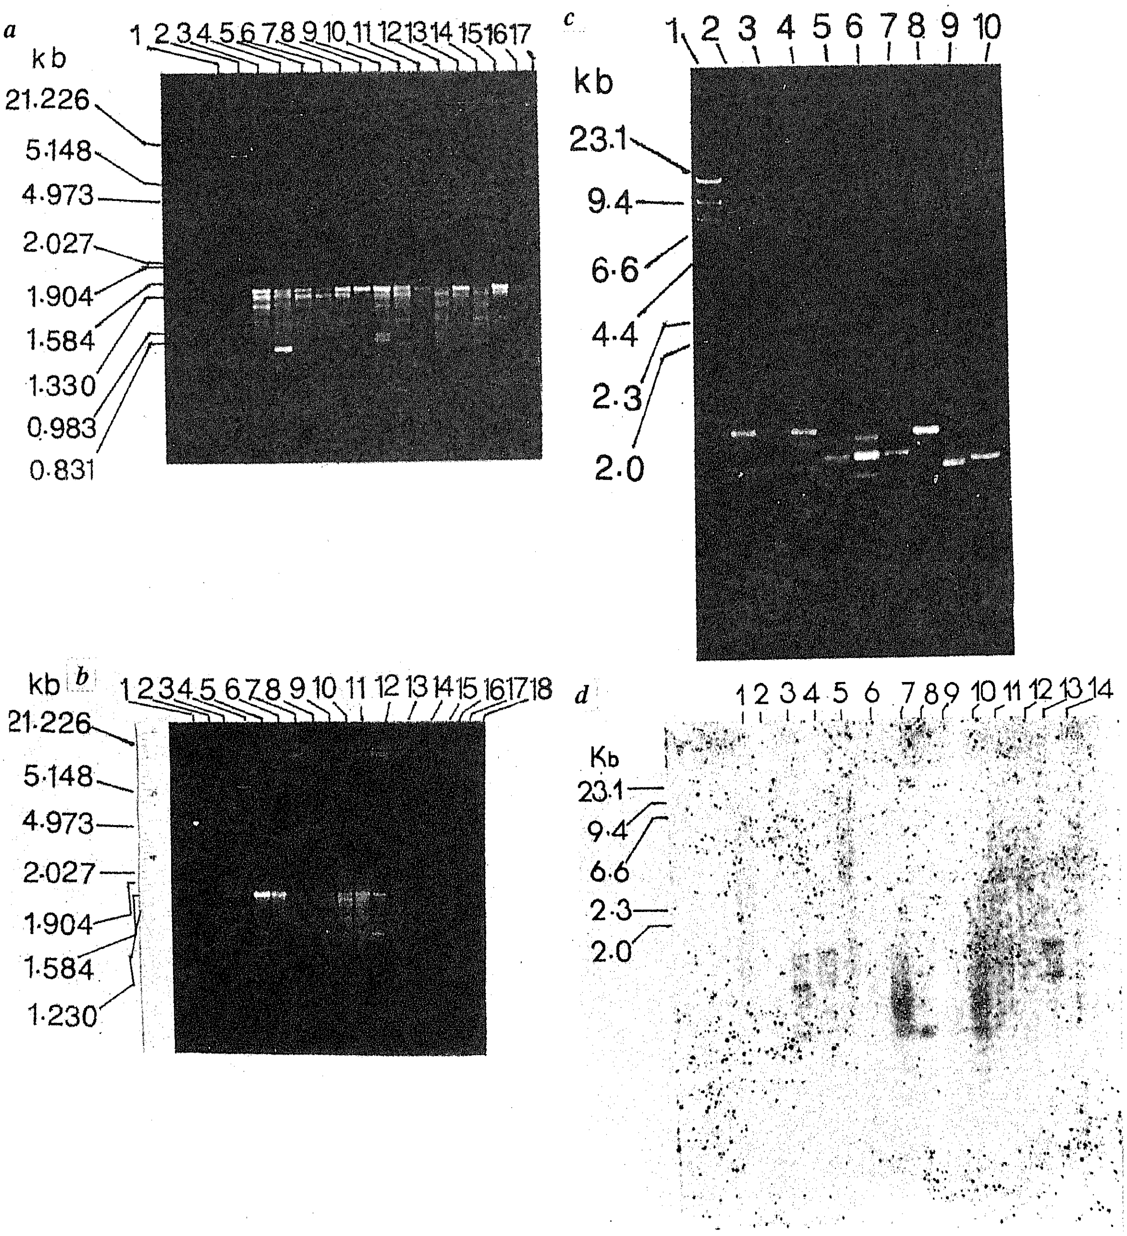

Figure 4. *a*, RAPDs in Indian mackerel generated by OPA 07 (*Taq* 2). Lanes 1, 16 and 17, Blank; Lane 2, λ *Hin*dIII; Lanes 3, 9, 10 and 15, four specimens from Mangalore; Lanes 4, 5, 8 and 11, four specimens from Fort Kochi; Lanes 6, 7 and 12–14, five specimens from Mandapam. The individual DNAs depicted here are different from those in Figure 3 *d*. *b*, RAPDs in Indian mackerel generated by OPA 07 (*Taq* 2). Lanes 1–3 and 13–18, Blank; Lane 4, λ *Hin*dIII + *Eco*RI; Lanes 5 and 12, two specimens from Mandapam, Lanes 6, 9 and 10, three specimens from Mangalore; Lanes 7, 8 and 11, three specimens from Fort Kochi. All individual DNAs depicted here are different from those in Figures 3 *d* and 4 *a*. *c*, RAPDs in Indian mackerel generated by OPA series primers (*Taq* 2). Lane 1, λ *Hin*dIII + *Eco*RI; Lanes 2–4, three specimens from Mandapam (OPA 06); Lanes 5 and 6, two specimens from Mandapam (OPA 10); Lanes 7 and 8, two Mandapam specimens (OPA 11); Lanes 9 and 10, two Mandapam specimens (OPA 16). *d*, RAPDs depicted in Figure 3*d* southern-blotted and hybridized with 5′ end labelled $(GT)_8$. RAPD loci of less than 2 kb are seen hybridized in lanes 3, 4, 7, 8, 10 and 13.

microsatellite probes can yield novel and highly reproducible fingerprinting profiles. Ethidium bromide staining can detect only the most abundant amplicons whereas majority of minor fragments may remain below the detection level to form a background smear in the gel. The ubiquitous presence of dinucleotide repeats in eukaryotic genomes provides a means of visualizing a subset of such minor amplification products by hybridization[14].

Comparing lanes 13 and 3 of Figure 4 *d* respectively with 15 and 5 of Figure 3 *d* in our paper shows generation of more number of bands when RAPDs were southern-blotted. RAHM technique can provide more information from RAPD gels and also help to reveal microsatellite genomic clones without the time-consuming screening of genomic libraries[13]. This technique offers immense potential for genome analyses in fish and shellfish.

The effects of viscosity stratification and surface tension on Rayleigh–Taylor (RT) instability in a finite thickness layer of an incompressible viscous fluid bounded above by a denser fluid and below by a rigid impermeable surface have been studied using linear stability analysis. A relation for the RT-instability growth rate is found by calculating the eigenvalues of the stability equation. It is shown that the shape of the dispersion curve is controlled by the ratio of surface tension to the stress gradient, with the layer thickness and the viscosity stratification affecting the rate of growth of the instability. The growth rate, infact, is shown to increase with increase in viscosity stratification and the thickness of the fluid layer. The results are shown to revert to those of the case of a viscous fluid layer in the absence of viscosity stratification.

THE study of instability of the interfaces is of great importance in view of its fundamental role in understanding of the control and exploitation of many of the basic physical, chemical and biological process. The interface in some of these instances occurs due to the superposition of two fluids of different densities. The instability of the interface occurring under gravity when a heavier fluid is supported by a lighter one or equivalently when a lighter fluid is accelerated towards the heavier fluid is widely known as the Rayleigh–Taylor (RT) instability[1]. These instabilities have been the subject of considerable interest in recent years mainly because of their frequent encounter in nature and in many practical applications[2,3]. They also occur in ocean tides, the accelerated interstellar clouds driven by new born stars, supernova events, sinking of slabs of tectonic plates, etc. The analysis of motion induced by the instability of the highly viscous layers in the earth's interior indeed provide rational models for the prediction of continental drifts and the volcanic activities. These instabilities are further known to occur in thin aqueous layers of biological fluids which form an integral part of the various organs and their stability plays an important role in the organ functions. In technological contexts, the RT-instabilities occur in the inertial confinement fusion (ICF) which is based on the implosion of thin deuterium (D)–tritium (T) targets driven by laser or ion beams. The target during the implosion process could be hydrodynamically unstable subject to these instabilities, which destroy the symmetry of compression of the D–T fuel preventing the high density and temperature required for thermonuclear burning with high gain in energy. These instabilities are considered responsible, in material processing applications, for grain boundary failure in metals and cracking of cross-linked polymers. The polymer failure, infact, has been shown to occur often by the formation and growth of planar defects known as crazes; both craze tip advance and craze widening are attributed to these instabilities. These instabilities are responsible for development of non-uniformities that lead to streaked and mottled layers in the growth of thin films in a variety of device fabrication applications. Thus there is evidently a considerable current interest in studying the dynamics of fluid layers from both fundamental and technological perspectives. On the fundamental level the study of layer dynamics concerns a more general problem of evolution of active and passive interfaces; the issues of interest being the formation of ordered interfacial structures and the long time asymptotic behaviour of the deformed interfaces. The understanding and controlling of the deformation of viscous layers, from the technological point of view, provides useful information for suppressing or eliminating these hydrodynamic instabilities. It is well known that various physical factors such as surface tension, viscosity, density gradients and shear rates in flowing films greatly influence the development of RT-instability. Brown[4] has recently investigated the linear instability of a highly viscous fluid layer of finite thickness and shown that such a film if stagnant would rupture as a consequence of this instability. Further, Newhouse and Pozrikidis[5] have studied the nonlinear viscous instability of a liquid layer as a function of surface tension and the ratio of viscosities of the two fluids and have shown that for moderate surface tension, the instability of the layer leads to the formation of periodic array of viscous plumes which penetrate into the overlaying fluid layers. However, the combined effect of surface tension and viscosity variation on RT-instability has not been given much attention in spite of its importance in many practical situations.

The motivation of the present study is to extend the work of Brown[4] to include the effect of viscosity stratification to know its influence on the RT-instability in a thin layer of an incompressible viscous fluid confined above by an interface with a denser fluid and below by a rigid impermeable boundary by using linear perturbation analysis. The formalism developed in the present work is primarily to elucidate the influence of the combined effects of stress gradient, surface tension, viscosity stratification and the layer thickness on the RT-instability. We found that the viscosity stratification

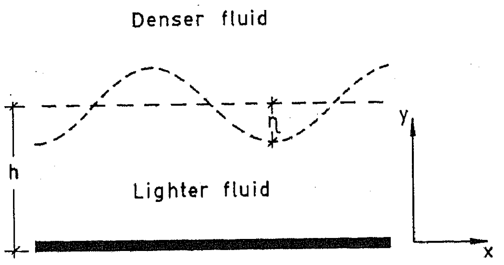

Figure 1. Physical configuration.

affects only the nature of the growth of the instability and does not change the shape of the dispersion curve.

We consider the case of two incompressible fluids with equal viscosities $\mu_F = \mu_L = \mu$ and densities ρ_L and ρ_F, where suffixes F and L refer to lower fluid (film) and upper denser fluid respectively as shown in Figure 1. The interface is characterized by surface tension γ and is governed by the layer thickness h and the interface elevation η. The flow within the viscous layer and the overlying fluid in the absence of any external force is governed by the following equations.

$$\rho\partial u_i/\partial t + \rho u_j(\partial u_i/\partial x_j) = -\partial p/\partial x_i + \partial/\partial x_j \{\mu(\partial u_i/\partial x_j + \partial u_j/\partial x_i)\} \qquad (1)$$

and

$$\partial u_j/\partial x_j = 0, \qquad (2)$$

where ρ is fluid density, u_i, u_j are velocity components, p the pressure and μ the coefficient of viscosity. The following assumptions[6] enabled us to use the creeping flow approximation:

(i) The film thickness h, is much smaller than the thickness H, of the denser fluid above the film. That is

$$h << H. \qquad (3)$$

(ii) The Strouhal number ε, which is a measure of the local acceleration to inertial acceleration in equation (1) is small. That is

$$\varepsilon = \frac{L}{TU} \ll 1 \qquad (4)$$

Here $U = \nu/L$ is the characteristic velocity, $\nu = \mu/\rho_f$ is the kinematic viscosity, $L = \sqrt{\gamma/\delta}$ is the characteristic length, $\delta = g(\rho_L - \rho_F)$, γ is the surface tension, $T = \mu\gamma/h^3\delta^2$ is the characteristic time scale. This assumption enabled us to neglect local acceleration term $(\partial u_i/\partial t)$ in eq. (2).

(iii) We consider high viscous fluid so that inertial acceleration term in eq. (2) can be neglected in comparison with viscous term.

(iv) The interface elevation η is assumed to be small compared with the film thickness h. That is,

$$\eta/h << 1. \qquad (5)$$

These assumptions enabled us to use the creeping flow approximations which allow us to neglect certain terms in the perturbation problem in order to arrive at closed form asymptotic equation for the interface evolution. In other words, we confine to the conditions of creeping flow in two dimensions and hence ignore the inertial terms. We superimpose on the basic static state of constant pressure a small symmetrical perturbation in both the velocity and pressure fields to obtain after linearizing, the following equations for the perturbed fields.

$$\frac{\partial p}{\partial x} = \mu\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right) + \frac{\partial \bar{\mu}}{\partial y}\left(\frac{\partial u}{\partial y} + \frac{\partial v}{\partial x}\right), \qquad (6)$$

$$\frac{\partial p}{\partial y} = \mu\left(\frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial x^2}\right) + 2\left(\frac{\partial \bar{\mu}}{\partial y}\right)\left(\frac{\partial v}{\partial y}\right), \qquad (7)$$

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0, \qquad (8)$$

where u and v are the velocity components in x and y directions respectively and $\bar{\mu}$ is the mean viscosity which is a function of y only. The problem of concern is the growth rate of a small periodic perturbation of the interface. We therefore assume a variation in the velocity components, pressure and the interface elevation along x-axis to be of the form

$$[u,\ v,\ p,\ \eta] = [u(y),\ v(y),\ p(y),\ \eta(y)]\ \exp(i\alpha x + nt), \qquad (9)$$

where α is the wave number and n, the growth rate. The eqs (3)–(5) in view of eq. (6) transform into the following equations

$$i\alpha p = \mu(-\alpha^2 u + \mathrm{D}^2 u) + \mathrm{D}\bar{\mu}\ (\mathrm{D}u + i\alpha v), \qquad (10)$$

$$\mathrm{D}p = \bar{\mu}(-\alpha^2 v + \mathrm{D}^2 v) + 2\mathrm{D}\bar{\mu}\mathrm{D}v, \qquad (11)$$

$$i\alpha u + \mathrm{D}v = 0, \qquad (12)$$

where $\mathrm{D} = \mathrm{d}/\mathrm{d}y$. We further consider a realistic mean viscosity stratification because it pertains to stable stratification, to be given by

$$\bar{\mu} = \mu_0 \exp(-\beta y), \qquad (13)$$

where μ_0 is a constant characterizing uniform viscosity and β the viscosity stratification factor. The elimination of pressure from eqs (10) and (11) and subsequent use of eqs (12) and (13) gives the following governing equation

$$\mathrm{D}^4 v - 2\beta\mathrm{D}^3 v - (2\alpha^2 - \beta^2)\mathrm{D}^2 v + 2\alpha^2\beta\mathrm{D}v + (\alpha^2\beta^2 + \alpha^4)v = 0. \qquad (14)$$

The foregoing equations have to be solved subject to the boundary and the interfacial conditions. The validity of the no-slip condition at the rigid boundary requires that not only normal component but also the horizontal component of velocity vanish on the bounding surface. This requirement in view of the mass conservation equation is ensured by the following conditions

$$v = \mathrm{D}v = 0 \text{ on the rigid surface at } y = 0. \tag{15}$$

The requirement of vanishing of the tangential stress at the free interface is

$$\frac{\partial u}{\partial y}+\frac{\partial v}{\partial x}=0.$$

This, using eq. (9), becomes $\mathrm{D}u + i\alpha v = 0$.

The required surface condition, from this using $u = (i/\alpha)\mathrm{D}v$ obtained from eq. (12), is

$$\mathrm{D}^2v + \alpha^2v = 0 \text{ on the interface at } y = h. \tag{16}$$

However, the normal stress at the interface is discontinuous and it is compensated by the surface tension. Therefore the normal stress is determined by the combined effects of stress gradient, surface tension and shear on the interface and is given by

$$p = -\delta\eta - \frac{\gamma\partial^2\eta}{\partial x^2} + \bar{\mu}\ \mathrm{D}v \text{ at } y = h. \tag{17}$$

Further the kinematic condition governing the interface is given by

$$\frac{\partial\eta}{\partial t}+u\frac{\partial\eta}{\partial x}+v\mathrm{D}\eta=0 \text{ at } y=h. \tag{18}$$

We consider the evolution of the interface which is described by the following interface equation

$$y = h - \eta. \tag{19}$$

The pressure balance eq. (17) in view of eq. (9) is given by

$$p = -\delta\eta + \alpha^2\gamma\eta + \bar{\mu}\mathrm{D}v. \tag{20}$$

Further, the kinematic condition expressed by eq. (18) in view of eq. (9) and the interface eq. (19) after linearizing yields

$$v = \frac{\partial\eta}{\partial t} \text{ at } y = h.$$

This using eq. (9) becomes

$$n = v/\eta. \tag{21}$$

The elimination of pressure from eqs (10) and (20) and subsequent use of eqs (10) and (18) lead to the following dispersion relation

$$n = (\alpha^2/\mu_0)v \exp(\beta h)(\delta - \alpha^2\gamma)/(2\alpha^2\mathrm{D}v - \mathrm{D}^3v).. \tag{22}$$

The growth rate n in the absence of the viscosity stratification ($\beta = 0$) may be seen to yield the result of that of the case of a fluid layer of constant viscosity considered by Brown[4]. We see that the shape of the entire dispersion curve is controlled by the ratio δ/γ, with the viscosity stratification factor β and the layer thickness h affecting only the rate of growth of the instability.

The roots λ_i (i = 1 to 4) of the characteristic equation

$$\lambda^4 - 2\beta\lambda^3 - 2(\alpha^2 - \beta)\lambda^2 + 2\alpha^2\beta^2\lambda + \alpha^2(\beta^2 + \alpha^2) = 0 \tag{23}$$

of the differential equation (14) are

$$\lambda_1, \lambda_2 = \frac{1}{2}(\beta \mp \Delta_1),\ \lambda_3, \lambda_4 = (\beta \mp \Delta_2)\ldots, \tag{24}$$

where $\Delta_1 = [\beta^2 + 4\alpha(\alpha + i\beta)]^{1/2}$, $\Delta_2 = [\beta^2 + 4\alpha\ (\alpha - i\beta)]^{1/2}$.

We see that for the entire range of values of α and β relevant to the present problem, eq. (24) provides a pair of complex and distinct roots except at $\alpha = 0$. The solution of eq. (14) in this context satisfying the boundary conditions expressed in eqs (15) and (16) may be given by

$$\begin{aligned} v = C[\{&\cos(b_1y) + A\sin(b_1y)\}\exp(a_1y) \\ &- \{\cos(b_2y) + B\sin(b_2y)\}\exp(a_2y)], \end{aligned} \tag{25}$$

where A, B and C are constants and a_i's and b_i's are the real and imaginary parts of the roots of eq. (24) and we have further, $A = A_1/A_2$ and $B = A(b_2/b_1) - (a_1 - a_2)/b_1$, where A_1 and A_2 are given by

$$\begin{aligned} A_1 = \Big[&\big\{(2a_2 - a_1)a_1 - b_1^2 + \alpha^2\big\}\cos(b_1h) \\ &+\big\{((a_2 - a_1)/b_1)(a_1^2 - b_1^2 + \alpha^2) - 2a_1b_1\big\} \\ &\sin(b_1h)\Big]\exp(a_1h) + \Big[\big\{(b_2^2 - a_2^2 - \alpha^2)\cos b_2h \\ &+2a_2b_2\sin b_2h\Big]\Big\}\exp(a_2h). \end{aligned} \tag{26}$$

$$\begin{aligned} A_2 = \Big[&\big\{b_2(b_1^2 - a_1^2 - \alpha^2)/b_1\big\}\sin(b_1h) - 2a_1b_2\cos(b_1h)\Big] \\ &\exp(a_1h) + \Big[(a_2^2 - b_2^2 + \alpha^2)\sin(b_2h) + 2a_2b_2\cos(b_2h)\Big] \\ &\exp(a_2h). \end{aligned} \tag{27}$$

We employ the perturbation wavelength given by $\lambda^* = (\gamma/\delta)^{1/2}$ and the growth rate given by $n^* = n\mu_0/(\delta\gamma)^{1/2}$ as characteristic scales associated with the problem to render the equations dimensionless for stability analysis. In view of these parameters and the eq. (25), the dimensionless dispersion relation after omitting the asterisks for simplicity is given by

$$n = [(1 - \alpha^2)/\alpha][\alpha^3Q/(2\alpha^2R - S)]\exp(\beta h), \tag{28}$$

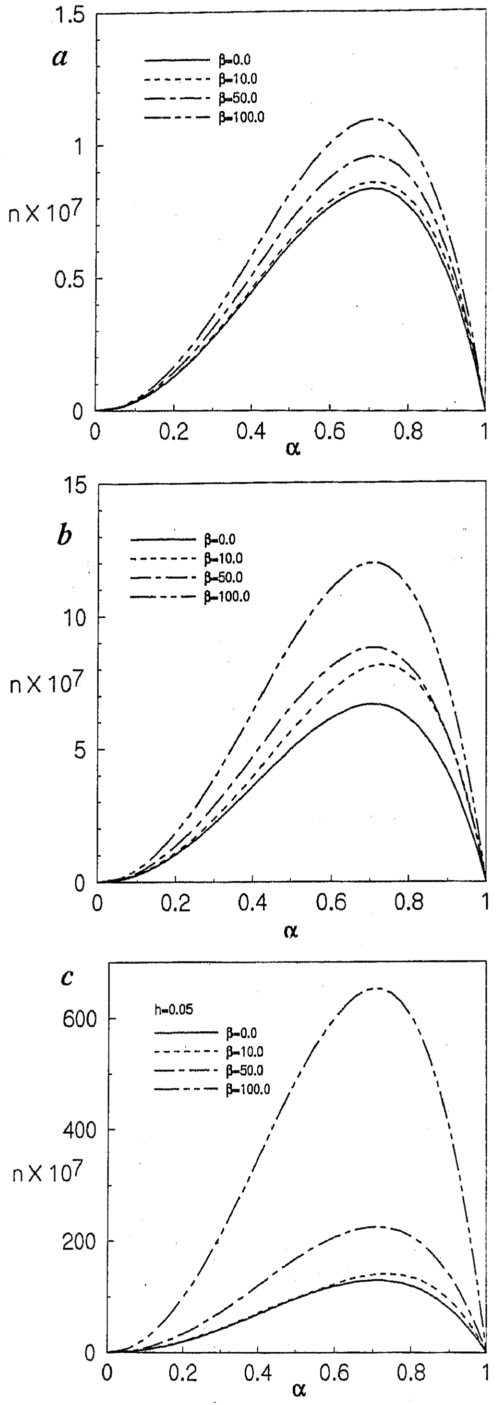

Figure 2 *a–c*. A few typical plots of the growth rate n against the wave number α.

where

$$Q = C[\{\cos(b_1h) + B\sin(b_1h)\}$$
$$\exp(a_1h) - \{\cos(b_2h) + A\sin(b_2h)\}\exp(a_2h)]. \quad (29)$$

$$R = C[\{(a_1 + Bb_1)\cos(b_1h) + (Ba_1 - b_1)\sin(b_1h)\}$$
$$\exp(a_1h) - \{(a_2 + Ab_2)\cos b_2h + (Aa_2 - b_2)$$
$$\sin(b_2h)\}\exp(a_2h)]. \quad (30)$$

$$S = C\Big[\big\{(a_1^3 - Bb_1^3 + 3a_1b_1(Ba_1 - b_1))\cos(b_1h)$$
$$+(Ba_1^3 + b_1^3 - 3a_1b_1(a_1 + Bb_1))\sin(b_1h)\big\}\exp(a_1h)$$
$$-\big\{(a_2^3 - Ab_2^3 + 3a_2b_2(Aa_2 - b_2))\cos(b_2h)$$
$$+(Aa_2^3 + b_2^3 - 3a_2b^2(a_2 + Ab_2))$$
$$\sin(b_2h)\big\}\exp(a_2h)\Big]. \quad (31)$$

A few typical plots of the growth rate n against the wave number α for a range of viscosity stratification factor β and the layer thickness h of the film are given in Figure 2.

It may be seen from Figure 2 that the whole dispersion curve is controlled by the ratio of stress gradient to surface tension, δ/γ, with the viscosity stratification factor β and the layer thickness h just affecting the nature of the growth of the instability. Eq. (28) reveals that the characteristic length L is of the order of critical wavelength and the maximum growth rate occurs at a wavelength of the same order as L. We note that our results on the growth rate in the absence of viscosity stratification ($\beta = 0$) revert to the case of Brown[4]. When $\beta \neq 0$, the frequency of oscillations of RT instability tend to amplify with increasing β in proportion to exp (βh), where the viscosity stratification $\beta = (-1/\bar{\mu})\,(\mathrm{d}\bar{\mu}/\mathrm{d}y)$ is the reciprocal of the film thickness h. This variation can readily be interpreted physically in terms of energy flux of oscillations, since it just compensates for the upward decrease of viscosity of thin film in proportion to exp $(-\beta y)$ in maintaining the flux constant. It may be observed from the plots given in Figure 2 that for given viscosity stratification factor β the RT-instability increases with increase in the layer thickness h. This behaviour of the instability growth rate may be because at higher values of the stratification factor β, the fluid viscosity $\exp(-\beta y)$ is very small at the interface and hence due to the reduced damping of the disturbance the surface becomes increasingly unstable. Initially for $\alpha < 0.7$, buoyancy dominates and every point of the interface moves faster with a velocity proportional to the elevation η of that point and elevation grows. For $\alpha > 0.7$ the surface tension action which was negligible initially becomes enhanced and elevations are reduced, the steepening process is slowed down. We note that though the values of β and h help in affecting the nature of the RT-instability growth rate, no complete change in nature of instability is possible. It is evident that although the present work is limited to the linear analysis, it throws much light on the size scale and behaviour of RT-instabilities in thin viscous layers relevant in numerous problems of natural and practical applications discussed earlier.

Mutational study and prevalence of Duchenne/Becker muscular dystrophy in different caste groups in Uttar Pradesh

S. Mishra*, V. Singh, L. S. Chaturvedi, R. D. Mittal[†] and B. Mittal

Departments of Genetics and Biochemistry[†], Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow 226 014, India
*Present address: National Biotechnology Centre, Indian Veterinary Research Institute, Izatnagar 243 122, India

Social relationships have implication on the incidence of genetic diseases in the population. To analyse this aspect in Duchenne/Becker muscular dystrophy (DMD/BMD) patients, DNA profile of the dystrophin locus was carried out by PCR and Southern hybridization. The retrospective analysis of clinical and molecular data of the patients showed higher prevalence of the disease in *brahmins* and *vaishyas* as compared to the other caste groups in this region. However, the mutational pattern is not very different in various caste groups. The results have been explained by presence of repetitive dA–dT or transposon-like sequences in the introns of the dystrophin gene.

DUCHENNE/Becker muscular dystrophies are allelic X-linked recessive genetic disorders with a frequency of 1 in 3500 live male births[1]. Duchenne type (DMD) is a severe form of the disease which causes loss of ambulation in early life, and death usually occurs by the end of the second decade. Becker type (BMD) disease follows a milder course and patients can remain ambulatory till 40–50 years of age[2].

Population-based variations in the incidence and pattern of gene mutations in DMD/BMD are well recognized. Higher prevalence of DMD has been reported in Indian migrants in UK as compared to local and other ethnic populations in that region[3]. In various European populations, gene mutations in DMD/BMD patients show nonrandom distribution which changes with linguistic boundaries of the continent[4]. We have also reported higher proportion of dystrophin gene deletions in the patients from North India[5]. Moreover, analysis of the carrier status of mothers of these patients by quantitative polymerase chain reaction has yielded very high frequency of new mutations[6]. Further, the prevailing caste-based division in Indian society provides a unique opportunity to study genetic consequences of the disease in the population. The present study depicts the retrospective analysis of molecular data related to gene mutations in DMD/BMD patients belonging to various caste groups of Uttar Pradesh.

All patients were enrolled in the out-patient department. Most of the patients came from Eastern and Central part of UP, but some were also from the north-western part of the state (Figure 1). The clinical diagnosis of DMD/BMD was based on detailed proforma which included age of onset, relative strength of muscles, Gower's sign, Pradhan's sign[7,8], degree of ambulation and levels of creatine phosphokinase (CPK) in serum. Multiplex PCR and Southern hybridization were carried according to standard methods[9]. Translational reading frame of the putative mRNA in deletional cases was determined by border type analysis[10]. Caste information was voluntarily provided by the guardians. Patients having parents/grandparents with intercaste marriages were excluded from the present analysis.

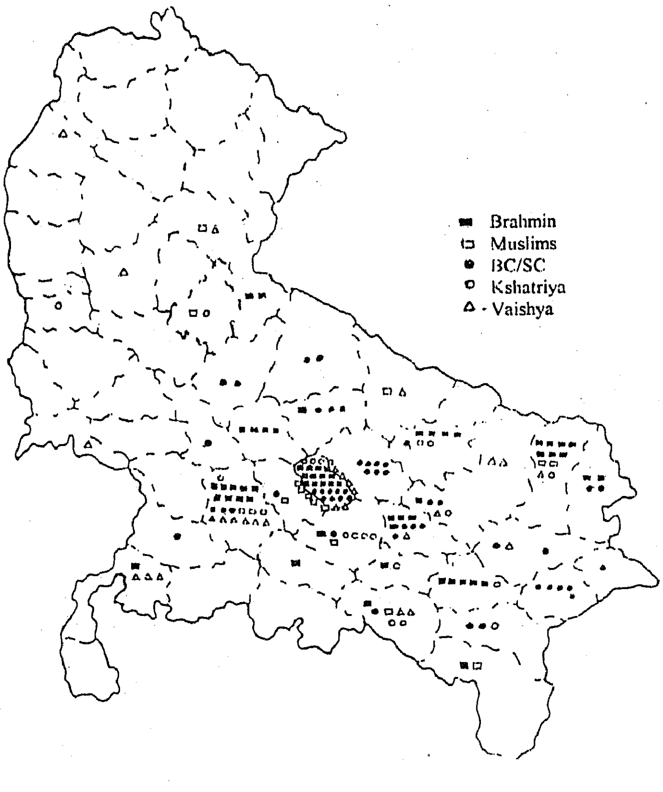

Figure 1. Regional distribution of cases of DMD/BMD among different caste groups in Uttar Pradesh.

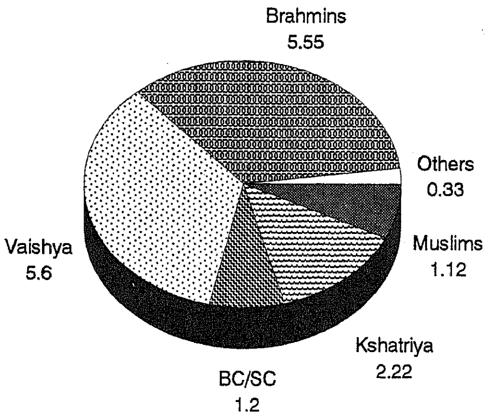

Figure 2. Comparative incidence of disease in different caste groups in UP. Relative figures are obtained by dividing number of patients with per cent population of particular caste.

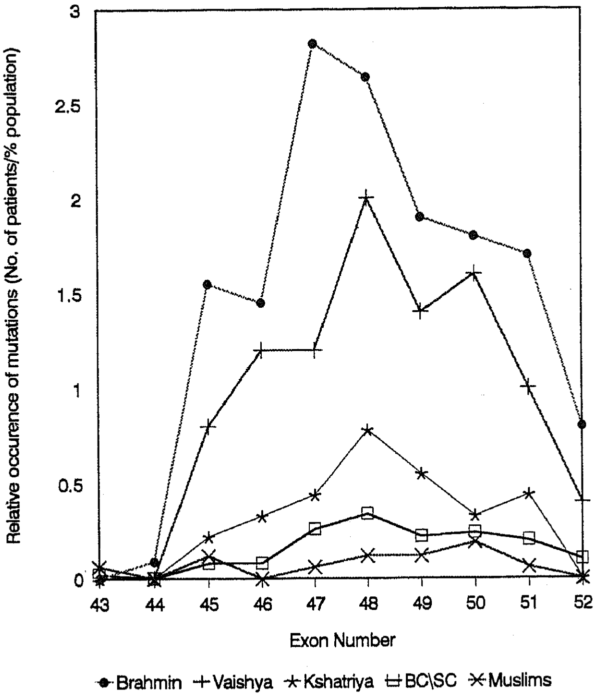

Figure 3. Relative involvement of central region exons of dystrophin gene mutations among different caste groups.

Retrospective analysis of clinical and molecular data on the basis of major caste groups of the region showed that more patients belong to *brahmins* as compared to other caste groups. Supposing that the number of patients registered in the present study is proportional to their number in general population of the region, relative incidence of disease was calculated by dividing number of patients to their percentage population in UP (based on data from *India Today*, 15 May 1996). The relative incidence of DMD/BMD was found to be much higher in *brahmins* and *vaishyas* as compared to other caste groups (Figure 2). From combined results of PCR and Southern hybridization, intragenic deletions could be detected in 70% of cases with DMD/BMD. The proportion and over-all pattern of deletions in different caste groups were similar, though minor variations in exonic involvements were observed at the central hot spot region of the gene (Figure 3).

The biology of social relation of humans is most interesting and debatable. The social structure of a community has its impact on the inheritance of genetic diseases. Communities with consanguineous marriages show higher incidence of some genetic diseases. It is impossible to plan selective breeding in human population, but in India, prevailing caste-based marriage systems provide some control over random breeding. The people generally prefer marriages in their own caste and the effect of this controlled breeding may be studied by analysing occurrence of genetic defects and polymorphism in different caste groups[11,12].

Higher relative incidence of DMD/BMD has been observed in *brahmins* and *vaishyas* as compared to other caste groups. It may be attributed to some degree of endogamous marriages followed in these caste groups. Both castes have various subgroups which prefer marriages in their own groups. Though other castes also have subgroups, the populations of *brahmins* and *vaishyas* are comparatively low in the region (*India Today*, May 15 1996), which limits their gene pool.

In DMD/BMD, about two-thirds of the patients show intragenic deletions ranging from one to several exons and the remaining one third patients are believed to have point mutations and other regulatory defects[13]. We had earlier observed relatively higher proportion of gene deletion in DMD/BMD patients from North India as compared to other populations particularly in Asia. Also, more than 80% of the mutations are clustered at the central hot spot region between exon 43 and 52 (ref. 5). This pattern holds true for all caste groups of UP despite the higher incidence of mutations responsible for causing the disease in *brahmins* and *vaishyas*. Exons(s) of the dystrophin gene involved in the patients from various caste groups are also not appreciably different (Figure 3). Moreover, no specific exon(s) deletion in the dystrophin gene could be correlated with particular caste groups analysed[14].

Molecular basis for two phenotypes resulting from mutation in the same gene has been explained by reading frame hypothesis. According to it, deletional mutations changing the translational reading frame of dystrophin should cause severe form of the disease (DMD) but deletions still maintaining the frame result in milder form (BMD)[15]. We have determined the in-frame and frame-shift deletions in various caste groups. In *brahmins*, in-frame deletions account for about 42% of their deletional cases while in others, it ranges from 14% to 23% (Table 1). However, in spite of in-frame deletions, many *brahmin* patients have severe form of the disease (DMD).

Table 1. Incidence of DMD/BMD in different caste groups of Uttar Pradesh

Caste	Population* per cent in UP	No. of affected families (patients)	Gene deletion observed in families	Gene deletion in-frame/out-frame
Brahmin	11	46 (60)	33	14/19
Kshatriya	09	19 (20)	10	2/8
Vaishya	05	21 (28)	13	3/10
BC/SC	50	51 (60)	26	5/21
Muslims	16	17 (18)	07	1/6
Others	09	02 (03)	00	0/0

*% Population of different castes was obtained from *India Today*, 15 May 1996.

Various factors have been attributed for population-based variations in the dystrophin gene mutations. Presence of repetitive elements like d*A*–d*T* stretches and transposon-like sequences have been implicated in the high frequency of deletional mutations at the central hot spot region of the dystrophin gene[16,17]. It is possible that due to phenomena like genetic drift, local DNA environment might be different in various caste groups. Such differences can probably account for variations in occurrence of pathogenic mutations at the DMD locus. It would be of interest to further explore specific haplotypes for Xp^{21} locus (location of dystrophin gene) in different caste groups. These observations may have implications for genetic counselling programmes in our country.

Studies on antianaphylactic activity of fractions of *Albizzia lebbeck*

C. C. Barua, P. P. Gupta, G. K. Patnaik, D. K. Kulshrestha and B. N. Dhawan

ICMR Centre for Advanced Studies for Traditional Remedies, Division of Pharmacology, Central Drug Research Institute, Lucknow 226 001, India

Two fractions (F079 and F080) of the hot aqueous extract of stem bark of *Albizzia lebbeck* have been evaluated for antianaphylactic/antiallergic activity *in vitro* and *in vivo*. Both fractions inhibited antigen-induced contraction of the sensitized guinea pig ileum (Schultz–Dale phenomenon). The bronchoconstriction induced by the antigen egg albumin in presensitized guinea pig was also inhibited by these fractions in a dose-dependent manner. The fractions, however, did not possess any bronchodilatory effect *per se* in nonsensitized animals.

THE treatment of bronchial asthma is far from satisfactory. A potent drug against bronchial asthma is still wanting. However, there are claims in the traditional systems of medicine for the treatment of bronchial asthma. *Albizzia lebbeck* is a major constituent of the traditional medicines used against bronchial asthma[1]. The decoction of the bark of *A. lebbeck* was found to protect guinea pigs against antigen-induced challenge and there was a marked inhibition of Schultz–Dale phenomenon[2]. Chronic treatment with the bark decoction also protected the sensitized guinea pigs against antigen challenge[3]. It has been observed that the aqueous extract of the plant possesses antiallergic activity. In a previous study we have observed that the hot aqueous extract of the plant showed promising antiallergic activity in PCA (passive cutaneous anaphylaxis) and mast cell stabilizing activity[4]. The most active fraction from this extract was further chromatographed and fractions F079 and F080 showed maximum activity. The antiasthmatic/

antiallergic activities of these fractions cannot be wholly due to smooth muscle relaxant, antihistaminic or antispasmodic activity[2]. To validate the traditional use of the plant, the present study deals with the effect of these fractions on Schultz–Dale phenomenon, egg albumin-induced bronchoconstriction and bronchodilatory activity *per se* (Konzett and Rossler experiment).

The present study was conducted with the aqueous decoction of the stem bark of *A. lebbeck.* Coarsely powdered bark of the tree (1 kg) was heated with water (2 l) over a boiling water bath for 4 h. The aqueous extract was collected by decantation. The process was repeated four times. The combined extract was evaporated to dryness under vacuum at 70°C, leaving a residue (150 g). The dried extract was not fully soluble in water and did not show any clean spots on thin layer chromatogram. A portion of the dried extract (5 g) was macerated with water (4 × 10 ml) and the insoluble residue (1.5 g) was filtered off. The soluble portion was concentrated and charged on a column of XAD – 2 resin (20 g). Elution was carried out successively with water, 20% aq. methanol, 40% aq. methanol, 60% aq. methanol, 80% aq. methanol and methanol, 100 ml each. Eluates of water, 20% aq. methanol, and 40% aq. methanol were combined together to give a water-soluble fraction F079, whereas the eluates of 60% aq. methanol, 80% aq. methanol and methanol were combined together to give a methanol-soluble fraction F080.

Male guinea pigs (350–450 g) were sensitized with egg albumin (EA 10 mg/kg i.p.) on day 1 and 3. On the day 14, animals were sacrificed and ileal strips from each animal were mounted in isolated organ bath using Tyrode's solution at 37 ± 0.5°C. Tissue sensitivity was tested with histamine hydrochloride (0.05 μg/ml). Antigen was added to the 30 ml bath (EA 3 μg/ml) and responses recorded for 90 s. Various concentrations of *A. lebbeck* fractions (F079/F080) were added to see the inhibition or potentiation of antigen-induced concentration of ileal strips. IC_{50} (inhibitory concentration) were calculated.

Male guinea pigs (350–450 g) were sensitized with antigen on day 1, 3 and 5 (EA, 100 mg i.m.). After 4 weeks, the animals were transferred to the aerosol chamber and a fine mist of the antigen (EA 5%) was sprayed into the chamber under a constant pressure (280 mmHg) till the preconvulsive breathing started. The time was noted down. *A. lebbeck* (F079/F080) fractions were administered orally (50 mg/kg) and disodium cromoglycate (50 mg/kg i.p.) 1 h prior to challenge and the time for showing preconvulsive breathing was recorded. Per cent protection from anoxic convulsion was

Fraction	Conc. (μg/ml)	Per cent inhibition of contraction (Mean ± SD)
F079	1.5	24.5 ± 5.19
	2.0	41.85 ± 8.17
	2.5	71.9 ± 7.67
F080	1.0	25.16 ± 5.10
	1.5	61.36 ± 3.27
	2.0	79.66 ± 1.52

Table 2. Per cent protection from egg albumin induced anoxic convulsion by *A. lebbeck* ($n = 3$)

Fraction	Dose (mg/kg p.o.)	Per cent protection from anoxic convulsion
F079	50	62.69 ± 1.99*
F080	50	46.86 ± 1.95*
DSCG	50 (i.p.)	68.33 ± 3.21*

*Significant activity ($p < 0.05$).

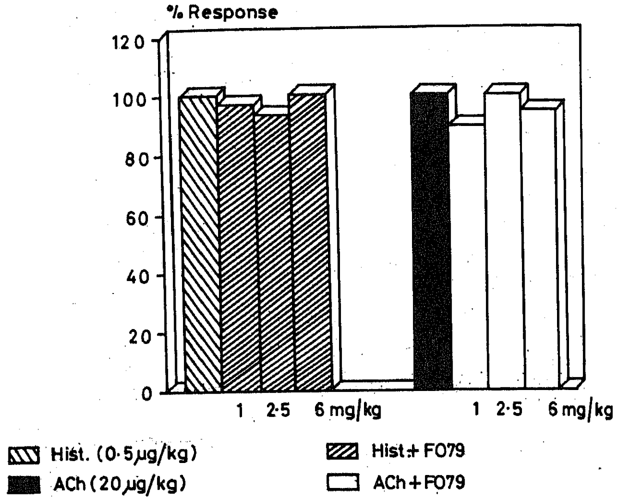

Figure 1. Effect of *A. lebbeck* fraction F079 on bronchoconstriction in guinea pig Konzett–Rossler preparation (Not significant); $n = 3$.

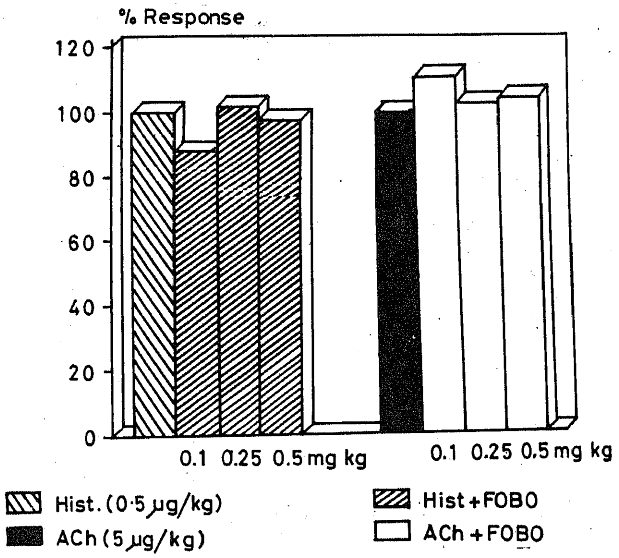

Figure 2. Effect of *A. lebbeck* fraction F080 on bronchoconstriction in guinea pig Konzett–Rossler preparation; $n = 3$.

calculated by the formula $(1 - T_1/T_2 \times 100)$ where T_1 is the mean of preconvulsion time 2 days before treatment and T_2 is the mean of preconvulsion time 2 days after the treatment[5].

In Konzett preparation, normal male guinea pigs (350–450 g) were used. They were anaesthetized with urethane (0.6 ml/100 g, 25% solution) and tied on the operating table. The trachea was cannulated and constant volume of air (6–10 cc) from the respirator was passed through the tracheal cannula[6]. The bronchoconstriction was induced by histamine (0.5 µg/kg) or acetylcholine (20 µg/kg). Thereafter, varying concentrations (0.1 to 5 mg/kg) of *A. lebbeck* (F079/F080) were injected intravenously to see the effect on spasmogen-induced bronchoconstriction.

Statistical analysis was done using Student's *t* test. The effect of *A. lebbeck* on Schultz–Dale phenomenon in guinea pig is summarized in Table 1. It was seen that *A. lebbeck* treatment significantly inhibited antigen-induced contraction in a dose-dependent manner while the response to histamine was maintained. IC_{50} (inhibitory concentration) was also calculated, which was 2.2 and 1.3 µg/ml with F079 and F080 respectively.

When *A. lebbeck*-treated presensitized guinea pigs were exposed to antigen in the aerosol chamber, there was a significant protection from anoxic convulsion. The results are summarized in Table 2. The fraction F079 showed 62 per cent protection which is comparable to the standard drug disodium cromoglycate, whereas with the fraction F080, it was not very significant.

In the Konzett preparation, *A. lebbeck* fractions (F079/F080) did not produce any inhibition or potentiation of histamine-induced bronchospasm. Fraction F079 (0.5, 2.5 and 5 mg/kg) and fraction F080 (0.1, 0.2 and 0.5 mg/kg) did not antagonize histamine and acetylcholine-induced bronchospasm (Figures 1 and 2).

The beneficial effect of *A. lebbeck* bark in bronchial asthma is not due to any significant bronchial smooth muscle activity[3]. In the studies from our laboratory on the mast cells of albino rats, it was found that it has cromoglycate-like action, inhibiting degranulation of sensitized mast cells when exposed to the antigen. In studies on the Schultz–Dale reaction in guinea pigs, there was dose-dependent inhibition of antigen-induced contraction of sensitized ileum treated with *A. lebbeck*. This effect could be due to stabilization of guinea pig intestinal mast cell membrane, inhibiting antigen-induced histamine release or due to inhibition of phenomenon of sensitization[7]. In the peritoneal mast cells of sensitized albino rats treated with *A. lebbeck*, there is inhibition of degranulation when exposed to antigen *in vitro*[2]. Thus *A. lebbeck* has the mast cell-stabilizing activity. This may be responsible for inhibition of the release of mediators in Schultz–Dale reaction in guinea pigs also.

Similarly, when the sensitized guinea pigs were exposed to the antigen spray in the aerosol chamber, there was either prevention of anaphylaxis or prolongation of the latent period of preconvulsive breathing. The protection from preconvulsion is comparable to the standard drug disodium cromoglycate. In previous studies when normal animals were exposed to the histamine aerosol[2], neither the fractions nor the standard drug could protect the animals from anoxic convulsion. These results indicate that *A. lebbeck* protects the sensitized guinea pigs from anoxic convulsions in a manner similar to disodium cromoglycate.

In the Konzett Rossler preparation, the plant fraction does not protect the normal guinea pigs from histamine and acetylcholine-induced bronchospasm even in high doses.

Thus, the present study shows that *A. lebbeck* fractions can protect the sensitized guinea pigs against antigen-induced bronchospasm, inhibit Schultz–Dale phenomenon of guinea pigs, but are devoid of any bronchodilatory activity. The fractions, therefore, contain the active constituents responsible for antiasthmatic activity of the plant. Further study is in progress to isolate and characterize the active principle(s) and to establish their mode of action.

Effect of supplementary ultraviolet-B radiation on young wheat seedlings

Prabhat Kumar Sharma*, **Rajendra Shetye** and **Saroj Bhonsle**[†]

Department of Botany and [†]Department of Microbiology, Goa University, Goa 403 205, India
*Present address: Department of Biochemistry and Physiology, IACR-Rothamsted, Harpenden, Herts AL5 2JQ, UK

Effect of supplementary UV-B radiation (1 mW m^{-2}) on photosynthesis, flavonoid content and anatomical changes was studied in young wheat leaves. It was observed that supplementary UV-B radiation did not affect PS II activity, assayed as water to phenylenediamine. However, PS I activity, assayed as reduced dichlorophenol indophenol to methyl viologen, showed an increase. UV-B treatment resulted in qualitative and quantitative changes in UV-B absorbing phenolic compounds. Flavonol (Kaempferol) and caumarin showed quantitative increase due to supplementary UV-B exposure to the wheat leaves. Synthesis of cinnamic acid was observed only after 4 days of UV-B treatment. UV-B treatment resulted in significant anatomical changes in the leaves. There was a massive increase in the cutin synthesis. Epidermal cells were largely destroyed, while hypodermal cells were seen to replace the epidermal cells.

HIGH fluence rate of short wavelength (<320 nm) reaching the earth is increasing due to ongoing depletion of stratospheric ozone layer[1]. Plants use sunlight for photosynthesis and as a consequence are exposed to the ultraviolet radiation. The enhanced levels of UV-B radiation induce damage to various plant processes, particularly resulting in lowered photosynthesis and inhibited growth[2]. A large number of plants exhibit UV-B response, but the photoreceptor responsible for important biochemical parameters such as photosynthesis remains to be conclusively identified[3–6]. The damages due to UV-B radiation can be classified into two categories: damage to DNA (it can cause heritable mutations) and damage to physiological processes such as photosynthesis and proteins, subsequently resulting in decline in plant productivity[7].

To protect itself against enhanced UV radiation, plants have developed protective responses which may prevent damage to the various physiological processes. UV-B-absorbing phenolic compounds (flavonoids) are thought to protect photosynthetic tissue by acting as screening pigments[8,9]. Besides, anatomical changes may occur to reduce the level of UV-B reaching the susceptible site(s).

In this study, we report the effect of UV-B radiation on photosynthesis (PS II activity), qualitative and quantitative changes in UV-B absorbing compounds (flavonoids and other phenolic compounds) and anatomical changes that were observed in wheat leaves in response to UV-B treatment.

Wheat (*Triticum aestivum* L. cv. HD 2380) seeds from Indian Agricultural Research Institute, New Delhi, were grown in 10 cm × 10 cm plastic pots containing vermiculite, and bottom-irrigated routinely using 1/2 strength Hoagland's solution. Plants were grown in a growth chamber illuminated with incandescent bulbs and fluorescent tubes for 12 h photoperiod having a photon flux density (PFD) of 200 μmol m^{-2}s^{-1}, measured with a radiometer (model LI-189, Licor, USA). The day/night temperature was maintained at 25 ± 2°C.

Pots containing 4-day-old wheat seedlings were transferred to another growth chamber with identical PFD, photoperiod and temperature described under growth conditions and were supplemented with UV-B radiation. The source of UV-B was a Vilbour-Lourmat (France) T-6 M source (1 × 6 W fluorescent tube with a permanent filter) with a peak at 312 nm (Figure 1). The UV-B radiation was measured using a UV-B radiometer (with a sensor for 312 nm) from the same manufacturer (Vilbour-Lourmat). The intensity of UV-B irradiation was measured at base, middle and top of the seedlings by placing the sensor of the UV-B radiometer in close contact with the leaves in the middle of the pot. The average intensity of UV-B radiation was 1 mW m^{-2}. Care was taken to maintain the average level of UV-B irradiance at 1 mW m^{-2} during the treatment while plants were growing by changing the distance between source and seedlings and placing the bandage cloth in between.

Isolation of chloroplast from control and treated wheat seedlings and PS II activity (assayed as H_2O to phenylenediamine; O_2 evolution) and PS I activity (assayed as $DCIPH_2$ to MV; O_2 uptake) were assayed according to Sharma and Singhal[10].

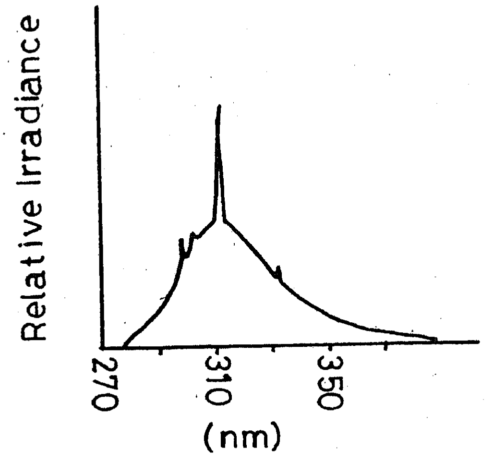

Figure 1. Spectral curve of UV-B source. Filter life time unlimited. Source intensity 6 mW cm^{-2}.

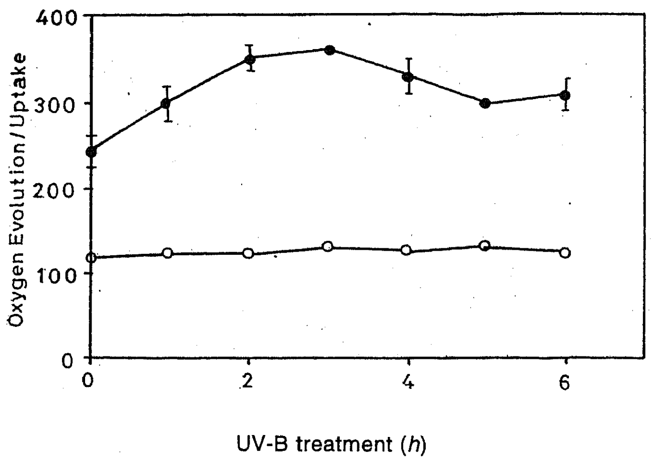

Figure 2. Effect of UV-B radiation (1 mW m^{-2}) on PS II (–O–) assayed as H_2O to phenylenediamine (oxygen evolution) and PS I activity (–●–) assayed as reduced dichlorophenol indophenol to methyl viologen (oxygen uptake). The PPFD during assays was 1200 μmol m^{-2} s^{-1}. Rates are expressed as μmol O_2 evolved or consumed/mg chlorophyll/hour. Each point represents a mean value of 4 experiments. Standard error (±8) for PS II is not visible on the scale.

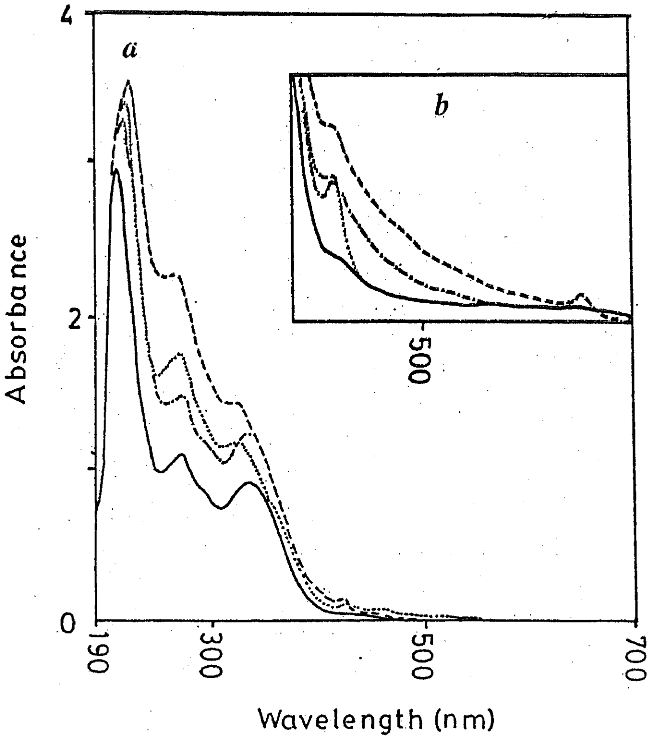

Figure 3. Effect of supplementary UV-B radiation on quantitative change in flavonoid contents in wheat seedlings. *a*, Spectral scan at 1:5 dilution; *b*, Spectral scan at 1:3 dilution. Control, i.e. 0 day UV-B treatment (------), 3 day UV-B treatment (.........), 5 day UV-B treatment (–.–.–.–.–.–) and 7 day UV-B treatment (————).

Fresh leaves (2 g) were excised and homogenized in 20 ml of 80% methanol with 1% HCl (final volume) in a mortar. The homogenate was incubated for 2 h at room temperature in the dark and centrifuged at 1600 *g* for 20 min. The supernatant was collected for absorption spectra, paper chromatography and HPLC (Spectraphysics).

Spectral scan of UV-B absorbing compound was carried out with diluted extract using spectrophotometer (Shimadzu UV240).

For paper and HPLC analysis, 5 ml of each sample was fully dried by flushing N_2 and re-dissolved in 200 μl of methanol. 20 μl of sample was loaded on a Whatman filter paper no. 1 and resolved using *n*-butanol:acetic acid:water (6:1:2) at room temperature and observed under UV photoilluminator.

Identification and separation of flavonoids was carried out using HPLC (Spectraphysics) with a C18 reverse-phase column (ET 250/4 Nucleosil 100-5C_{18} ODS) Spectraphysics SP 8800 ternary HPLC pump with SP 4270 integrator and Spectra 100 variable wavelength detector. The 100 μl of re-dissolved sample was diluted in 1 ml methanol and 25 μl of this was injected into the HPLC column. The separation was carried out using an isocratic system (0.5% phosphoric acid and methanol in 1:1 ratio) over 20 min with a 1.0 ml/min flow rate at 280 nm and 418 nm at room temperature.

Wheat leaves were fixed in a solution containing 50% alcohol, 10% acetic acid and 10% formic acid. The fixed material was passed through a series of 90, 70, 50, 30 and 100% of alcohol for 2 h to overnight duration. This was followed by a series (50, 70, 85, 95 and 100%) of tertiary butyl alcohol (TBA) for 2 h duration followed by TBA and paraffin oil (1:1) for 2 h. The plant material was then fixed in paraffin wax (60°C) blocks and cut into sections using microtome (Sipcon SP1110). Sections were stained with safranine and fast green and mounted in the DPX. The anatomical observations were recorded by light microscope (Leica) with photographic attachment (Leica).

It was observed that plants treated with supplementary UV-B radiation did not result in significant changes in the PS II activity, assayed as H_2O to phenylenediamine (PD), compared to the plants grown without supplementary UV-B radiation (0 h). However, PS I activity assayed as dichlorophenol indophenol ($DCIPH_2$) to methyl viologen (MV), showed a significant increase in the activity in UV-B supplemented plants compared to non-supplemented plants (Figure 2).

Absorption spectra of 80% methanolic extract with 1% HCl is shown in Figure 3 *a*. It was observed that plants treated with UV-B radiation showed an increase in the absorption peaks at 210–220 (caumarin). UV-B treated plants showed a slight shift in the absorption peak of caumarin from 210 to 220 nm, 270–280 nm (Kaempferol) and 320–330 nm (flavone). Absorption spectra of concentrated extract also showed slight changes in the absorption at 418 and 660 nm (anthocyanin) in the visual region (Figure 3 *b*, Table 1).

UV-B-absorbing compounds showed qualitative changes in response to UV-B radiation which were

Table 1. Effect of supplementary UV-B radiation (1 Mw m^{-2}) in combination with visual radiation (60 μmol m^{-2} s^{-1}) at 25°C on flavonoids and its derivatives in wheat seedlings. Comparative data of spectrophotometric analysis and paper chromatogram seen under visual and UV-B transilluminator before and after NH_3 fuming. According to Swain[11] the colour of spot under visible and UV light with and without NH_3 treatment of the chromatogram indicate type of flavonoid

Spectrophotometric data		Paper chromatogram					
			Spot colour				
					+NH_3 fumes		
Lamda max	Compound	*Rf* × 100	Visible	UV	Visible	UV	Compound
270	Flavonol (Kaempferol)	84	Brownish yellow	Brownish yellow	Brownish yellow	Brownish yellow	Flavonol
210	Caumarin	79	Colourless	Blue	Colourless	Blue	Caumarin
		59	Colourless	Lightblue arrowshape	Colourless	Light blue arrowshape	Cinnamic acid
418	Anthocyanin	56	Brownish yellow	Brownish yellow	Brownish yellow	Brownish yellow	Anthocyanin
320–330	Flavone	34	Colourless	Purplish brown	Yellow	Yellow	Flavone
655–660	Anthocyanin	31	Brown	Purplish brown	Bright yellow	Bright yellow	Anthocyanin

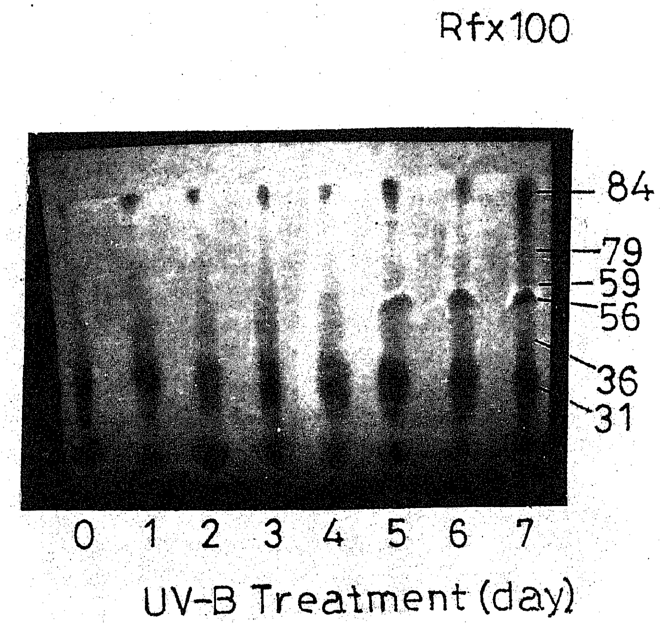

Figure 4. Effect of supplementary UV-B radiation for 0 to 7 day (left to right in the figure) on flavonoid content in wheat seedlings. The *Rf* value and colour composition under visual light with and without NH_3 fumes and nature of compounds are given in Table 1.

determined by paper chromatography. All major compounds visualized in extract from UV-B-irradiated plants were seen in control except cinnamic acid which appeared after day 4 of UV-B treatment (Figure 4). The possible group of flavonoids were determined on the basis of *Rf* value, and colour characteristics under visual and UV transilluminator (with and without treatment with NH_3 fumes) and their absorption spectra according to Swain[11] (Table 1).

HPLC analaysis of methenolic extract at 280 nm showed qualitative changes in the flavonoids. UV-B exposure resulted in an appearance of two new peaks (peak no. 3 and 7; cinnamic acid and anthocyanin respectively) compared to the control. Peaks 1 and 2 (kaempferol and caumarin respectively) showed increase due to the supplementary UV-B exposure. HPLC analysis using visual range (418 nm) also showed significant changes in the anthocyanin (Figure 5 *b*). The nature of new peaks observed in Figure 5 *b* could not be determined.

The leaf section showed a massive increase in the deposition of cuticle wax in the UV-B treated leaves compared to control (Figure 6 *a–d*). Epidermis was damaged to a greater extent (Figure 6 *b* and *c*). Mesophyll cells were converted into hypodermal cells (Figure 6 *c*) to replace the damaged epidermal cells (Figure 6 *c* and *d*).

Our study shows that supplementary UV-B radiation did not cause significant changes in the PS II activity but the PS I activity showed a significant increase. Qualitative and quantitative changes in the flavonoids and other phenolic (phenyl propane) derivatives using analytical techniques such as spectrophotometry and chromatography were also observed.

Response of photosynthetic apparatus to UV-B radiation has been studied by several workers[9,12–16]. A few reports have suggested photosystem II as the UV-B-sensitive component[14,15], but the action spectrum of UV-B does not suggest a specific target molecule[5,6,13].

Jie He *et al.*[15] observed decrease in PS II activity measured as *Fv*/*Fm* ratio in rice and pea leaves. However, they have not measured photosynthetic electron

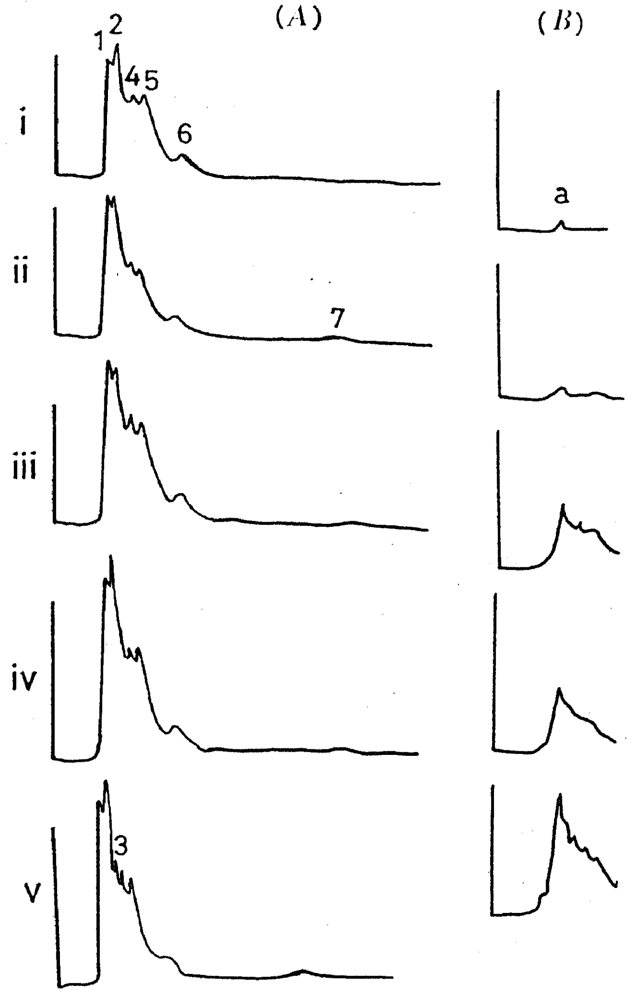

Figure 5. HPLC analysis showing qualitative and quantitative changes in wheat seedlings under supplementary UV-B exposure for 0 (i), 2 (ii) 3, (iii) 5 (iv) and 7 (v) days. ***A***, HPLC analysis at 280 nm. 1, Kaempferol; 2, Caumarin; 3, Cinnamic acid; 4 and 5, Flavone; 6 and 7, Anthocyanin; ***B***, HPLC analysis at 418 nm. *a*, anthocyanin. Other peaks seen are not identified.

transport. Middleton and Teramura[9] showed that the reduction in photosynthesis, under UV-B radiation, was primarily associated with a stomatal limitation rather than the damage to PS II.

In our study we have not observed any damage to PS II activity (Figure 2). This may be due to low UV-B fluence rate (1 mW) for a short duration (up to 6 h only). Also, the effect of supplementary visual radiation ($200\ \mu\mathrm{mol\ m^{-2}\ s^{-1}}$) during the UV-B exposure, may have resulted in preventing the damage due to PS II. There have been reports that UV-B-mediated effects are dampened by the background intensities of photosynthetic active radiation[17–20].

The increase in the PS I activity may be owing to micro-environmental changes in the thylakoid membrane (lipids/protein) due to oxidative damage[21], making reduced DCIP more assessable to the site of action (electron donation).

In this study we observed quantitative and qualitative changes in the UV-B absorbing flavonoids in response to supplementary UV-B radiation (Figures 3–5). It has been suggested that flavonoids and phenyl derivatives are involved in the protection against UV-B exposure in higher plants[8,12,15,22,23]. Flavonoids and anthocyanins absorb UV-B radiation and these generally accumulate in the epidermis. Here they could keep UV-B radiation from reaching photosynthetic tissues and other sensitive sites (protein, DNA, etc.).

Lois[8] observed that irradiance of *Arabidopsis* with UV-B light resulted in accumulation of flavonoids in the aerial parts of the plants. He correlated this increase with the protection (less damage to plant growth) against UV-B damage.

Lois and Buchanan, working with *Arabidopsis* mutant deficient in flavonoids accumulation, found that mutant displayed a dramatic increase in the sensitivity (reduced plant growth) to UV-B radiation compared with wild type, suggesting a protection role for flavonoids against UV-B radiation.

Li *et al.*[16], working with *Arabidopsis* mutant with defects in the synthesis of flavonoids, found them more sensitive (less dry weight) to UV-B than the wild type when grown under UV-B radiation.

Jie He *et al.*[15], working with rice and pea plants, found that rice cultivar showed less decrease in *Fv/Fm* ratio as compared to pea. They correlated this to the higher levels of UV-B absorbing compounds in rice as compared to pea. This indicates a role of flavonoids in the protection against UV-B in higher plants.

In this study we also observed a slight shift in the absorption peak of caumarin (210–220 nm; Figure 3 *a*). This shift in lambda maximum for caumarin may be due to its glycosylation[23].

Our study shows massive increase in the cuticle layer in the leaves in response to UV-B radiation (Figure 6 *a*–*d*). Earlier studies have shown that UV-B radiation causes epidermal deformation[12], changes in cuticular wax composition[24]. These changes may result in preventing harmful UV-B radiation to reach sensitive site. Hahlbroack and Scheel[25] and Robberecht and Caldwell[26] reported that cutin deposition along with flavonoid synthesis in upper epidermis could block transmittance of 95–99% of incoming UV-B radiation.

The increase in the cuticle layer under UV-B exposure may prevent the penetration of the UV-B radiation by reflecting large amounts of it. Development of hypodermal cells from mesophyll cells (Figure 6 *c* and *d*) may replace the damaged epidermis. Also the development of hypodermal cell may prevent the UV-B radiation from reaching the more sensitive sites by providing layer(s) of cells which accumulate large amounts of

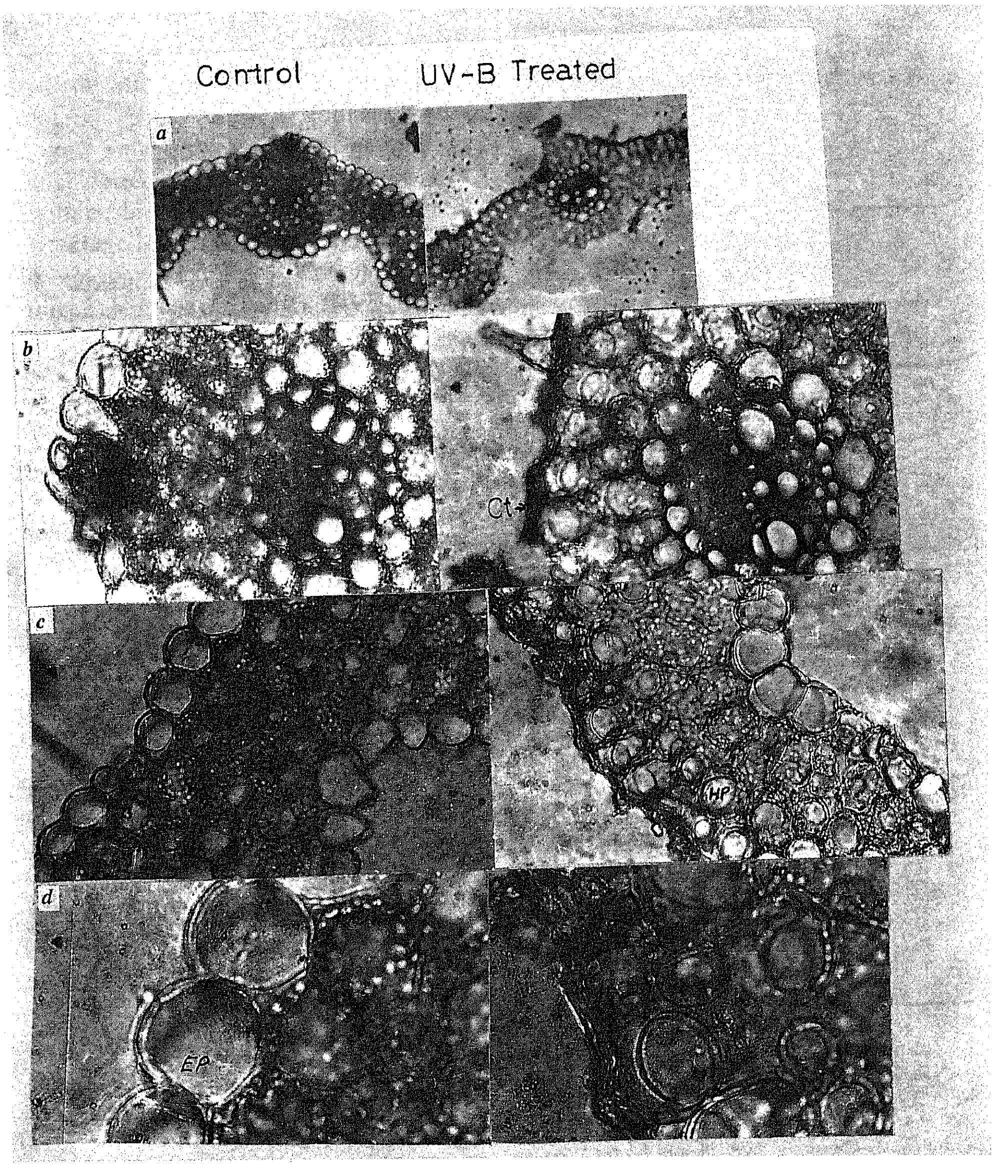

Figure 6. Effect of supplementary UV-B radiation on leaf anatomy. ***a***, TS of mid rib portion of control and UV-B treated leaf respectively (10×); ***b***, TS of mid rib portion of control and UV-B treated leaf respectively (40×). EP, Epidermal cell.

phenolic compounds (flavonoids). This may further help in absorbing the UV-B radiation, thus protecting more sensitive sites, such as DNA and enzymes, from UV-B radiation.

Temporal patterns of visitation among avian frugivores at fruiting strangler figs in a tropical evergreen forest in the Western Ghats, Southern India

Vidya R. Athreya

National Centre for Radio Astrophysics, Post Bag 3, Pune University Campus, Pune 411 007, India

Frugivory observations were conducted at fruiting strangler figs in Karian Shola National Park in the Anaimalai hills from January to March 1993. A total of 123 hours of fruit use by frugivores was observed at fruiting trees of four species of *Ficus*. Frugivore activity was seen throughout the day with a major peak in visitation between 7.00 AM and 9.30 AM and a minor one at 2.30 PM. The common frugivore species exhibited preferences for different species of fruiting strangler figs, occurring in larger numbers at these trees. Of the seven common species of avian frugivores, only two pairs exhibited similar temporal patterns of visitation to the fruiting strangler figs, the Small Green Barbet–Crimsonthroated Barbet pair at *F. drupacea* and bulbul spp.–Golden Oriole pair at *F. microcarpa*. The pressures of competition, past or contemporary may be the reason behind the difference in the temporal pattern of visitation. However, it is unlikely that active competition is the cause since very few inter-specific aggressive interactions were noted. What is unclear is the similar temporal pattern of visitation in the case of the bulbul spp.–Golden Oriole pair at *F. microcarpa*, their preferred tree and the barbet pair at *F. drupacea*, not their preferred tree.

FRUITING fig trees, especially those that are bird-dispersed, attract avian frugivores in large numbers[1]. This has led to a number of studies on frugivore composition and their interactions at this superabundant fruit resource[2–6]. Visitations to the fruiting trees may depend on physiological needs of the frugivores and the local factors peculiar to each fruiting tree. Time spent by a frugivore at a fruiting tree would depend on its nutritional needs, diet and activity budgets. The presence of predators and the interactions among the frugivores could also affect visitation rates[7,8]. Kantak[7] surmised that the different visitation patterns of the common frugivores could be due to interference competition. This paper presents the results from a study of temporal partitioning of the fruit resource among avian frugivores visiting fruiting strangler figs in a tropical evergreen forest in the southern Western Ghats, India. The null hypothesis of no differences in the temporal patterns of visitation was tested against the alternative hypothesis of temporal partitioning of the fruit resource by the common frugivores.

The study was conducted from 21 January to 31 March 1993, at Karian Shola National Park in the Indira Gandhi Wildlife Sanctuary, Pollachi district, Tamil Nadu, India. The Karian Shola National Park (10°27'N, 76°51'E; altitude c. 765 m) is spread over 506 ha of tropical evergreen forest. It is contiguous with similar forest across the Kerala–Tamil Nadu border in the Parambikulam Wildlife Sanctuary. It is classified as the west coast tropical evergreen forest with the characteristic tree species being *Hopea parviflora* and *Messua ferrea*[9]. The national park is surrounded by moist deciduous forests and teak plantations. Most of the precipitation in this region occurs during the south-west monsoon (from June to August) but the effect of the north-east monsoon (during November and December) is also felt. This area received 1778.2 mm of rain in 1992 and 27.8 mm during the three-month study period.

A total of 123 hours of frugivory observations was conducted at three trees of *Ficus drupacea* (67 h), one tree of *F. microcarpa* (40 h) and two trees of *F. amplissima* (16 h). Observations were conducted between 7.00 AM and 5.00 PM. The bird species and their numbers were noted during every alternate 5-minute period.

The trees chosen for observations had to satisfy certain criteria. They had to have large synchronously ripening fruit crops; usually bird-dispersed fruiting characteristics in the old world tropics[1]. The trees had to be relatively shorter and located in more open areas. In

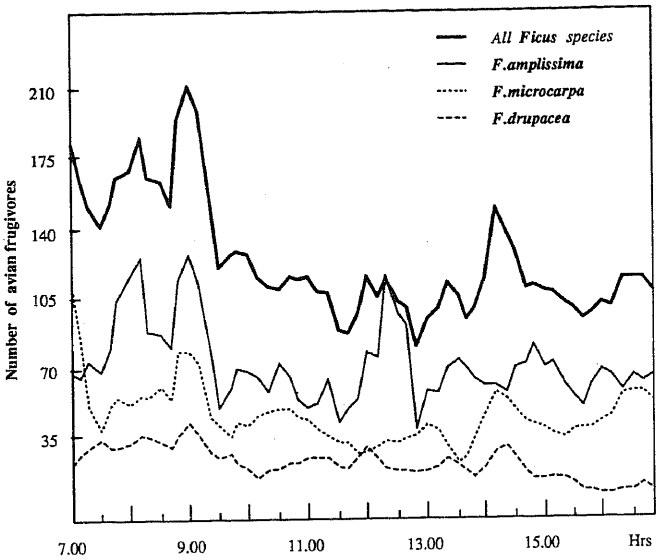

Figure 1. Temporal pattern of visitation of avian frugivores at fruiting *Ficus* trees through the day. The data presented here represent a four-day aggregate of the number of avian frugivores visiting the three *Ficus* species and a 13-day aggregate for all the *Ficus* species combined.

addition, the foliage density had to be low. This was essential to facilitate the identification of important frugivores like the Greyfronted Green Pigeons (*Treron pompadora*) and barbets (*Megalaima* spp.) which are small and green in colour and to obtain a reasonably accurate count of birds in general. This strongly constrained the number of trees that could be observed. Most of the sampled trees were present on the edges of clearings and in riparian areas within the evergreen forest.

Although these trees were chosen based on the above criteria, it is unlikely that this selection would have in any way affected the visitation of the birds both in terms of species as well as numbers to the trees. This is corroborated by the fact that despite the difference in the number of hours of observation at each species of *Ficus*, the number of frugivore species recorded was around the same (19 species were recorded at *F. amplissima*, 24 *F. drupacea* and 26 at *F. microcarpa*). Also, the seven common species that have been used for analysis of frugivore visitation pattern were recorded in fair numbers at all three *Ficus* species[10].

The visitation patterns of all the avian frugivores were studied through the day. For analysis of differences in temporal patterns of visitation, seven of the most common frugivores namely Malabar Grey Hornbill (*Tockus griseus*), Greyfronted Green Pigeon (*Treron pompadora*), Small Green Barbet (*Megalaima viridis*), Crimsonthroated Barbet (*M. rubricapilla*), the bulbuls (*Pycnonotus melanicterus gularis, P. jocosus* and *Hypsipetes indicus*), Golden Oriole (*Oriolus oriolus*) and Fairy Bluebird (*Irena puella*) were considered. The three species of Pycnonotidae were grouped together to improve the statistics as the visitation frequencies of the individual species were low. If the patterns of visitation of the three species were different, their combined data would have yielded smoother pattern. However, the combined data show a definite periodic pattern in their visitation which justifies the assumption that the visitation patterns of the three species are similar.

The number of days during which observations were conducted was not the same for all the time intervals between 7.00 AM and 5.00 PM. The bird numbers in each interval have been scaled to the median value of 13 days to analyse the temporal patterns across a day. The analysis was repeated for each of the three strangler fig species. The bird numbers were smoothened by taking an average over three successive time intervals.

A multinomial χ^2 goodness of fit test was employed to check the null hypothesis of no differences in the patterns of visitation of the common frugivores, taken a pair at a time. In order to improve the reliability of the χ^2 statistic, two constraints were imposed during analysis. Only those time intervals in which the expected number of birds was greater than 2.0 were considered. This severely reduced the number of usable time intervals, especially when the data from different *Ficus* species were considered separately. This in turn resulted in inordinately high values of significance for the null hypothesis which was in fact an artifact due to bad statistics. To avoid this artifact, only the results of those bird pairs which had at least 30 usable time intervals in common (out of a maximum of 60 through the day) have been considered[11].

The fruiting strangler figs had a continuous stream of frugivores right through the day with a major peak in frugivore activity between 7.00 AM and 9.30 AM and a much smaller one at around 2.30 PM (Figure 1). The pronounced early morning peak in frugivore activity may have been due to the increased food requirements of the frugivores at the start of a day. It seems likely then, that there will be another peak in frugivore activity at the fruiting strangler figs at the end of the day, before the frugivores turn in for the night.

The avian frugivores preferred different species of *Ficus*, occurring in large numbers at these species (Table 1). The Malabar Grey Hornbill preferred *F. drupacea*, the Green Pigeons and the barbets preferred *F. amplissima* while the bulbuls, Golden Orioles and Fairy Bluebirds showed a preference for *F. microcarpa*. It is well known that bird-dispersed figs when ripe are harvested by various size of birds, since even those with smaller gape sizes can eat the soft fruit by pecking out small pieces[12]. However, in terms of optimal utilization of the food resource, it is likely that a frugivore will try to eat the largest possible fig convenient given its gape size rather than ingest smaller figs or take bites of larger figs. We see such a trend here with the Malabar Grey Hornbill, the largest of the frugivores preferring the large fruits of *F. drupacea* (1.5–2.0 cm across[13]) while

the bulbuls preferred *F. microcarpa* which has the smallest fruits among the three *Ficus* species.

Excepting two pairs, all the 21 possible pairings of the seven most common frugivores exhibited differing temporal patterns of visitation at the fruiting strangler figs (Table 2). Kantak[7] recorded a similar result at five species of fruiting trees, including a *Ficus* species. The only two pairs which did show similar temporal patterns in visitation were the Small Green Barbet–Crimsonthroated Barbet pair at *F. drupacea* and the bulbul spp.–Golden Oriole pair at *F. microcarpa*. The reasons for the similarity in temporal visitations shown by these pairs of frugivores are not clear. What is puzzling is that while the barbet pair exhibited similar temporal pattern of visitation at a tree which was not their preferred species, the bulbul spp.–Golden Oriole pair exhibited similar visitation pattern at their preferred tree.

One could argue that at their preferred tree, the higher pressures the barbets face from the members of other congeneric species has led to the temporal partitioning of the resource. Therefore at *F. drupacea*, which is not their preferred tree and where competition from the other barbet species is likely to be lower, the closely related barbets have similar patterns of visitation. However, the bulbul spp.–Golden Orioles pair neither have similar habits nor are they closely related[14] to explain the similarity in their visitation pattern to their preferred tree.

The reasons given for temporal variations are many[7,8,15]. Predation pressures and aggression were certainly not the major reasons at Karian Shola National Park as very few instances of predatory attempts (seven in 123 hours of which none were successful) and interspecific aggression (seven in 56 hours of observation) were seen among the birds[10]. While figs are a superabundant resource, they are almost completely utilized by the frugivores[10] and one would expect competition over the resource. Perhaps past competition has moulded present frugivore behaviour and resource partitioning, and manifested in differing patterns of temporal visitations among frugivores.

In conclusion, the fruiting *Ficus* trees were host to frugivores throughout the day, with a higher activity in the early morning and mid afternoon. The major peak in the early morning could be explained by the increased food requirements of the frugivores who have started their day after a long gap in feeding. I would expect another peak in activity prior to sundown when the birds have to stock up for the night. The common frugivores occurred in larger numbers at certain species of *Ficus* and this preference is likely to be based on the optimal exploitation of a fig given the gape size of the frugivore. Most of the avian frugivores, including the two most common at each fruiting tree had differing temporal patterns of visitation to these super-abundant resources. Predation was rare and aggressive interactions between species very few which makes active interspecific competition an unlikely explanation for the differing patterns. What is difficult to explain is the similar temporal pattern of visitation of the bulbul spp.–Golden Oriole pair, at their preferred fruiting tree. Perhaps the biology and activity patterns of different species condition them to particular temporal patterns of behaviour.

Vegetational and climatic changes during recent past around Tipra Bank Glacier, Garhwal Himalaya

A. Bhattacharyya and M. S. Chauhan

Birbal Sahni Institute of Palaeobotany, Lucknow 226 007, India

Palynological studies from Tipra Bank Glacier, UP Himalaya indicate that the climate was warm moist, similar to today's, prior to 720 yr B.P. This then reverted to comparatively cold dry climate around 620 yr B.P. when the glacier might have descended down. The climate changed to warm moist regime again around 460 yr B.P.

PALYNOLOGICAL studies from glacial sediments above tree limit or alpine region of the Himalaya are limited in number[1–3]. Most of the studies on this aspect are confined to temperate and subtropical sites[4,5].

We have attempted here to understand the changes of vegetation around Tipra Bank Glacier and their relationship to glacial fluctuations using pollen data of both surface and subsurface sediments of near present day snout.

Tipra Bank Glacier (Figure 1), one of the major glaciers in Bhyundar Ganga valley of Alaknanda catchment, joins another major glacier, Rataban and together they form a common snout. Bhyundar Ganga river originates from this snout and flows through the famous Valley of Flowers and ultimately joins Alaknanda river at Govindghat near Pandukeshwar. There are fourteen other glaciers which are of small niche types. The detailed climatic data around the site is not available. A general observation in this regard indicates that the

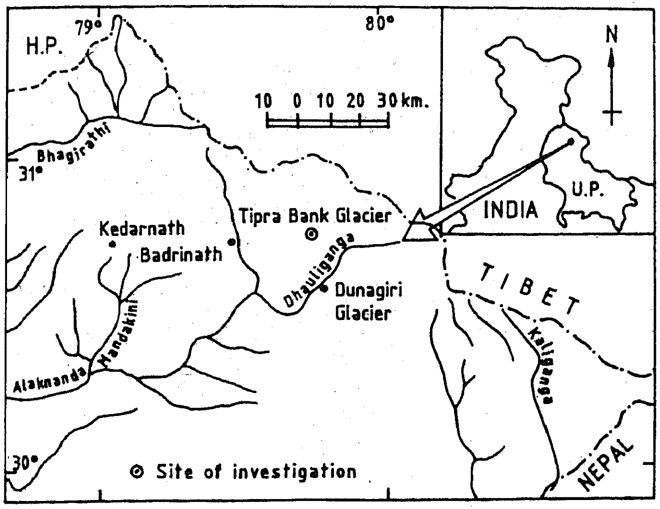

Figure 1. Sketch map showing the site of study.

precipitation is in the form of snow during the major part of the year except for frequent rains during May to September.

The area covers a large number of alpine taxa and these are mostly represented by *Aconitum* sp., *Anaphalis triplinervis*, *Androsace lanuginosa*, *Anemone* sp., *Angelica glauca*, *Artemisia* sp., *Bupleurum himalayense*, *Delphinium brunonianum*, *Geranium wallichianum*, *Geum alatum*, *Gypsophilla cerastoides*, *Heracleum brunonis*, *Meconopsis aculeata*, *Potentilla* sp., *Primula* sp., *Rubus natans*, *Saussurea gossypiphora*, *Saxifraga diversifolia*, other members of Caryophyllaceae, Chenopodiaceae, etc.

The trees in the subalpine zone today extend up to about 2 km south-west of glacier terminus, while scattered scrubs or small trees of *Betula utilis*, *Rhododendron campanulatum*, *Salix flabellaris*, *S. lindienana*, etc. are found even upstream of the glacier snout. Along the timber line, *Abies pindrow* and *Betula utilis* are the dominant species. Besides, the randomly distributed alpine bushes comprise *Acer cappadocium*, *Cotoneaster acuminata*, *Juniperus communis*, *J. squamata*, *Rhododendron lepidotum*, etc.

The samples were collected from the valley floor which consists mainly of glaciogenic deposits overlain at places by talus material. The present-day glacier terminus lies about 3 km NE of the Valley of Flowers. The present-day geomorphological features indicate that this area was occupied by the then Tipra Bank Glacier as evidenced by the existence of lateral, terminal and ground moraines. Towards downstream in Valley of Flowers, these evidences are not visible. Instead, the features indicate a fluvial environment. Quite a few talus cones and fans exist between the Valley of Flowers and the glacier terminus.

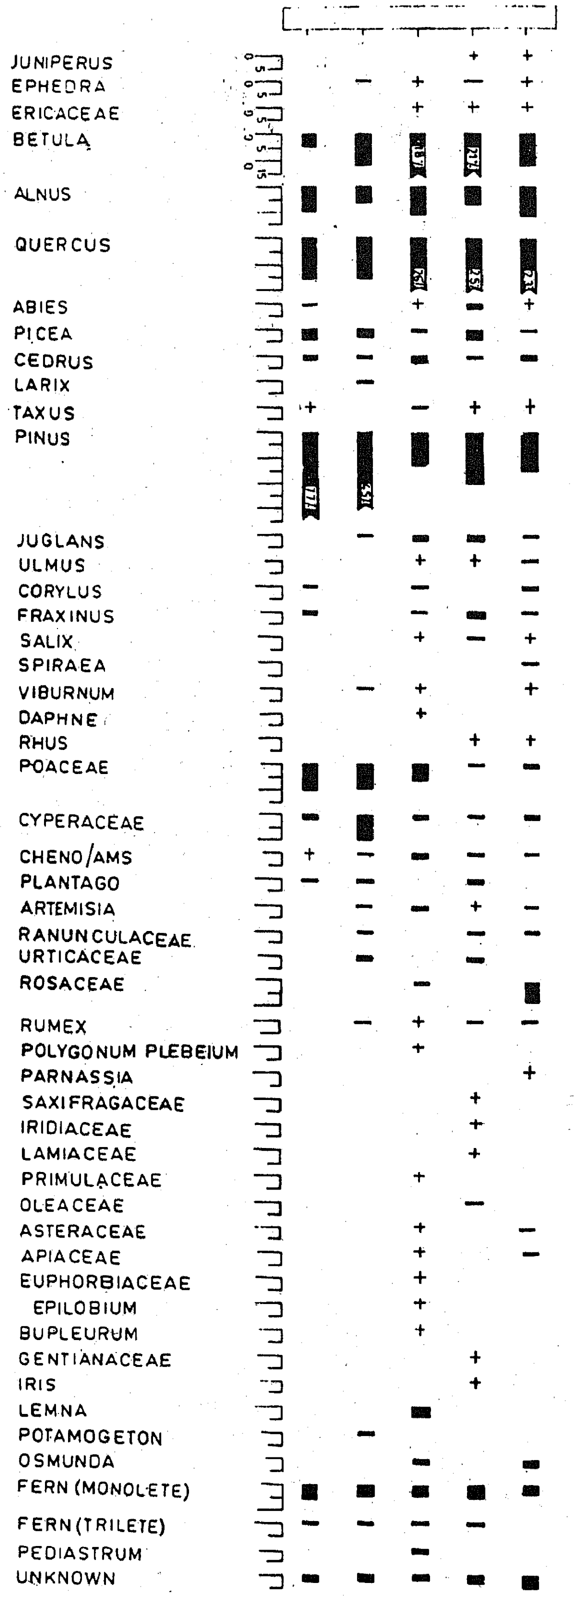

Figure 2. Recent pollen spectra from Tipra Bank Glacier, Garhwal Himalaya.

Table 1. ^{14}C dates and calendar years

Depth	Nature of samples	Dates	(yr B.P.) (^{14}C)	Calendar years (yr AD)
50–60 cm	Black soil	BS-437	460 ± 100	1401–1487 (ca.)
60–70 cm	Black Soil	BS-438	620 ± 90	1275–1408 (ca.)
70–80 cm	Black soil	BS-436	720 ± 90	1235–1300 (ca.)

Materials for the present study have been taken both from surface and a small profile. For surface samples, moss cushions from five places were collected in a transect at different intervals to understand modern pollen vegetation relationship of this site. For the subsurface samples, an 80 cm deep trench was dug along the bank of Tipra stream and 5 samples consisting of black soil at an interval of 5 cm (except a 10 cm interval between 60 and 70 cm depth) were collected for pollen analytical investigation.

Besides, materials were also collected at three different intervals from this trench for radiocarbon dating. These materials have been dated at the Radiometric Laboratory of BSIP. The ^{14}C dates and calendar years are given in Table 1.

The ^{14}C dates are converted to calendar years so that the events of the present study could be related to other evidences under the same time scale. In calibration, 'O' yr BP of ^{14}C date is taken equal to AD 1950. Since the change of atomospheric radioactivity, ^{14}C data need to be recalibrated against tree ring dating. Details of the calibration of ^{14}C date to calendar years have been given elsewhere[6]. Both surface and subsurface samples were analysed using usual pollen analysis technique[7].

Five surface samples (moss cushions) analysed from the vicinity of the snout provide database regarding representation of modern pollen in relation to the extant vegetation (Figure 2). This study shows *Pinus* 15–77% followed by *Quercus* 15–26%, *Alnus* and *Betula* 2–5% each, *Picea* 1–5%, *Juglans* and *Cedrus* 1–4% each and 1% each of *Abies* and *Fraxinus*. The shrubby elements, viz. *Juniperus*, *Rhus*, *Daphne*, and *Spiraea* are extremely low and sporadic. Among the non-arboreals, Poaceae (1–12%), Cyperaceae, Cheno/Ams, *Artemisia*, Ranunculaceae (under 2% each) and *Plantago* and Rosaceae (1–8% each) are comparatively better represented than *Polygonum plebeium*, *Parnasia*, *Iris*, *Epilobium*, Saxifragaceae, Iridaceae, Primulaceae, Oleaceae, Asteraceae, etc. which are represented by under 1% each. Fern spores (monolete 4–6%, trilete 2–3% and *Osmunda* 2%) are also recorded frequently in the samples.

A pollen diagram (Figure 3) has been made only from five pollen spectra which are dealt with below along with their equivalent ^{14}C dates.

Around 720 ± 90 yr B.P. the pollen spectra are characterized by high frequencies of *Pinus* (10–24%)

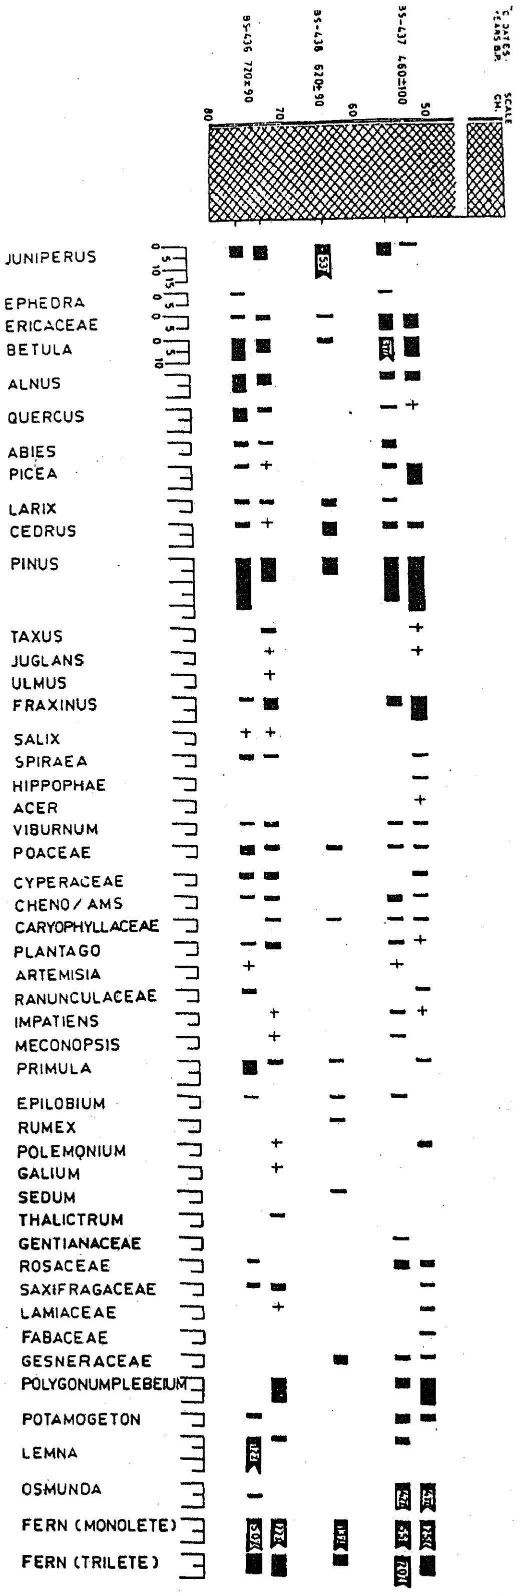

Figure 3. Pollen diagram from Tipra Bank Glacier, Garhwal Himalaya.

followed by *Betula* (5–10%), *Alnus* (4–10%), *Quercus* (2–6%), *Juniperus* (5–7%) and *Fraxinus* (1–5%). The other tree taxa such as *Abies, Cedrus, Larix, Taxus* and Ericaceae (under 2% each) are consistently represented in low frequencies. *Juglans, Ulmus* and *Salix* (under 1% each) are met with scantily. The shrubby vegetation is poorly represented (under 2% each) by *Spiraea* and *Viburnum.*

The non-arboreals are mainly represented by *Primula* (2–7%), Poaceae (2–5%), Cyperaceae, Cheno/Ams, *Plantago* and *Saxifraga* (2–3% each). *Artemisia, Impatiens, Meconopsis, Epilobium, Rumex, Polemonium, Galium, Sedum, Thalictrum,* Rosaceae and Lamiaceae (under 1% each) are extremely low and sporadic. Aquatic vegetation is represented by *Lemna* (2–12%) and *Potamogeton.*

Fern spores (monolete 22–50% and trilete 9–10%) are recorded in preponderance.

During 620 ± 90 yr B.P. in general, a comparatively poor assemblage as well as low frequencies of most of these taxa have been noticed, except *Juniperus* which shows a drastic enhancement (53%). *Cedrus* (6%) and *Larix* (3%) are also slightly better represented, whereas *Pinus* (11%) declines considerably. The ground vegetation is scantily represented by Poaceae (2%) and under 1% each of Caryophyllaceae, *Primula, Epilobium, Rumex* and *Sedum.* Fern spores (monolete 13% and trilete 5%) decline sharply.

During 460 ± 100 yr B.P. *Betula* (10–31%), *Pinus* (20–25%), *Picea* (2–9%) and *Abies* (3%) indicate the increased frequencies, but *Juniperus* (6–1%) declines abruptly. The other taxa such as *Fraxinus* (3–9%), *Alnus* (3–4%) and *Quercus* (1–2%) reappear after a lapse during the preceding phase, whereas *Ephedra, Taxus, Juglans, Spiraea, Viburnum, Acer* are sporadic and low (under 1% each).

The non-arboreal taxa are chiefly represented by *Polygonum* (3–10%), Rosaceae (2–4%), Cyperaceae and Cheno/Ams (1–3% each) and Caryophyllaceae (2%), whereas Poaceae, *Polemonium* and *Plantago* (under 2% each) are recorded in low values. Aquatic elements, viz. *Potamogeton* (3–4%) and *Lemna* (3%) are better represented than before. Fern spores (monolete 25–55%, trilete 10–20% and *Osmunda* 41–42%) have been recorded abundantly.

In spite of limited sample size, the study provides a synoptic view of the vegetation changes in relation to glacial fluctuations from a glaciated site where very little work has been done because of nonavailability of suitable sediments for both ^{14}C dating and pollen analysis. In this site an alpine-scrub vegetation had occurred prior to 720 ± 90 yr B.P., i.e. around 1200 A.D. in which thermophilous broad-leaved taxa, *Betula, Rhododendron* (Ericaceae) along with herbs like grasses, sedges, Cheno/Ams, *Primula* were the major elements. The thickets of *Juniperus* and *Ephedra* were most probably confined to the rocky habitats. The vegetational composition signifies that the region was under the impact of warm and moist climate during this period. This is also well corroborated by the abundance of fern spores during this phase. The fair amount of pollen of temperate broad-leaved taxa such as *Alnus, Quercus* together with conifers, *Pinus, Abies* and *Picea* during this period could be indicative of the extension of the temperate belt in response to favourable climatic conditions.

Around 620 ± 90 yr B.P., i.e. 1275–1408 A.D., the broad-leaved alpine-scrub vegetation was succeeded by the Juniper-scrubs as evidenced by high values of *Juniperus* and corresponding decline of broad-leaved elements from this site. The non-arboreals comprising grasses, sedges, Cheno/Ams together with ferns also grew meagrely. In general, the poor vegetation cover during this period implies deterioration of climate which was probably colder and drier than today's. Besides, the poor representation of conifers and other tree taxa also suggests that the tree line might have distantly located under the effect of this cold climate.

Thereafter, around 460 ± 100 yr B.P., i.e. around 1401–1487 A.D. and onwards, the summer temperature might have increased again to an extent to support small trees or scrub of *Betula, Alnus, Quercus* and *Rhododendron.* A good amount of pollen of other trees such as *Pinus, Picea, Abies, Cedrus* also indicates that some of these taxa especially *Abies* and *Picea* which grow near tree line had occurred around this site. Decline of *Juniperus* and increase of ferns also indicate less aridity during this period.

The present study based on an analysis of a small number of samples collected from near the snout of Tipra Bank Glacier has provided a broad understanding of vegetational changes *vis-à-vis* glacial fluctuation since around 1200 A.D. In general, two climatic phases, viz. warm moist to cold dry to warm moist again could be recognized in the region. In the beginning, around 1200 A.D. the climate was warm moist and the glacier reached almost to its present position. Around 1275–1408 A.D., however, the climate deteriorated and the glacier might have advanced towards lower elevation. Subsequently, with the amelioration of climate during 1401–1487 A.D. the glacier had started retreating. Presence of several recessive moraines also indicates that the glacier had retreated earlier. In comparison to the global scenario, the climatic amelioration recorded around 1200 A.D. falls within the duration of medieval warm period which is believed to have occurred around 1200 A.D. to 1400 A.D. in the northern hemisphere. Subsequent deteriorations around 1275–1408 A.D. lie within bracket years of climatic changes during Little Ice period. Corresponding to this climatic trend, a climatic amelioration was recorded during 1150 A.D. to 1450 A.D. which reverted to cold and dry again after 1450 A.D.; at Batal, Rohtang Pass, Himachal Pradesh[2].

Current Science

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final version in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred.) A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts, subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.).

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

The Collected Papers of Albert Einstein – The Berlin Years: Writings 1914–1917. Volume 6. A. J. Kox, Martin J. Klein and Robert Schulmann, eds. Princeton University Press, 41, William Street, Princeton, NJ 08540, USA. 1996. 626 pp. Price: Clothbound $85.

The programme of publishing the collected papers of Albert Einstein has been on since the mid-eighties or so, as a joint effort of Princeton University Press and the Hebrew University, Jerusalem, where most of the Einstein archives are held. This is a massive project expected to finally comprise a total of some forty volumes. Some are devoted to Einstein's voluminous correspondence in various phases of his life, others to his scientific papers divided into significant periods. Along with the so-called documentary edition containing the documents in their original languages, mainly German, a series of invaluable English translations is also being produced by Princeton University Press. Volumes 1, 2 and 3 of the latter have been reviewed in *Current Science*, 1996, **71**, 78 and Volume 5 in *Current Science*, 1995, **69**, 882.

The present volume published in 1996 is the sixth in the Documentary Edition series, and covers the period 1914–1917. This was the start of Einstein's Berlin Years. In early 1912, he had become Professor at the ETH in Zurich, but in April 1914 Einstein moved to Berlin to accept a specially created research professorship, with no teaching duties, at the University of Berlin, under the aegis of the Prussian Academy of Sciences. From the physics point of view this period is most important because the general theory of relativity (GTR) reached its final formulation, and the two fundamental papers on the processes of absorption and emission of photons by matter appeared. This volume has all the original papers in German (except for one in English), and the editors Kox, Klein and Schulmann have added extremely illuminating footnotes, commentary and historical material often bringing matters up to date to present times. It is amusing to notice that many of these papers were published in about a week after submission to the journal concerned – far away indeed from the situation today!

The major part of the contents of the volume deal with the progress of Einstein's ideas on GTR. Three early papers with Marcel Grossmann are concerned with formulations in which the subtle interplay between the mathematics and the physics of general covariance was still far from clear. Indeed in these early papers and up to a few days before the final formulation on 25 November 1915, Einstein had convinced himself that the sought-for field equations for gravitation should allow unambiguous determination of the metric tensor components for given energy momentum tensor as source, and for given boundary conditions. For this reason, the permitted degree of covariance under general coordinate transformations was at various stages limited in different ways – at one point, linear transformations alone; then transformations with unimodular Jacobians alone; and finally imposition of the requirement that the determinant of the metric tensor itself be unity! Later Einstein realized that in some of these restricted versions even rotational covariance would be lost. For these reasons, almost all the earlier papers on GTR (including a review) in this volume are of purely historical value. As one sees the ideas slowly gather strength till they finally break through into transparent clarity, one appreciates the depth of meaning in Einstein's later statement: 'But the years of anxious searching in the dark, with their intense longing, their alternations of confidence and exhaustion and the final emergence into light – only those who have experienced it can understand that.'

At an earlier stage it is amusing to see that after Einstein's inaugural lecture to the Prussian Academy in July 1914, in the discussion, Max Planck wondered why it was necessary to generalize special relativity to include the possibility of accelerated or noninertial observers! Only now may we smile at such incidents.

The first and classic systematic exposition of GTR, Document no. 30, appeared in May 1916; later it appeared as a book as well. The 'summation convention' was used here for the first time.

The full German text of Einstein's first popular exposition of both special and general relativity, completed in 1916 and published in 1917, is given in this volume. This book went through many editions and translations and at various stages Einstein added appendices and extra material in abundance.

The first application of GTR to cosmology, and the introduction of the cosmological constant, date to February 1917, and are reproduced as Document no.43. There are also some short notes on Hamilton's variational principle for GTR. It was only as late as 1931 that Einstein admitted to a change of heart and withdrew the cosmological constant as unnecessary and unjustified.

Around the same period that he was struggling with the formulation of GTR, Einstein also undertook some experiments with Wander Johannes de Haas (son-in-law of Lorentz) to prove the existence of Ampere's circulating molecular currents. More than a century earlier, Ampere had suggested that microscopic current loops were the ultimate sources of magnetism, and Einstein and de Haas set out to prove this by ingenious experiments. While they were in a sense successful, it must be remembered that this was well before the discovery of the spin of the electron and its associated magnetic moment; so later the limitations of the Einstein–de Haas work in the quantitative sense slowly became clear. All the original papers by Einstein and de Haas, and some by the former alone, are included in this volume.

Turning to quantum theory, there are three significant papers. The first two relate to Einstein's persistent attempts to derive Planck's Law in various ways; they introduce his famous A and B coefficients, the concept of stimulated emission (basic to functioning of lasers today) and also the concept of photon momentum. Einstein was very pleased with these efforts since he wrote to Michele Besso: 'A splendid idea on the absorption and emission of radiation has dawned on me'. The third one on quantum theory attempts an invariant formulation of the Bohr–Sommerfeld–Epstein quantization conditions of the old quantum theory – here Einstein was trying to free himself from the limitation to separable and integrable systems, and to express the quantization in a global and invariant manner. It is interesting and amazing that these ideas of his in 1917 find echoes in the dynamics of chaotic systems today.

Other highlights of this volume are

Einstein's first ever political statement – 'Manifesto to the Europeans' dated mid-October 1914 – lecture notes for courses given in winter 1914–1915 on relativity, and notes by a student on the Wolfskehl Lectures given at Gottingen in 1915.

The quality of production of this volume, as one might expect, is excellent. One awaits with anticipation and eagerness the appearance of its companion English translation.

Physics for Engineers. M. R. Srinivasan, New Age International Publishers, 4835/24, Ansari Road, Daryaganj, New Delhi 110 002. 1996. 519 pp. Price not known.

How much physics should be included in the curriculum of a 4-year undergraduate course in engineering? What kind of physics should be taught, and how should it be sequenced?

These questions are important – not only in their own right, but also because they are relevant to a relatively large segment of our student population. After all, a degree in engineering or medicine is widely regarded in our society as one of the pre-requisites for eternal bliss (the others being a fair bride with a handsome dowry, male offspring, non-stop film music on loudspeakers, and a national cricket team that always wins). They are also questions that have no easy answers. One gathers from the book under review, however, that for students of engineering in Karnataka the study of physics is restricted to a single semester in the first year. The stated aim of the book is to provide a comprehensive text geared to meet this requirement, taking 'the syllabus as a guide for the organization' of the book.

It is at once evident that this places severe constraints on the author. On the one hand, there is his laudable and unexceptionable value system – he urges students to study physics in more detail and depth, with the assurance that 'a proper study of physics would certainly enhance your capabilities as an engineer'. On the other hand, there is the syllabus 'to be covered' – preparing the students to perform the rituals attendant upon the examination system – namely, the appeasement of minor deities named derivations, numericals, short notes, objectives, and so on! The gap between these two poles has become virtually unbridgeable. The author has opted to cater to the second system. Within the parameters chosen, the outcome is a reasonably good book. To understand its limitations, however, it is necessary to understand the two major problems posed by the system, and how they affect even the best of efforts in our textbook scene.

The first difficulty is the inability or unwillingness (or both) of most of our students (and, one might add, many of our teachers) to work out intermediate steps on their own. This has led to the stabilization of a ruthlessly efficient engine: a (vicious) cycle of spoon-feeding and regurgitation in which the working substance is a litany of trivial algebra and arithmetic. Textbooks that do not work out all the steps explicitly are shunned – they are either 'foreign books' or 'foreign-type books' that are 'not suitable for our conditions'. The 'successful' textbooks are poorly printed, excessively bulky hack works that waste a lot of paper and convey little of real substance, let alone challenge the ingenuity or inspire the imagination of the student. Worked out problems most often comprise little more than routine substitution of numerical values in formulas and subsequent simplification in excruciating detail – the argument being that our students only understand material presented in this manner. This is identical to the way our film-makers justify the nauseating trash they purvey as 'what the audience out there wants'. The creation of a vicious cycle in each case is then a mathematical certainty.

The second difficulty is in striking a balance between 'theory' and 'application', especially within the strong constraints posed by a curriculum in which the time allotted to physics is quite meagre. As technology progresses, it becomes necessary to incorporate at least some of the advances into the already abbreviated (4-year instead of the earlier 5-year) BE or B Tech programme (examples: computer-aided design, robotics, . . .). How is this done? Almost always, by removing or reducing portions perceived as unessential, or at least less essential. This is how the 'pure' science part of the engineering curriculum has shrunk over the past 15 years or so – in physics, from a rough average of at least 8 semester-long courses to no more than 3, more often 2, or even 1 (as seems to be the case in Karnataka, and elsewhere too). What happens next in such a situation in tragic: inexorably, what is 'old' gets identified with what is obsolete, and what is new gets confounded with what is relevant. The baby gets thrown out with the bath water: the study of basic principles is eliminated in favour of an inevitably superficial coverage of a patchwork quilt of topics regarded as modern and hence 'relevant' and 'application-oriented', in the fond hope that students who merely hear the magic words or acronyms will automatically become the suppliers of the 'deliverables' of 'futuristic technology'!

It is perhaps considerations along these lines that have dictated the structure of the syllabi of various universities, which the book under review presumably reflects. The sequence of chapters reads: acoustics, nondestructive testing , geometrical optics, interference, diffraction and polarization, fibre optics, laser (*sic*), vacuum science and technology,. . . . This is followed by electronic structure of atoms, semiconductors, dielectric materials, magnetic materials, superconductivity, and *then* magnetism and electricity! Heat and thermodynamics comes next, and then comes the final chapter, basic electronic components – essentially a description of different kinds of resistors, capacitors and inductors. With such a quixotic sequencing of topics, the treatment can only be a largely descriptive listing of facts. Can the average student taking such a course be blamed, then, if he goes away with the impression that physics (which he 'cleared' in his first year by writing short notes on any three out of the following five: noise and its insulation, electron microscope, holography, diffusion pump, energy band theory of crystals (*sic*)) is just a grab bag of disconnected topics like the ones listed above, with little or no unified perspective or guiding principle, half of which can be ignored as it 'was asked last year' and the rest of which is best forgotten in favour of 'real engineering'?!

It is the *system* to which the book under review caters that is under criticism, rather than the book *per se*. Within its limitations, it is an honest effort, certainly better than most other books of its type. The figures are reasonably clear, as is the language. There are not too many places in which trivial algebraic simplification is written out in detail. The author has taken care to avoid errors and misinformation to the extent possible – although there are passages that either beg the question (example: Sec. 16.5 on the zeroth law of thermodynamics) or are too obtuse to be of any help in understanding the matter under discussion (examples: Sec. 8.6 on holography, Sec. 11.18.1 on light emitting diodes). On the whole, one may regard the book as a mild form of medicine that may alleviate some of the symptoms of the malady pervading the system, without attempting to cure the illness itself.

But is there no satisfactory solution to the dilemma itself – namely, the problem of striking a balance between basic principles and applications in a highly time-constrained curriculum? This reviewer believes that there does exist a reasonable solution (modulo adjustments of detail depending upon the actual circumstances). When one has to make an absolute choice between a basic principle that has very wide applicability, and a specific application whose technical details are in any case too complex to be dealt with satisfactorily in an elementary course, the correct choice is virtuous and clear! A careful exposition of the former, with the help of simple illustrations, would stand the student in good stead in his subsequent career, both educational and professional. To paraphrase a thoughtful colleague's remark, the student would then have been empowered rather than bedazzled, and that's a good thing to be.

Ecology and Sociobiology of Indian Primates. M. D. Parthasarathy, Dynaram Publications, 20, 1st Floor, South Cross Road, Basavanagudi, Bangalore 560 004. 119pp. Price: Rs 100, $10.

It is a small monograph on the ecology and sociobiology of some Indian (rather south Indian) primates, written lucidly after proper scientific understanding of primates. The monograph, appropriately illustrated with self-explanatory line drawings, provides a unique overview on many hitherto unknown social behaviour in primates. It has covered the different categories of behaviour and provides a detailed account on loris, the bonnet macaques, lion-tailed monkey, Hanuman langur and Nilgiri langurs. The book provides a synthesis of the most current information and theoretical significance. The language used is not very difficult or complicated even for a learner primate researcher. It is a monumental piece of work which will be of immense interest and use to diverse readers specially for researchers, the academic community and scholars alike for comprehending primate eco-ethology. In my opinion, it is a commendable job by M. D. Parthasarathy which will guide young ethologists.

L. S. RAJAPUROHIT

Department of Zoology,
JN Vyas University,
Jodhpur 342 005, India

Atlas of Paleogene Ostracodes of Rajasthan Basin. ***Paleontol. Indica*, No. 4.** Anil Bhandari. KDM Institute of Petroleum Exploration, Dehradun 248 195. 157 pp. Price not known.

For the first time there has been a sincere effort to prepare an atlas of Paleogene ostracodes of Rajasthan basin. An exhaustive study of the surface outcrop samples and subsurface well samples (from 5 wells) were examined by the author. One hundred and twenty four species of which eleven taxa are in open nomenclature are included in the work, illustrated excellently in the plates.

Ostracodes are mainly utilized for environmental interpretations and their scope for dating of rocks is limited due to their benthic habitat and strong response to environmental changes. The author could have included a chapter on environment in this publication.

The author has contributed an excellent work more of which must be coming in the near future. The data available from different sedimentary basins are enormous and dedicated workers in ONGC must contribute to this field. Workers in India and abroad are awaiting anxiously for more atlases and if possible, a stereo-atlas similar to that published by Leicester University, UK. The stereo-atlas will clear the confusions in taxonomy, since examining the stereo-pairs under ordinary stereoscope is easier than going through actual specimens or holotypes, etc., Bhandari's work is highly appreciated and will benefit a lot of research workers in this field.

Pancheti Koteswaram – An obituary

P. K. Das

With the passing away of Pancheti Koteswaram (1915–1997) on 11 January this year, our country has lost an eminent meteorologist of the postwar period. His best contributions were in synoptic meteorology and practical weather forecasting for which he will be remembered by his colleagues. His ability in these fields was coupled with an innovative approach to emerging areas of new technology. He had a visionary outlook for the growth of Indian meteorology.

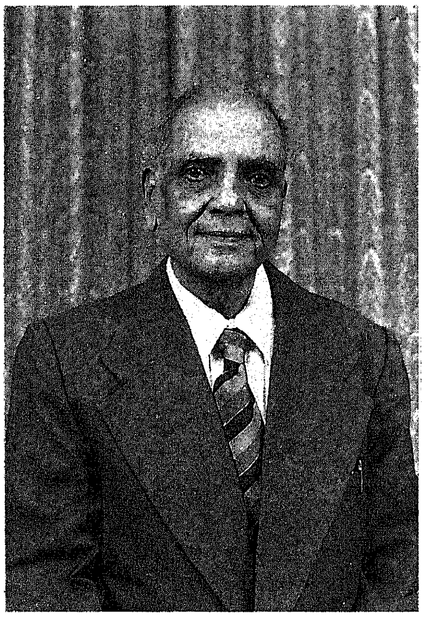
Koteswaram was born on 20 March 1915 at Nellore, a small town in coastal Andhra Pradesh. In later life he would often tell us about a cyclone which struck Nellore in 1927, when he was a boy of twelve. This, he said, generated a lifelong interest on tropical cyclones.

His early education was received at Nellore. In 1931, he was placed first in the Intermediate examination of Andhra Pradesh. The Sir R. Venkataraman gold medal was awarded to him by Andhra University for this achievement. Later he joined the Presidency College at Madras from where he graduated in 1934 with an Honours degree in Physics. Thereafter, he worked in junior academic positions at different colleges of Andhra Pradesh. Around 1936 he embarked on a research project on the Raman effect, under the guidance of T. Ramakrishna Rao. He received his doctorate degree (D Sc) in 1939 from Madras University. His thesis was on 'Studies of associated liquids by the Raman effect'.

Koteswaram joined the India Meteorological Department (IMD) in August of 1940. The early part of his career was spent on operational weather forecasting at different meteorological centres of India. Interestingly, one of his early postings was at the Cyclone Warning Centre at Alipore, in Calcutta. Here he acquired the basics of cyclone prediction and warning.

I was introduced to Koteswaram in 1949, when I joined the Meteorological Department at Poona (now Pune). I was impressed by his command over data and data-related problems. Around this time Koteswaram become interested in the upper air over India. This led to his discovery of an easterly jet stream over peninsular India. Its appearance provided Indian forecasters with a valuable tool for detecting the arrival of the summer monsoon.

As mentioned earlier, Koteswaram's other area of interest was on tropical cyclones. Once a cyclone was detected, he would follow its path and predict its future with meticulous care. I remember spending many hours with him debating the observations on a weather chart. He loved a debate, but like Voltaire, the French philosopher, he would often end by saying: 'I differ from you emphatically, but I will defend your right to differ till the last drop of my blood'. Differences of opinion seldom led to any permanent rancour.



As a sequel to his work on tropical cyclones and the easterly jet stream, there were invitations for him from many centres abroad. He went to the University of Hawaii in 1961 as a research scholar. Similar assignments were provided for him by the University of Chicago and the National Centre for Atmospheric Research (NCAR) in the USA.

Koteswaram was elevated to the top position of the Meteorological Department, the Director General of Observatories (DGO), in 1969. He was due to retire in 1973, but his work earned him a two-year extension up to March 1975. The Government of India awarded a 'Padma Bhushan' to him in 1975. After retirement, he worked as a consultant with the government of Iran up to 1977. Subsequently, he settled down at Waltair as an Emeritus Professor of Andhra University, and whenever a cyclone was brewing near Andhra Pradesh he was always present at the nearby meteorological office to watch its movement. He named his house in Waltair 'Varsha' (rain), which was not surprising when we consider his love for the atmosphere. 'Varsha' was a pleasant meeting place for his students and colleagues because of the warm hospitality of Koteswaram and his family.

During his tenure as the Director General of Observatories, Koteswaram introduced several new ideas and innovations. One of his early contributions was to improve the quality of upper air data. His initiative led to a uniform design for the radiosondes used in India. Automatic Picture Transmission (APT) facilities from the US Weather Satellites were introduced by him. Meteorological radars in the X-band (3 cm) and the S-band (10 cm) were also introduced. As these radars were manufactured by Bharat Electronics Ltd., Koteswaram tried to make the country as self-reliant as possible in the then emerging area of radar meteorology.

True to his abiding interest in tropical cyclones, Koteswaram took vigorous steps to introduce a close network of cyclone detection radars along the east and west coasts of India. Along with the APT facilities, these innovations did much to improve cyclone detection and prediction in India. Developments in instrumental technology were followed by cyclone warning centres in each of the coastal states of our country. An annual meeting of the Cyclone Review Committee also helped to keep meteorologists aware of the latest developments in this field.

India played a leading role in international collaboration during Koteswaram's time. He was largely instrumental in setting up a Regional Meteorological Centre (RMC) and a Regional Telecommunication Hub (RTH) at New Delhi. These centres were a part of World Weather Watch (WWW), a global project that was launched by the World Meteorological Organization (WMO) to improve the collection and analysis of data at the principal meteorological centres of the world. Koteswaram was also closely associated with the International Indian Ocean Experiment (IIOE) of 1959–1965. For his constructive role in the different WMO projects, Koteswaram was elected a member of the Executive Committee of WMO. Later, he was made the Third Vice-President of WMO. He was the first Director General from India to receive this honour.

Outside his professional activities, Koteswaram was a fun-loving personality with a keen sense of humour. He loved a light-hearted joke, even sometimes on himself. His humour often enlivened a dreary discussion. This made life much easier for others.

He died after a brief illness and is survived by his widow, four daughters and a son.

Erratum

Solar eclipse and neutrinos (*Curr. Sci.*, 1996, **70**, 848–849)

Mohan Narayan, G. Rajasekaran and Rahul Sinha

The neutrino emerging from the sun is an incoherent mixture of mass eigenstates and hence the correct quantum mechanical calculation of the enhancement during the eclipse is different from the classical treatment of eqs (2) and (3). Although the corrected numerical results are similar to those in Figure 1, the enhancement now occurs at still smaller values of δ and these will be presented in a detailed paper.

Physical Research Laboratory

Navrangpura, Ahmedabad 380 009

(Advt. No. 6/97)

OPPORTUNITIES FOR RESEARCH AND TRAINING

Physical Research Laboratory, Ahmedabad offers excellent research opportunities in various areas of Theoretical and Experimental Physics as outlined below:

ASTRONOMY AND ASTROPHYSICS: Infrared and Optical Astronomy; Solar Physics (Udaipur Solar Observatory).

EARTH SCIENCES AND SOLAR SYSTEM STUDIES: Geochemistry and Geochronology; Oceanography; Palaeoclimatology; Solar System and Meteorite Studies.

LASER PHYSICS AND QUANTUM OPTICS

PLANETARY ATMOSPHERES AND AERONOMY: Earth's Middle Atmospheric Studies; Ionospheric Physics; Laboratory Astrophysics; Planetary Atmospheres.

THEORETICAL PHYSICS: Astrophysics; Atomic and Molecular Physics; High Energy Physics; Nuclear Physics; Plasma Physics; Nonlinear Dynamics; Computational Physics.

Bright and highly motivated students and young scientists are encouraged to apply for research and training under the following categories:

a. Ph D PROGRAMME: M Sc students with First Class or High Second Class degree in Physics/Chemistry/Applied Mathematics/Geology/Geophysics/Oceanography and with Physics and Mathematics as subjects in their B Sc degree are selected in this programme to pursue research leading to Ph D degree under the guidance of Senior Scientists of the Laboratory. Those who are appearing for their M Sc degree examination this year are also eligible to apply. Research Scholars are selected on the basis of the academic record, written test and personal interview. They will be required to undergo course work in various topics during the first year and continuation of the research scholarship is subject to successful completion of this course work.

b. PROJECT ASSOCIATESHIP PROGRAMME: M Sc students with First Class or High Second Class degree in Physics/Chemistry/Applied Mathematics/Geology/Geophysics/Oceanography, and with Physics and Mathematics as subjects in their B Sc degree are selected in this programme to work in association with Senior Scientists in specific experimental programmes and to participate in the associated theoretical/modelling activities. Those who are appearing for their M Sc degree examination this year are also eligible to apply. Research aptitude is an important desirable qualification. The candidates are selected on the basis of their academic record, written test and personal interview. They will be required to develop appropriate experimental skills and theoretical modelling capabilities as required.

The Project Associateship will be awarded initially for one year, but may be continued for up to three years depending on the progress made by the individual. A few of the selected Project Associates who do exceptionally well may be considered for suitable permanent positions in the Laboratory.

c. POST DOCTORAL RESEARCH PROGRAMME: Young Scientists with Ph D degree in Physics, Chemistry or any branch of Earth Sciences and preferably having experience in these fields are selected as Post Doctoral Fellows to do research in any of the fields mentioned above. Those who have submitted their Ph D thesis are also eligible to apply. Tenure of the Post Doctoral Fellows will be for one year and is extendable for another year subject to satisfactory progress.

Scholarship/Fellowship

a. For Ph D PROGRAMME: Rs 2800/- per month plus medical care. The scholarship may be raised to Rs 3000/- per month after two years and to Rs 3200/- per month after four years subject to appropriate evaluation. A book allowance of Rs 3000/- per year for four years, starting from the first year of Research Scholarship, is also provided. Selected candidates are provided accommodation in the Students' Hostel.

b. For PROJECT ASSOCIATESHIP PROGRAMME: Rs 3500/- per month plus medical care. Hostel facilities at a nominal rent or house rent of Rs 650/- per month (in lieu of non-availability of hostel accommodation) may be provided during the Associateship period.

c. For POST DOCTORAL RESEARCH PROGRAMME: Rs 4000/- to Rs 4500/- depending on the experience plus medical care. In case of non-availability of accommodation, house rent of Rs 650/- per month will be given.

Procedure for application

For Ph D/PROJECT ASSOCIATESHIP PROGRAMMES: Additional information and application forms for the PhD Project Associateship programmes can be obtained from

The Administrative Officer-I,
Physical Research Laboratory,
P.O. Box No. 4218,
Navrangpura, Ahmedabad 380 009.

Duly completed application forms should reach the above address **on or before 10 May 1997**. Selected candidates called for the written test and interview from outstations will be paid to-and-fro second class railway/bus fare (whichever is less) by the shortest route from the address given in the application.

For POST DOCTORAL RESEARCH PROGRAMME: The application on plain paper for Post Doctoral Fellowship containing (a) bio-data and list of publications, (b) highlights of thesis (c) brief research proposal should be sent to:

The Dean
Physical Research Laboratory,
P.O. Box No. 4218,
Navrangpura, Ahmedabad 380 009.

In addition, the candidate should arrange for at least two letters of recommendation to be sent directly to the above address. The last date for receiving the completed application is 30 May 1997. Candidates called for interview from outstations will be paid to-and-fro first class train/bus fare by the shortest route from the address given in the application.

MEETINGS/SYMPOSIA/SEMINARS

IIIrd CME in Haematology & Haemato-Oncology

Date: 17–21 May 1997
Place: Mumbai

IIIrd Continuous Medical Education in Haematology is oriented towards PG students and senior staff members from pathology, paediatrics and medicine. It includes both diagnostic and therapeutic aspects.

Training Course in Geological Mapping in Volcanic Terranes (Deccan Traps)

Date: 3 weeks from 10 September 1997
Place: Nagpur

Geological Survey of India (GSI) Training Institute is organizing a training course sponsored by Department of Science & Technology (DST), under the SERC Winter School Programme. The course will consist essentially of field training with due complement of theoretical lectures. The course is opened to Research scholars/Lecturers from universites/colleges and professional geologists from Central and State Government Organizations and Institutions.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted.

Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine. G., in *Biology of Bats* (ed. Wimsatt. W. A), Academic Press, New York. 1970. vol 1, pp. 319–322.

Dorothy Hodgkin

The articles in the special section (**page 447–489**) on Dorothy Hodgkin in this issue are based on a one-day symposium held in her memory on 12 July 1996 at the Royal Society, London, organized by the British Crystallographic Association. The occasion marked the formal release of the *Collected Works of Dorothy Crowfoot Hodgkin* published in three volumes by the Indian Academy of Sciences. This issue of *Current Science* also reproduces the text of introductory articles in the *Collected Works* which provide a wide ranging view of her impact on crystallography worldwide.

I had the rare privilege of editing the *Collected Works* and the even greater privilege of having known her for three decades. This may be the place to look back upon my association with her*.

Seeking Dorothy

The *Bible* says seek and you shall find. Yes, I sought Dorothy since the early 1950s, when I was charged with and accepted the responsibility of building up a school of X-ray crystallography in Bangalore; But I found her only a decade later in 1964. When I had read most of her papers in the fifties I felt that she was foremost amongst those who were changing the face of X-ray crystallography, in that she was solving structures of substances whose structures were quite unknown, thus elevating the very status of the science of crystallography. I felt she could be the salvation of crystallography in India if Indian crystallographers could hitch their wagons to her. I longed that my students after obtaining their Ph D degrees in India could work with her, get inspired by her, come back to India and contribute, if possible, to the new wave in crystallography she had started.

Strangely enough and to my utter surprise I found that Dorothy had heard of me and my struggles in India with multiwavelength anomalous scattering techniques. She told me that she had heard of me from the late Gopinath Kartha (who met her in Oxford on his way to USA to work with David Harker on ribonuclease) and also, as far as I was concerned, most unexpectedly from the late N. V. Belov, the renowned Soviet crystallographer, who had met me in India in the fifties. She sent some gentle enquiries as to whether I could spend a year or two with her trying out the anomalous scattering methods in larger molecules, particularly in proteins like insulin. I informed her that she could do much better by offering a fellowship to my student K. Venkatesan (Van) who was just finishing his post-doctoral year with Jack Dunitz in Switzerland. This I thought could be the thin end of the wedge by which my students could join Dorothy and she too could have an opportunity of judging their quality and that of the Bangalore crystallographers. Dorothy did offer Venkatesan a fellowship. It was a successful experiment because since then 7 or 8 of us from Bangalore have worked in Dorothy's laboratory in Oxford and have tried to imbibe her spirit and culture of crystallography. I understood that Jack Dunitz himself strongly recommended Venkatesan to Dorothy for which I shall always be very grateful to him.

My going to Oxford to be with Dorothy is another story. I conjecture David Phillips (now Lord Ellesmere), who gave the beautiful inaugural lecture in the symposium, played a vital role in it. He came for a conference convened by G. N. Ramachandran in Madras. I was then at IIT Madras. As soon as David came he told me that he would like to have a long chat with me. I suspected that he had come to meet me on behalf of Dorothy. On a free day I arranged for David and myself to go to Mahabalipuram, one of the gorgeous beaches close to Madras. We had a long chat there. I feel that he must have given a good chit about me to Dorothy because a few days after his return I got a letter from her inviting me to Oxford offering me a senior fellowship saying that she would also need my help for looking after her Ph D students when she would be away in Ghana with her husband Thomas. I was greatly flattered with Dorothy's offer and I accepted it with alacrity and thanked my stars.

Looking after Dorothy's students was really no problem at all for they did not need any looking after. During my stay in Oxford I had the pleasure of seeing a group of young talented crystallographers flowering. Every week each one of them would come and tell me what they had done. I put on a wise look and made a few comments and I was told later by Dorothy that they were very useful to them. I also found that often the problems that were being tackled in Dorothy's lab by her students were indicative of her innovative thinking. For example, one of the problems was solving the structure of a comparatively small molecule in a crystal that displayed non-crystallographic symmetry. The solving of the crystal structure itself was by no means difficult but I feel what Dorothy had in mind was to investigate whether, after refining the structure, any phase relationships emerged due to the presence of the non-crystallographic symmetry. Dorothy's lab was one of the earliest ones to combine the photographic method and a computer-controlled microphotometer for the quick collection and indexing of crystallographic data. She foresaw that photographic methods may probably finally replace diffractometric ones, especially when data on hundreds of thousands of reflections had to be collected, indexed and their intensities measured. This work was done in her laboratory long ago and in my view paved the way for the later sophisticated methods which were developed afterwards and which are now in vogue. Dorothy's lab was amongst the earliest to cool protein crystals to reduce their being denatured by X-radiation. She was amongst the earliest to use computers for solving the structures of large molecules.

---

*Based on an after dinner speech delivered at the Royal Society, London on 12 July 1996. The speakers at the meeting included Lord Phillips of Ellesmere, Prof. David Blow, Dr Bill Duax, Dr Peter Roach, Dr Phil Evans, Prof. Jenny Glusker, Prof. Tom Blundell, Prof. Guy Dodson, Prof. Jack Dunitz, Prof. Michael Rossman. Sessions were chaired by Prof. Louise Johnson, Dr Eleanor Dodson, Prof. Bob Williams, Dr Margaret Adams, Dr Max Perutz.

New phasing techniques

Dorothy was always looking out for new techniques of phase determination which she could apply in her work. It was only recently that I knew from David Sayre that it was Dorothy who invited him to Oxford to develop his now-renowned triplet method. When the Patterson synthesis came out she adopted it and mastered it. One has to read her Patterson Memorial lecture to know about her views on this subject and how she used this technique all her life. When the Bijvoet method of phasing using anomalous scattering was published she got into it heart and soul and tried it out on two fairly large non-protein molecules – cobyric acid and monocarboxylic acid of Vitamin B_{12}, which were in my view landmark structures to be solved *completely* using *only* anomalous scattering methods. Dorothy was obviously building stepping stones for her to use the Bijvoet method for solving the insulin structure. Here again many innovative techniques for using anomalous scattering were developed in her laboratory. For example, in zinc insulin, HgI_4 was introduced to see whether a cluster of anomalous scatterers would be of use in phasing. It was shown that it was not so useful. Also, new techniques were evolved for calculating the contributions of the heavy anomalous atoms alone, using simultaneously, anomalous and isomorphous data. This definitely played a major role in the final solving of the insulin structure. At the symposium Max Perutz has described in his inimitable manner how Dorothy attracted his attention to Bijvoet's suggestion of using the multi-isomorphic technique for phasing and how she even berated Max for not having picked this out from Bijvoet's famous 1951 paper and in having lost time in not immediately commencing using this method for solving the haemoglobin structure. We all know that the final solution of the structure depended much on this method.

What surprised me greatly was that as early as 1964–65 Dorothy discussed with me the three-beam interferometric method of using Renninger reflections suggested by Lipscomb and Fankuchen (1949), and earlier by Bijvoet and Macgillavry (1939). Most practising crystallographers would not even have heard of the method at that time. She, however, knew of the valiant effort Ben Post was putting in to make the method work which he finally perfected only in the late seventies. When she asked me whether this interferometric method could be used in the case of proteins, my reply at that time (1964–65) was 'If Renninger reflections could be observed in protein crystals then there was no reason why it could not be used. However I felt that the experimental methods involved may prove quite formidable'. I still do not know whether my answer was correct or not, but this method is now being pursued by many like Weickert, Hummer and others and they seem to have succeeded in determining the phases of a few intense reflections in lysozyme.

When anomalous scattering was discovered also in neutron scattering, Dorothy asked me to investigate whether this could be applied in the phasing of very large molecules. When I found there was a possibility of doing this by putting in an anomalous scattering isotope into the structure and using the appropriate neutron wavelength, she immediately got insulin crystals doped with the required cadmium isotope and put them in the neutron beam of the Harwell reactor. This was in spite of the fact that her mentor, the great J. D. Bernal, had told us both categorically that while the idea was basically correct the intensity of the neutron beams from the then existing reactors may not be sufficient to give any definite result. As expected, Dorothy's experiments proved to be unsuccessful. But to my mind this was of no consequence; it just showed the spirit with which Dorothy pursued new ideas.

Since 1933 Dorothy has been writing long critical reviews of crystal structures (see *Collected Works of Dorothy Crowfoot Hodgkin*, Vol. 3). The first one was in 1933, a 52-page article. In this she says, 'The methods of crystallography have not radically changed but in the past two years they have acquired additional certainty and precision. Fourier analysis which is so laborious has been undertaken in a few laboratories.' These reviews by her are so thorough and so critical that even the scientists who solved the structures would have gained much by reading her reviews. I feel that it was during this process of study for writing these reviews that she acquired her intimate knowledge of inter-atomic distances and bond angles in molecules under different conditions as also molecular configurations and orientations which proved invaluable in her later work.

In another review she welcomed the Patterson technique and explained it in some detail. She applied it almost immediately in its three-dimensional version for solving the structure of cholesteryl iodide. I remember learning all about the intricacies of the Patterson technique from her clearly written paper. She made it look so simple. She admonished crystallographers for not sharpening the Patterson maps which gives much more information and is much easier to interpret. She was a master of the Patterson synthesis. I am reminded of Max Born saying of C. V. Raman, 'His mind leaps over mathematics'. This could apply to Dorothy as well. Dorothy could deconvolute any Patterson map in her mind and deduce exactly where the atoms should be situated.

As soon as I came to Oxford I had the unique honour of sharing for three weeks the same office as Dorothy; indeed I also shared a part of the extra large table she used. I sat on the other end watching her work. When she worked her concentration was incredible. Nothing or no one could distract her. She always lightly hummed a tune and *invariably* had a light smile on her face when working on a structure. She held a molecular model in one hand and sheets of Fourier maps made using approximately estimated phases and sheets and sheets of 3D sharpened Patterson maps in the other. She used to pick up the model and the Fouriers and the Pattersons and study them most carefully to derive the positions of the atoms. To do all this it would appear as though she needed more than two hands and that is why I was very impressed with Maggie Hamblin's insight in the painting of Dorothy – a picture which is now in the National Portrait gallery – in which she has represented Dorothy with many arms and she looks almost like one of the many-armed fierce goddesses of the Hindu Pantheon. We are told by those who know these matters, that goddesses are created by the Almighty to do a specific job which normal human beings cannot accomplish. In the case of Dorothy it was obviously for solving structures which most mortal crystallographers could not. But one aspect of this portrait I do not like is the fierce face Dorothy has been given. Dorothy's face was always calm with a smile. It always radiated peace and tranquility.

Suddenly the humming would stop and she would have a beatific smile on her face. This was indicative of her having plucked out a few atoms from the entangled web of Pattersons and Fouriers and placed them in their right position in the structure.

Now a few words about Thomas Hodgkin. One must read Dorothy's biographical and historical papers which are published in the *Collected Works* to see how much study she puts in to write these. They are filled with quotable quotes. In the biographical memoirs of Kathleen Lonsdale Dorothy quotes, 'For a woman to become a first class scientist she must first of all choose a right husband.' Dorothy no doubt chose extremely well. I knew Thomas Hodgkin very well. We became good friends and we spent hours together conversing and arguing. He had a sharp and a quick tongue but there was absolutely no malice in him. He was a scholar with a deep knowledge of history and the classics – also languages like Latin, Greek and Arabic. He had a remarkable sense of humour which could keep everyone laughing most of the time.

In preparation for a later story I must mention here that both husband and wife had the disconcerting habit of falling asleep when one was talking to them, thus sapping away much of one's self-confidence. When Dorothy went to Stockholm to receive the 1964 Nobel Prize, Thomas also went. In one of the Swedish newspapers there was a picture of Jean Paul Sartre who had refused the Nobel Prize and under the photograph there was a sub-title 'He was not there'. Next to it was another photograph with the legend 'Neither was he'. It was a beautiful and clear picture of Thomas soundly asleep during the prize-giving ceremony.

When Dorothy came to India as a Raman Visiting Professor, Thomas accompanied her. Unfortunately the Bangalore weather did not suit him and his asthma and emphysema worsened and he fell seriously ill. We continually telephoned his doctors in Oxford who told us that on no account must he be moved and there must be no jerky motions at all as his frail lung tissues may collapse at any time. We took all the requisite precautions. I will not tell you the story how as we could not move him into the clinic, as it were the mountain went to Mahomet; in that a big X-ray machine was brought from the clinic to the IISc guest house to take the X-ray photographs of Thomas' lungs. After sometime I noticed that Dr A. R. Pai, our doctor in attendance, after giving all the requisite medication was chanting *mantras*. He told me that all the possible efforts by human beings had been made and it was time to seek divine intervention and he requested me that I should promise to pay rupees thousand to the god of the Seven Hills, Venkateswara of Tirupati if Thomas survived this attack. I told Pai that I did not believe in all this. Pai's reply was exactly the one Neil Bohr gave when he was asked about the horseshoe hanging in his office – 'it works even if you do not believe in it'. Fortunately for all of us, Thomas became well and Pai asked me whether I had sent in the thousand rupees to the temple of Lord Venkateswara. When I said I had not, Pai said, contract is a contract, even if it is made in one's mind and so I must send rupees thousand immediately to the Tirupati temple, particularly as the party of the second part had kept up his end of the contract. So without further ado I sent a demand draft of rupees thousand to the temple at Tirupati*.

In 1982 we got a letter from Dorothy saying that Thomas had died. It was sad. When we saw her next, there was a change: something was missing, Joy had flowed out of her and she appeared far more pensive and serene.

Dorothy often said that she greatly regretted that the four persons – P. P. Ewald, J. D. Bernal, A. Patterson and J. M. Bijvoet were not awarded the Nobel Prize, as they were the persons who started it all and cut new and successful pathways in X-ray crystallography. She also was keen that the Pugwash organization should also be honoured by a Nobel Prize for peace. (This did happen in 1995.)

I have often been asked when I got the idea of publishing Dorothy's Collected Works. I remember the exact moment when this happened. When Dorothy and I visited North-Bengal University, in Siliguiri we were close to the foot hills of the Himalayas. Dorothy who never asked anything for herself said that she would like to view the Himalayas and see at least some of the high peaks. We went up to Darjeeling in a hired ramshackle car. Dorothy could not stand even the heights of Darjeeling and was quite sick and I with foolhardiness did not cancel the visit. Early in the morning we stood on Tiger Hill and saw the sun before it rose, picking up at some of the highest peaks starting with great Mount Everest. Finally, we saw it rise and the Kanchanjunga appeared as a pyramid of gold bathed in the golden sunlight in front of us. It was one of the most magnificent sights I have ever seen, comparable only to two of Natures grandest spectacles I have seen, the Grand Canyon in the US and the Victoria Falls in Africa. It was at that time standing at Tiger Hill along with Dorothy, when she was viewing and surveying the high peaks of the Himalayas and I was seeing Kanchanjunga that I got the complete import of the sentences often repeated by the late S. Chandrasekhar, the renowned Chicago astrophysicist:

---

*There is a foot note to this story. When Thomas was passing through the crisis Dorothy had to give the inaugural lecture at a symposium. She appeared at the proper time, and reportedly gave a memorable lecture. No one would have guessed that she had just left her husband fighting for his life in the guest house just a kilometre away.

> *'The pursuit of science has often been compared to the scaling of mountains, high and not so high. But who amongst us can hope, even in imagination, to scale the Everest and reach its summit when the sky is blue and the air is still, and in the stillness of the air survey the entire Himalayan range in the dazzling white of the snow stretching to infinity? None of us can hope for a comparable vision of nature and of the universe around us. But there is nothing mean or lowly in standing in the valley below and awaiting the sun to rise over Kanchanjunga.'*

When I was with Dorothy on Tiger Hill, I suddenly got the idea that budding young crystallographers of the world may gain much if at least some of the *selected papers* of Dorothy could be published. I did not ask her permission then. Six years later in 1985 when I went to her home, Crab Mill, in Ilmington I asked her and her answer was a categorical *no*. Dorothy said that she had so much work still left to do. She also said that if I took up this project I would ask her to write the introduction which she could ill afford to do at that time. Later in 1991 I again visited her in Ilmington. She had had a fall and had broken her hip-joint and she was immobile and confined to a wheel chair. She was a pathetic sight. One felt extremely sorry for her. She looked so fragile and the main discussion then with the health workers was how to give her a bath. When this engineering problem was solved she looked at me with a smile and said, 'I think you could now go ahead and publish my Collected Works.' I was extremely happy. Almost immediately she said with another charming smile that she would be leaving in a day or two for the Lindau conference of Nobel Prize winners. I was surprised and shocked and wondered how she could do it in her state of health. But she did go in the wheel chair along with her niece. One could not but admire her courage and her indomitable spirit.

It is said that one does not become a great scientist by tackling insoluble problems but scientists like Rutherford and Dorothy who changed the very face of science did take up problems which to most were obviously insoluble, but by their sheer genius they solved them. In this sense they justified Peter Medawar's definition of science as 'the art of the soluble'.

S. Ramaseshan

Understanding the sun

The sun has been held in awe and wonder in the human mind from time immemorial; all along the course of development of knowledge, many attempts have been made to properly understand this heavenly object. The early telescopes employed by Galileo spent considerable time for solving the mystery of the strange markings on the sun; remarkable periodicity which was noticed in their appearance had opened up a series of questions, which continue to the present day. Observations through the ages by employing numerous techniques and devices continued bringing out a flood of new information, keeping scientists busy in unfathoming the mystery of this heavenly splendour.

The pathway to gathering the data has not been smooth; there have been many hurdles in this task. The day-night cycle at any observatory has kept the sun hidden from view for half the time. To circumvent this limitation, scientists have established chains of observatories all around the globe; but still the Earth's atmosphere has always prevented an unhindered view, by disturbing images and absorbing bulk of radiations which bring messages from the sun. Finally an observatory has been floated in space, far out of our planet which now provides a continuous, unrestricted view of the sun all the year round. An account of this unique observatory SOHO, and some question for which answers are awaited appear in this issue (**page 437**).

J. C. Bhattacharyya

Subhas Mukerji

Subhas Mukerji was responsible for the birth of India's first 'test tube baby' in October 1978. Three years after the event, he ended his life in 1981. In the intervening period, the medical establishment aided by an uncaring and unresponsive government machinery, instituted enquiries conducted by committees with suspect credentials, used the weapon of 'transfer' and eventually discredited Mukerji and drove him to his end. Many years after the event, T. C. Anand Kumar (**page 526**) analyses Mukerji's scientific work and comes to the remarkable conclusion that Subhas Mukerji was indeed the 'architect of India's first test tube baby'. Anand Kumar is in fact credited with being the leader of the team that orchestrated India's first 'official test tube baby' in 1986. The disheartening tale of Subhas Mukerji should make us pause to reflect on the need for balance and reason in assessing scientific claims. Anand Kumar's essay, however, reassures us that the tradition of scholarship is still alive and well.

CURRENT SCIENCE

Volume 72 Number 7 10 April 1997

CORRESPONDENCE

Of politicians and theologians: The post-Dolly scenario

As usual, the conclusion seems to be that, where evil is concerned, humans seem to have a monopoly.

—Colin Wilson

History is witness that all great scientific achievements have usually been followed by frenzied and irrational doubts, usually expressed by political and/or religious leaders – the self-appointed guardians of our society. The alchemists of old, who laid down the foundations of modern chemistry were hounded (and also cultivated according to the need of the hour) in the medieval period. Copernicus was persecuted for propounding the theory of a heliocentric universe. When Edison invented the carbon filament lamp in 1879, William Preece informed the House of Commons that the concept of electric light in homes was fanciful and absurd. For fear of the Inquisition, Leonardo da Vinci spent several years secretly designing prototypes of flying machines which uncannily resemble the helicopters of today. More recently, computers and robots were viewed with suspicion and fear that these would eventually take over the world as rulers of mankind. However, anyone, who has been even remotely associated with computers and robots will be well aware as to how fragile and dependent these machines are on humans for their operation and maintenance.

When the world woke up to the birth of Dolly, a cloned 'true-to-type' sheep at the Roslin Institute, Edinburgh, several scientists and leaders of different hues issued statements for and against such scientific researches. As the Roman Catholic Church has long expressed its opposition to any form of reproduction divorced from the sexual act, the Vatican, in a knee-jerk reaction, issued a statement that every person has the right to be born in a human way and not in a laboratory. Several persons in the world today, technically known as test-tube babies therefore, have no right to exist because they were conceived in test-tubes instead of a human womb. Although, taking the medico-legal aspects into consideration, they were born in a human fashion, only conceived artificially.... The arguments are endless.

As any primary student of biology knows, the birth of a new organism is not confined to the sexual union of gametes alone; vegetative propagation, asexual reproduction and even parthenogenesis are common phenomena in the world of biology. From simple cross-breeding and grafting to somaclonal hybridization and oligonucleotide-directed *in vitro* mutagenesis – the twin sciences of genetics and molecular biology have evolved with such gigantic steps that creating either a biotype or an identical clone has become a routine affair rather than a source of wonder. 'True-to-type' plants have been produced by tissue culture for the past several years. Oncologists have been using cloning techniques to study the origin and growth of cancer cells. Then why the hullabaloo if a true-to-type sheep or a couple of simians have been produced through cloning techniques?

If the phenomenon of giving birth to a new being is a Divine Act, it should not be confined to mammals alone but should also be applicable to the plant kingdom and lowly invertebrates. While the author is no authority on theology or metaphysics, it is apparent even to a layman that God should not be defined according to the limited vision of our religious and political leaders. Scientific inventions and discoveries should not be looked upon as a threat to God's existence but as another manifestation of His Divine Presence. Satellite TV and space travel by humans do not imply that God is dead. One need not revert to the Stone Age, simply to acknowledge the existence of God.

The US administration has issued a directive, banning the federal funding of research on cloning of human beings. Is it really justified? Can we arrest the progress of science with a political ban? Can important and significant scientific discoveries simply be wished away? It is unfortunate that the world did not act with equal alacrity to ban nuclear weapons of mass destruction. It appears that we are heading towards the Middle Ages where scientific ideas not in consonance with the limited vision of politicians and religious leaders were banned and the scientists put to death.

Coming back to Dolly, Steven Spielberg, in his sci-fi magnum opus, *Jurassic Park* had envisioned the re-birth of dinosaurs through cloning. The public lapped it up with delight as it had lapped other sci-fi fantasies in *2001 – A Space Odyssey*, *Demon Seed* and *Star Wars.* However, while the public is relatively calm and scientists delighted with the immense possibilities of cloning techniques, it was left to our political and religious leaders to stir up a controversy and contribute to mass hysteria. Perhaps for publicity, if not for votes.

It has been truly said that more powerful than a thousand armies is an idea whose time has finally come. Just as by banning a book, one cannot ban the idea behind it; by banning researches on cloning in humans, one cannot ban the immense possibilities behind such technology. Moreover, it should be remembered that cloning is the biological equivalent of photocopying. To use a crude analogy, any layman can photocopy a Shakespearean sonnet from a book but it takes God in His munificence to produce a Shakespeare in a millennium. However, we are digressing. Perhaps the actual fear is not of cloning technology *per se* but the apprehension that the technology may be misused to produce a race of 'superior' Anglo-Saxons, lending an almost prophetic touch to Colin Wilson's observation.

Ranchi College, Ranchi University,
Ranchi 834 008, India

Biosafety of transgenics

I have read with interest the article 'Transgenic plants and biosafety concerns in India' by P. K. Ghosh (*Curr. Sci.*, 1997, **72**, 172–179). It brings out all the issues that have been raised regarding the biosafety of the transgenic plants, and the procedures adopted in India for the clearances required at various levels for developing, evaluation, upscaling and commercial cultivation of transgenic plants. The latter information should be extremely useful for the researchers working, or intending to work, in this area, especially the young research scholars, who develop such plants while working abroad and wish to bring transformed cell cultures or plants to their own laboratories back home. However, while reading the article it was felt that it only echoes the concerns that have been raised[1–3] but fails to bring out the widely accepted viewpoint of the plant geneticists and breeders especially in North America, Organization for Economic Co-operation and Development (OECD), China and Australia where, as stated by Ghosh, transgenic crops will be grown over an area of over four million hectares this year. Most of these countries, in the past, have shown greater concern for the environmental issues than in India.

Rissler and Mellon[1] argued that (i) The r-DNA methods are more powerful tools for genetic manipulation than the conventional methods used by the breeders, so far. (ii) Prior to the r-DNA methods, genetic manipulations were confined to the use of genetic variability in the primary, or at best, the secondary gene pool of the crop species. (iii) With the new techniques, genes of a large variety from any living organism or a synthesized gene can be expressed in plants, while the conventional methods were limited to replacing alleles or their deletions.

They therefore inferred that r-DNA methods may be linked with 'greater unpredictability' in comparison to the conventional methods, which are limited to genetic manipulation at cellular level alone. In this context, some of the decisions of the National Experts on Safety in Biotechnology of the OECD[2] are very pertinent. They have recognized that 'the safety of an organism is independent of the process of genetic modification *per se*. It is the characteristic of the organism, including new traits, (however introduced), the environment and the application that determine the (likelihood of) risk of the introduction.' Thus, the environmental risks from the transgenic crop plants also apply to the cultivars with similar properties developed using the conventional methods of plant breeding. An insect-resistant crop cultivar developed using inter-cultivaral hybridization or distant hybridization poses the same risk as the one developed by using the genetic engineering methods. Further, it has been accepted that 'the same physical and biological laws control the behaviour of the organism, whether modified by conventional or r-DNA techniques'. Thus the risk is based on the characteristic of the organism, the modified trait, the environment in which the crop is grown, the interaction between these and the intended application.

While examining the environmental risks from the transgenic plants, it should be recognized that all human activities cause some environmental perturbations. Cultivation of large areas with single species by itself has adverse effect on the environment, even without the use of any fertilizers or pesticides, but can the present human civilization survive without agriculture? There is always a certain amount of risk in all activities which have been accepted in our daily life on the basis of the risks verses the benefits. In the early phase of the r-DNA technologies the 'fear of the unknown' not only in the public but even among the geneticists and molecular biologists led to an extremely cautious approach. However, as the experience with transgenic plants has shown, they do not pose greater risks than the crop cultivars developed using the conventional breeding methods. Yet, as has been pointed out by Deshayes[4] regulations have been implemented to avoid environmental risks. Hence, each crop–transgene combination calls for risk–benefit analysis before initiating the experiments and at all further stages of upscaling.

The major environmental risks from transgenic crops raised and as mentioned by Ghosh are: Weediness of the transgenics (not covered by Ghosh); Gene flow into other cultivars, weedy and wild relatives; Development of new strains of viruses on transgenic virus-resistant plants; Effect of transgenic pesticidal products on non-target organisms; Overcoming the resistance mechanism of the transgenes; Safety of the workers and of food items obtained from transgenic crops.

These have been extensively examined[2,3,5–7] and it would not be appropriate to elaborate them here. Most of the above risks apply to crop varieties developed using conventional methods of breeding and are accepted as a part of the breeding strategy. Though these risks cannot be ignored, it is important to consider the number of independent events that would be required, and the probabilities of their occurrence. For instance, the gene flow into other crop cultivars, wild and weedy relatives, presence of sexually compatible wild and weedy relatives of the crop, flowering phenology of the crop and wild weedy relatives, pollination mechanism, means of pollination, same or different insect species visiting the crop and related species, extent of out-crossing in self-pollinators, pollen tube growth and fertilization after pollen deposition, seed set, viability of seed set under field conditions, germination, growth and fertility of such hybrids and. their natural back crossing with wild and weedy relatives would determine the gene flow. The major concern is for the spread of transgenes conferring resistance to herbicides into wild and weedy relatives which could make them resistant to the commonly used herbicides. Even without growing any of the transgenic crops and with limited use of herbicides in Indian agriculture, development of herbicide resistance in weeds has been observed in wheat fields in Punjab. With the import of semi-dwarf rice and wheat cultivars in the mid-sixties, their extensive cultivation since then has not resulted in any appreciable spread of the semi-dwarfing genes into other cultivars.

Transgenic crops can contribute a great deal towards increasing crop productivity, enhancing the stability of the yield, reducing production costs and use of toxic chemical pesticides and consequently the adverse environmental impact of the production systems. Shelf life of the fruits and vegetables can be enhanced to reduce post-harvest losses. Therefore advanced countries have adopted a more pragmatic approach based on risk–benefit analysis.

India has lagged behind China and other developing countries of Asia in field evaluation of transgenic crops. The national efforts in developing such crop cultivars with desirable agronomic traits would take some more time to reach field evaluation. Meanwhile, as stated by Ghosh, two requests for field evaluation of transgenic materials developed abroad and imported by private sector seed companies have been approved. Many other private companies, national and multinational, wish to bring such materials, which have already been approved abroad, in our country. They however, have apprehensions about timely environmental approvals and protection of the Intellectual Property Rights. For environmental clearances experiences gained in other countries should help us in arriving at our own decisions for upscaling and approvals for commercial cultivation instead for repeating the experiments in our environment to establish the safety of specific crop–transgene combinations. At the same time, the scientists aiming to develop transgenic crops with their own efforts should plan ahead to provide all the biosafety data for their constructs. Further, after the approval of the Genetic Engineering Approval Committee of Ministry of Environment and Forests, the transgenic crop varieties should be treated like any other crop varieties developed by the private seed companies or the publicly funded research organizations by the Ministry of Agriculture and the Central Seed Certification Board. There is also an urgent need to create greater public awareness on the biosafety aspects of transgenics in comparison with the conventionally developed crop cultivars, as some environmental activists can create a scare in the public mind based on imaginary issues.

Indian science as cultural heritage

The post-independence generation of the scientific community has grown up in, and contributed significantly to, the slightly haphazard and breathless expansion and proliferation, both horizontal and vertical, of scientific and technical institutions in the Government, academic and private sectors. No other ex-colonized country – China excepted – has engaged in such a spree of scientific run-making, by strokes all around the scientific field, not all of which can be characterized as elegant or worthy of emulation in the matches to come. But there is no gainsaying that the batsmen, including the scientific cross-bat wielders, have clocked-up a respectable total on the board.

However, one inevitable casualty of this style of play has been the lamentable loss of awareness, appreciation and significance of the cultural heritage and related fine-structure of our scientific endeavour that has been inherited by the children of the post-independence generation.

The celebrations of the 50th anniversary of our Independence provide an historic opportunity to repair and restore the physical artefacts of this inherited scientific legacy. I have in mind such sites as the scientifically constructed infrastructure of our historic maritime trade and astronomical observatories; such legacies as the laboratory of Ronald Ross in Hyderabad, the great trigonometric survey, the Pasteur Institute, and the artefacts belonging to the Allahabad–Calcutta 'research axis', which axis was closely associated with the freedom movement.

We are, of course, notorious for not having any sense of history at all – and that goes also for several members of the scientific leadership as well. So, the primary purpose of the above exercise would be to establish and convey a sense of connectivity between the present and the efforts, both modest and titanic, of the principal actors of the immediate and more distant past. Without an established and transmitted connection with the artefacts and the actors of the past, many of the present generation, and an alarming number of the next, will view the Indian scientific enterprise as an imported consumable, merely locally import-substituted in hard times, and not even that when money has been more comfortably provided. One of the many adverse consequences of such a happening will be that, although we will be able to identify – in parts even with justifiable pride – science in India, we will be hard-put to identify, map and transmit to the generations to come the continuing story of Indian science.

Extinct species

Khoshoo (*Curr. Sci.*, 1996, **71**, 506–513) has rightly suggested that India needs a National Biodiversity Conservation Board and it is one of the most welcome suggestions which would help to save our rare species otherwise, they would undoubtedly become extinct if no tangible efforts are made to protect them. However, he has given a sizable list of plants which are alleged to have become extinct in India. Included in this list are two species of the genus *Isoetes* L. (Isoetaceae: Pteridophyta), e.g. *I. dixitei* Shende and *I. sampathkumaranii* Rao, a plant to which we have devoted three decades of pointed attention.

I. sampathkumaranii was initially described by Rao (*Curr. Sci.*, 1944, **13**, 286–287) along water margins in shallow depression in granite rocks from Government Botanical Gardens, Bangalore. This species might have become extinct as its type locality was subsequently destroyed to beautify the garden in question. Moreover, to the best of our knowledge and belief a search for this species at the above type locality and also elsewhere, has yielded nothing positive. There is no later report of its occurrence during the last 25 years or more from any other region.

I. dixitei was for the first time described by Shende (*J. Univ. Bombay*, 1945, **B14**, 50–52) from Panchgani, Maharashtra as occurring in the shallow rock pools on the Tableland. It is specifically mentioned in the above paper that this species became extinct in 1868; but strangely enough this species was described only in 1945. It is therefore, indeed curious, that the species, which was actually described and brought on record as late as 1945 is said to have disappeared in 1868. Even otherwise this species today continues to occur not only in its type locality, Panchgani Tableland but other Tablelands of Panchgani as well as Mahabaleshwar, Maharashtra. However, its protection is essential to save it from the ravages of extinction.

T. N. Khoshoo replies:

The paper was written with the primary purpose of highlighting an urgent need for a National Biodiversity Conservation Board. The national and international response to such a need was indeed overwhelming. To that extent the paper has achieved its objective.

Among other things, the data about extinction of our biota during the last 100 to 200 years was available only with the World Conservation Monitoring Centre. However, before recording the information from WCMC I wrote the following in the aforementioned paper: 'Though no professional studies have been made on the extinction of biota in India, the following species *appear* to have become extinct'.

Based on Srivastava's information, the WCMC may consider deletion of this particular species from the list of extinct species in India. I also wrote the following in the same paper: 'Although the loss of foregoing (24) species has come to light, there may be many more species which have become extinct. A systematic study has to be initiated by BSI and ZSI involving university system.' Let me hope that credible data on endangerment and/or extinction on Indian biota would be generated in India so that one does not have to depend on outside sources.

Mode of action of isonicotinic acid hydrazide

M. K. Chattopadhyay

Isonicotinic acid hydrazide (isoniazid), or INH, a front line antitubercular drug, was introduced in clinical practice in 1952. But till now its exact mode of action is not clearly known. Though majority of the *Mycobacterial* species are sensitive to 1 µg/ml or a higher concentration of INH, sensitivity of *M. tuberculosis* lies in the range of 0.02 to 0.06 µg/ml of INH[1]. This extreme susceptibility of the tubercular pathogen to INH is a riddle which is yet to be solved.

A number of papers published in the past few years have emphasized the role of the *katG* gene in INH-toxicity. This gene encodes a bifunctional enzyme with both catalase and peroxidase activities in *M. tuberculosis*. Loss of *KatG* activity due to gene deletion[2] or missense mutations[3] was found to be associated with INH-resistance of the pathogen. It was proposed that catalase-peroxidase might convert INH into a metabolically active form *in vivo* or its action on INH might generate toxic oxygen radicals which are actually responsible for the antibacterial properties of the drug. *In vitro* oxidation of INH by the enzyme catalase-peroxidase was also evidenced[4].

Investigations have been performed from time to time to elucidate the molecular nature of the intracellular target of INH or of its active form. Earlier it was known that the drug inhibited mycolic acid biosynthesis in *M. tuberculosis*[5]. Evidence obtained from further studies suggested that its primary target might be enoyl-acyl carrier protein reductase, encoded by the *inhA* gene of *Mycobacterium* and is believed to play a key role in mycolic acid biosynthesis[6,7].

However the postulation about the mode of action of INH in terms of its ability to inhibit mycolic acid biosynthesis failed to explain why *M. leprae* is far less susceptible to INH compared to *M. tuberculosis*. Involvement of some other gene was evident. INH is also inactive against *Escherichia coli* and *Salmonella typhimurium*. In both these organisms *katG* is a part of a oxidative stress regulon containing a number of genes including *aphC* which encodes the small subunit of alkyl hydroperoxide reductase. They are induced by the *oxyR* gene in response to challenge by H_2O_2. Knock out mutations of *oxyR* in *E. coli* and *S. typhimurium* is known to confer INH-susceptibility in them. In a recent investigation *oxyR* was found to be inactivated by multiple lesions in the wild type strain of *M. tuberculosis* which is INH-sensitive. The gene was present in intact form in *M. leprae*. When *oxyR* and *aphC* from *M. leprae* were inserted into *M. tuberculosis* through cosmid vector, the tolerance of the tubercular pathogen to INH was substantially increased. As a plausible explanation of the association of these two phenomena – viz. mutation in *oxyR* and susceptibility to INH – it has been proposed that the function of *aphC* and other genes induced by *oxyR* is to protect the bacterial cell from the metabolically active form of INH and from the free radicals. Due to mutation in *oxyR*, in the wild type strain the drug cannot be detoxified. A constitutive level of oxidative stress response, present in the wild type strain, scavenge the oxygen radicals produced in course of normal metabolism. But in absence of induction by *oxyR* the oxidative defense mechanism of the cell is unable to quench the extra load of free radicals generated in the presence of INH[8].

It is important to remember that though INH is believed to be converted into an active form by catalase-peroxidase, none of the metabolic products of the drug (isonicotinic acid and 4-pyridylmethanol) identified so far in *M. tuberculosis* has any antibacterial activity[9]. With the evidence available at present, toxicity of INH to the tubercular pathogen appears to be a multifactorial phenomenon. Investigation on some other aspects (e.g. mechanism of uptake of INH by *M. tuberculosis*) may provide further clues.

On the orchid, *Bulbophyllum crassipes* Hook. f. in the Andaman Islands

Confusion existed upon the identity and nomenclature of this plant since its record by Hook. f. from Penang in 1907. Orchidologists like Holttum, Ridley, Taylor, Ker, Lindley, Seidenfaden and others made a series of attempts to solve it to a considerable extent. Although Seidenfaden and Wood[1] as well as Satishkumar and Manilal[2] accorded this taxon a specific rank, we would like to support the views of Pradhan[3] and Sarkar[4] giving a varietal status, *B. careyanum* (Hook) Spreng. var. *crassipes* (Hook. f.) U. C. Pradhan to the Indian plants. The diversity of the scapes and spikes with the colour variation of the flowers would support this treatment, ideally under *B. careyanum* (Hook) Spreng. var. *crassipes* (Hook. f.) U. C. Pradhan as it differs only by the column feature. It is widely distributed from Sikkim through Assam to northern and northeastern Thailand, with several records from Peninsular Thailand and possibly from Malaysia. The occurrence or distribution of this orchid in Andaman and Nicobar islands has not been mentioned by Vasudeva Rao[5], Lakshminarasimhan and Rao[6] in their enumerations. However, Satishkumar and Manilal[2] have mentioned its distribution in these islands. To the best of our knowledge there are no previous records of its collection at Port Blair except the present ones of South Andaman. It closely resembles *B. cupreum* Lindl, but is quite different from it.

Epiphytes: Pseudobulbs are 6–8 cm distant, faintly 4–5 angled or smooth + 3 cm across. Leaves solitary, fleshy, up to 15 cm long. The scapes holding dense spikes measuring up to + 8 cm long, usually arising from the base, occasionally from the tip of the pseudobulbs. Flowers brownish yellow with maroon spots, remain open for 15–20 days, wilt and fade to dark brown. Growing on *Heritiera littoralis* Dryland, along the littoral belt, in the back mangals where it is inundated only during high tide.

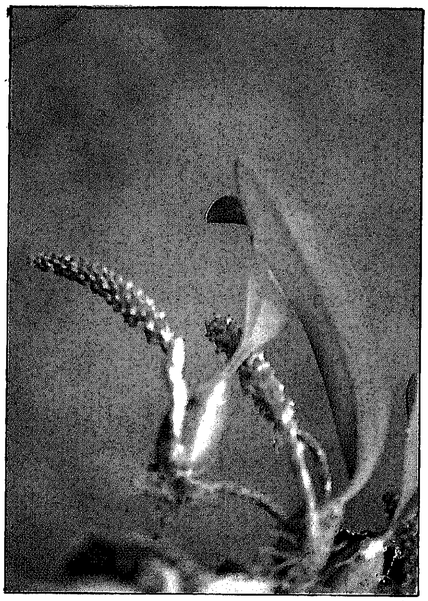

Figure 1. *Bulbophyllum crassipes* Hook. f. from Andaman Islands.

Does statistical significance always imply biological significance

Innate short-term variation exists in biological data; e.g. daily body weights, dietary nutrient intakes, physiological or biochemical indicators of body status like basal metabolic rates, blood levels of vitamins and minerals and so on. Any physical or physiological stress such as physical training programme, weight control regime or drug therapy alters the mean value of these parameters. To test the significance of the difference between mean values of these parameters, usually Student's t test is used. But application of this test sometimes results in a paradoxical situation. The test declares the difference between means to be highly significant but the experimenter feels that the difference is not worthy of attention. The problem is then whether to call the difference a significant one on statistical grounds or to accept intuition of the experimenter that the difference is negligible. Here we illustrate this issue with examples and describe application of a proper test considering biological variation.

Let $x_1, x_2, \dots x_n$ be the observations on n individuals before treatment and $y_1, y_2, \dots y_n$ after treatment. So $z_i = y_i - x_i$ is the difference between ith pair. Consider the null hypothesis of zero difference; viz. $H_0 : \mu_z = 0$, vs $H_1 : \mu_z \neq 0$ and consider the common situation where the variables are normally distributed. Sample size calculations require the specification of type I and type II errors, a 'difference

Table 1. Effect of physical training on body weight in army cadets

	Before physical training		After physical training		Difference		Paired t test		Interval t	
	Mean	SD	Mean	SD	Mean	SD	t	Decision	δ	Decision
Group 1 ($n = 73$)	56.20	3.19	57.07	3.16	0.868	1.33	5.58	Reject H_0	0.7	Accept H_0
Group 2 ($n = 26$)	55.13	2.73	56.20	3.23	1.070	1.54	3.52	Reject H_0	0.6	Accept H_0

Table 2. Per cent absorption of zinc from two test diets

	Before treatment		After treatment		Difference		Paired t test		Interval t	
	Mean	SD	Mean	SD	Mean	SD	t	Decision	δ	Decision
Diets ($n = 24$)	18.2	2.3	19.8	2.2	1.6	2.4	3.2	Reject H_0	1.2	Accept H_0

to detect' for the means, and the standard deviation (SD) which is usually not known. An overestimate of the SD leads to an overestimate of sample size so that the experiment has more power than expected and can lead to the situation of false significance. Secondly a significant result also can be caused by true difference of means less than those the experimenter wished to demonstrate. The probability of this event will be less than the power previously assumed in sample size calculations, but greater than the type I error. Therefore the 'difference to detect' should not only be included in the planning but also in the test procedure. The issue can be addressed by the following type of hypotheses; $H_0 : -\delta \leq \mu_z \leq \delta$ against $H_1 : \mu_z \leq -\delta,\ \mu_z > \delta$.

These problems have been tackled in statistical research ever since 1938 by Berkson[1], Hodges and Lehman[2] and Anderson and Hauck[3]. In 1993 Mehring[4] has suggested the following procedure as a generalization of Student's t test for testing such an interval hypothesis:

1. Define δ on the basis of practical consideration.
2. Calculate $\gamma_2 = (\delta \sqrt{n}/\sigma)$.
3. Reject H_0, if $1 - F_k(|T| - \gamma_2) + F_k(-|T| - \gamma_2) < \alpha$, (1)

where $T = (z\sqrt{n})/s_z$ is usual t statistic, $s_z^2 = \Sigma(z_i - \overline{z})^2/(n-1)$, and F_k is central t distribution with k d.f., $k = n - 1$.

Table 1 gives the data of body weights of army cadets in training in two phases of activity levels five months apart. Interest was to see the effect of training on body weight[5]. The average difference was 0.87 kg. With the paired t-statistic this difference is significantly larger than zero. This difference, however, was not considered to be a physiologically significant one in view of the duration and regularity in diet as well as exercise. Further, the magnitude of the difference is of the order of day-to-day fluctuations in weight of an individual (between 0.5 and 1 kg)[6]. Logically therefore a difference greater than this value is indicative of a real change in weight. So the test with the value of δ between 0.5 and 1 kg the procedure (1) is carried out. For $\delta \geq 0.7$, and σ known from past data, the null hypothesis that 'the difference between means is not significant' is accepted. Thus the test confirms the findings of Edholm *et al.*[6].

If the value of δ is not previously known, one can estimate it by using within individual variation (Table 2). While testing the difference between per cent absorption of zinc from two diets differing in their compositions, both the diets were given to a group of 24 human volunteers for a period of 15 days each, with a washout period between the two experiments. There was a variation in per cent absorption over days in the same individual. Based upon this within-person variability, value of δ was decided to be the intraindividual standard deviation. The usual t-test showed the difference to be significant. However, incorporating intraindividual variation into the hypothesis to be tested and carrying out the test as explained earlier, it was found that the difference of about 2% in the absorption was not really significant to attribute to difference in the compositions of diets.

Similar problems may arise in medical research where intraindividual variation exists in the parameter under study. Application of the above test with interval $(-\delta, \delta)$ constructed on the basis of intraindividual variation will certainly help in proper analysis and interpretation of the data.

OPINION

Biotechnology in India: The technology imperative

Harish Padh

The government should de-emphasize basic research and instead provide infrastructure and technology channels for promotion of biotech sector. Facilities like technopark available to software industry if made available to the biotech industry can spur growth of this biotech sector. This will also facilitate proper technology licensing and transfer and promote growth. On a long-term basis, we should also focus on technology development especially for the diseases of the developing countries.

Global prospects for biotechnology industry

In a short span of 15 years, biotechnology has established itself as a significant factor in health-care industry. In USA it has already gained nearly 10% share of the total pharma market. The biotech industry is just coming out of its infancy (Table 1). Its potential is being tested, realized and used. The public awareness and acceptance will accelerate the process. This sector is expected to expand at least 2-fold by the end of the century and will soon match or surpass the computer industry in size, importance and growth. It holds good promise in a number of areas, specially those for which we have no current treatment. There is a tremendous potential for developing countries like India to apply biotechnology in health-care, agriculture and environmental resource management. In the earlier paper[1] I discussed the current status of biotechnology as an industry sector, in this paper I will discuss how India can best benefit from this new set of technologies.

Biotechnology in India

India has a number of good academic institutions with expertise in basic sciences relevant to biotechnology. India also has a fair number of suppliers and stockists who market required reagents and supplies. There is also a surge in testing facilities, R&D institutions, small medical equipment fabricators, repackers and sellers of relevant imported materials.

India has a rapidly swelling population of upper-class and middle-class, needing newer diagnostics and therapeutics. Moreover, proliferating private medical and hospital care has created a tremendous demand for biotech products. Proliferation of diagnostics is mostly met by imports, primarily because there is a general failure of locally developed diagnostics.

Indian pharma industry

Indian pharmaceutical industry is strong and has the expertise for chemical drugs. It is competing well in bulk drug market, largely due to the more efficient nature of the processes and manufacturing costs. The same can hold true for the biological drugs, but at the moment it has little experience in biotech diagnostics and no experience in biotech therapeutics. India's economic liberalization and signing of GATT and Dunkel Draft clear the way and need for significant R&D activities by pharmaceutical industry. Impending changes in patent law will make it necessary to either develop our own technology or obtain proper licence from others. Globalization of economy and liberalization of our economy make this an appropriate time to seek outside licensing and technology transfer. The Western India (Gujarat, Maharashtra), with more than 50% of the registered pharmaceutical units, accounts for 90% of the pharmaceutical production. This region also accounts for more than 70% of import and export of the pharmaceuticals. The Indian pharmaceutical industry will sooner or later enter in manufacturing of biotechnology-based diagnostics and therapeutics. There is no government institution or university in this region with expertise in this area to help the pharma industry.

Table 1. Ten years history of the biotechnology therapeutics in USA

	1985	1990	1995
Sales ($ in billions)	1.1	2.9	9.3
Revenues ($ in billions)	2.2	4.7	12.7
R&D expenditure ($ in billions)	1.7	2.6	7.7
Number of companies	850	1,107	1,308
Employees	40,000	66,000	108,000

Diagnostics

Worldwide there are about 600 new biotechnology-based diagnostics in the market with a value of about $ 20 billions. Many more are about to enter the market, the most prominent among these will be nuclear probe and PCR-based diagnostics. India relies on imports for many of the immunodiagnostics kits. Many of the locally developed diagnostics have failed, while the imported diagnostics are either unsuitable or expensive.

Therapeutics

Expression of foreign genes in convenient prokaryotic cells and the large-scale production of gene products is now routine. These protein products could have applications as therapeutics, diagnostics, restriction enzymes or industrial enzymes. At present there are about 79 biotechnology-derived therapeutics approved for human use in USA. The total market value of these products is about $ 50 billions. About 150 companies have 700 more products in various stages of clinical trials and development. With increasing acceptability of biotech products, there will be about 200 biotechnology-derived therapeutics available in the market by the turn of the century. In 1987 the number of new drugs (IND, Investigational New Drug) produced by biotechnology had overtaken IND produced by conventional means (chemical and antibiotic drugs). This is an indication of the trend that, in future, new therapeutics will be made by cellular factories using recombinant technologies. At present, there is no locally manufactured recombinant therapeutic product available in the market. Few imported biological therapeutic products are marketed in India, e.g. human insulin and streptokinase.

Factors influencing biotech growth

Table 2 shows various factors influencing growth in a particular segment of economy. For example, in USA the growth is driven by innovation while in Germany it is driven by capital investment and proper technology management. In Thailand (and India?) the factors like cheap labour or availability of raw materials, etc. can spur growth. In India and China, sudden growth is evidenced owing to the rapid opening of huge consumer markets. Thus, India is poised to enter the biotechnology market. Infusion of foreign technologies and collaboration has already taken place in other sectors of economy. It is now time for Biotech/Pharma sector to seek proven technologies from outside. The government should provide proper channel and infrastructure to the pharma industry. This will lead to value-added better stable, tested and validated products in the market. Other governments, including Germany has government-supported agencies for technology identification and import. The SIDCs (state industrial development corporations) should get serious about this sector. In addition, the problems of developing countries (malaria, tuberculosis, etc.) have remained untouched by biotechnology either in India or overseas. These problems will need innovative approaches.

Development of new technologies

India has a good number of government institutions and universities involved in the creation and development of new relevant technologies. We have a chain of CSIR institutions and other places like CCMB, IMTECH, NIPER, NII, IISc, etc. engaged in research and development that may help health-care sector. In spite of this modest but consistent support from the central government, we have not utilized our resources and infrastructure to the fullest. I believe primarily it is the academic nature of these institutions which lack appreciation of industry and the market place, resulting in their inability to help industry.

Commercialization of new technologies

There are a few instances where a usable technology has been developed in an academic institution, primarily for diagnostics. However, in most of these cases technologies failed in development stages or even after marketing. This is another example where academia and industry show lack of understanding and appreciation of each other. Our pharma industry is by and large without significant R&D activities because of lower profit margin. Because academia cannot really do development of technologies, and because the industry is either burnt out by academia or unable to appreciate or afford development of technologies, some useful technologies go undeveloped. The net result is that we in India develop far fewer technologies than what our capabilities are and our demands require. Even fewer technologies are actually commercialized. Therefore, we depend on import of products from abroad to meet our growing needs. This hold true for most of the biotech diagnostics and therapeutics.

Academic–industry relationship

In India the academia–industry relationship has worked quite well for chemical industry and other engineering-based industries, primarily because of IITs. As far as biotechnology is concerned, academic–industry relationship is nonexistent or ineffective. By and large each side has a lack of understanding or appreciation of other. At times it translates into outright apprehension (see *Curr. Sci.*, 1991, **60**, 524–528).

Technology absorption and transfer

Since we do not invent and develop technologies, we rely on import of either products or the technologies. Proper licensing and transfer of proven technologies is not that common in India. The process patent policy helped us to 'improvize' processes and it was not needed to go for proper technology licensing. At the same time, very few government institutions worked to facilitate the absorption of technologies. A noted exception is BRIT, a DAE agency which developed indigenous radioimmunoassay kits and made it so user-friendly for Indian conditions that now about 20 diagnostic radioimmunoassay kits are developed and marketed by BRIT. There are about 200 diagnostic centres throughout India where BRIT-trained technicians operate these diagnostics.

Biotech generic market

In the international market, biotechnology drugs are very expensive. For example, Genetech's tPA is priced at about $ 2000 per injection and streptokinase is marketed at about $ 200 per injection. A genetically engineered Factor VIII used in the treatment of hemophiliacs costs $ 25,000 a year. Imported therapeutics traded in India are exhorbitantly priced (Rs 300 per dose of human insulin compared to Rs 65 per dose of traditional insulin) and about Rs 4000 per dose of streptokinase. What will be our strategy when in three years there will be over 200 therapeutics and vaccines available? Shall we still rely on imports? The next generation of these products will have to be less expensive and more effective. We can provide inexpensive manufacturing base for Indian as well as export market. We should go for proper technology transfer and develop the manufacturing base. In addition, many of the biotech products will be off-patent

Table 2. Driving forces influencing industrial growth

Driving force	Precondition	Strategy	Example
Factor	Factor advantage	Low tech sectors	Thailand, India??
Investment	Mature user industry	Investment in getting foreign technology, joint government and private ventures	Germany
Innovation	Developed science base, mature industry base, venture capital	New companies led development	USA
Market base	Sudden opening of large consumer market	Careful import and promotion of proven technologies	India, China, Eastern Europe, Former Soviet countries

in a few years. Priority could be to manufacture these off-patent products. India with proper technology transfer can develop its niche in off-patent biotech 'generic' market.

Need for licensing and transfer of technologies

We have witnessed that indigenously developed diagnostics have shown less than satisfactory performance in the market. The imported diagnostics are not suitable because they are expensive, not against local pathogenic strains, and with little or no quality and stability controls. In addition, the Indian pharmaceutical industry has little or no experience in modern diagnostics or biological therapeutics. Their approach of process improvization that worked well for chemical drugs will not work in biotechnology-based diagnostics or therapeutics. In addition, the number of newer diagnostics in the international market every year is burgeoning. Therefore, the national interest is better served by systematic approach in identifying, licensing and transferring of appropriate proven technologies.

Need for technology development

There are a few diagnostics developed in the country but overall performance has been dismal. There seems to be a gap of culture, communication or something between the academic and corporate worlds as a net result of which the internally developed technologies have not been designed or developed properly. The products do not reach the market or fail in the market. For a long-term interest of the nation there is a need for local development of technologies, especially against conditions like tuberculosis and malaria rampant in India.

What the government can do?

The growth of biotech sector in USA is innovation-based while in other Western countries it is based on technology transfer and capital investment. We ought to realize that every country cannot have innovation-based sector growth (see Table 2). In fact, in biotechnology it is only USA which has witnessed growth of the biotech sector based on innovation. Rest of the countries, including the Western Europe and Japan, have only minor contribution in innovation-based growth. Therefore, it will be futile for India to pour its valuable resources only in research and hope that we too can have innovation-based biotech sector growth. The government can promote biotech sector by the following two approaches. (i) Provide a good infrastructure including a Biotech Park with the state of art common facilities including laboratory and pilot plant equipment. Contrary to belief, these infrastructure facilities can be made financially self-supportive. Benefits in terms of promoting industry are numerous. Many countries including Taiwan, Korea, Japan, European countries, and even Brazil have Biotech Parks to cater to and promote this sector. In India too there are several technoparks to cater to the computer industry. (ii) Establish technology transfer office where entrepreneurs can approach for available proven technology for licensing. This office can shop throughout the world for availability of proven technology, can advise and help entrepreneurs through the negotiation process, and can help industry to get the best deal on import and licencing of proven technologies. At the moment, only the large companies can afford to do their technology shopping on their own. Medium and small scale industry have no such help in identifying and obtaining proven technology. The emphasis is on *proven* technology, one that is successfully used elsewhere. It is a foregone conclusion that technology import or licensing is a must for the near future. It is also evident that small- and medium-scale industry has not been tapped for biotech sector. It has been observed that many entrepreneurs with good investment capacity but who are not trained in biotech would like to diversify in biotech provided they have some reliable technology sources. It has also been observed that many entrepreneurs who were ignorant of technology transfer ended up loosing money in attempts to arrange for the technology transfer on their own. Both these groups of entrepreneurs could be helped by the proposed technology centre.

In summary, the government should de-emphasize basic research and instead provide infrastructure and technology channels for promotion of biotech sector.

Potential concerns for technology transfer

It may be perceived to be an expensive proposition to go for proper technology transfer. However, we do not have any other option. Proper tech transfer adds only a small percentage to the final retail price. Depending on the expected volume, it may cost between 5% and 10% more to the final retail price. Considering the time and expenses saved, this small price is negligible.

Another apprehension is that we will not get a good technology, primarily because of our reputation as technology thieves. In some cases, individual companies have gotten into agreements which were not designed to their advantage. This is mainly due to our inexperience in evaluation of technology potential and negotiation process. And as we enter international business deals, we will have to face and rectify the reputation we might have. Changing our patent laws will be a step in this direction. Another pitfall is that we only look at USA for the technology source. Companies from many other countries have useful technologies while the market in their own countries is limited. These companies are eager to enter markets like India for its local consumers as well as regional export.

SOHO hunts elusive solar prey

B. N. Dwivedi and Anita Mohan

The Solar and Heliospheric Observatory, SOHO, is a project of international cooperation between ESA and NASA to study the Sun from its deep core to the outer corona and the solar wind. To achieve its goals, SOHO carries a complement of twelve sophisticated, state-of-the-art instruments. In this article, we present a brief account of this ambitious project and highlight some of its achievements since the SOHO spacecraft turned an unblinking eye on a turbulent Sun from its vantage point in space on 14 February 1996.
